

2022

PARTICLE PHYSICS BOOKLET

Extracted from the *Review of Particle Physics*
R.L. Workman et al. (Particle Data Group),
Prog. Theor. Exp. Phys. 2022, 083C01 (2022).

See **pdg.lbl.gov** for Particle Listings,
complete reviews and pdgLive.

Available from PDG at LBNL and CERN

The complete 2022 *Review of Particle Physics* is published online by Prog. Theor. Exp. Phys. (PTEP) and on the PDG website (<https://pdg.lbl.gov>). The printed *PDG Book* contains the Summary Tables and all review articles but no longer includes the detailed tables from the Particle Listings. This *Particle Physics Booklet* includes the Summary Tables plus essential tables, figures, and equations from selected review articles.

Copies of this *Booklet* or the *PDG Book* can be ordered from the PDG website or directly at

<https://pdg.lbl.gov/order> .

For special requests only, please email

pdg@lbl.gov

in North and South America, Australia, and the Far East, and

pdg-products@cern.ch

in all other areas.

Visit our web site: <https://pdg.lbl.gov/>

The publication of the *Review of Particle Physics* is supported by the Director, Office of Science, Office of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231; by an implementing arrangement between the governments of Japan (MEXT: Ministry of Education, Culture, Sports, Science and Technology) and the United States (DOE) on cooperative research and development; by the Italian National Institute of Nuclear Physics (INFN); by the Physical Society of Japan (JPS); and by the European Laboratory for Particle Physics (CERN). Individual collaborators receive support for their PDG activities from their respective institutes or funding agencies.

* This *Particle Physics Booklet* includes the Summary Tables plus essential tables, figures, and equations from selected review articles. The table of contents, on the following pages, lists also additional material available in the full *Review*.

PARTICLE PHYSICS BOOKLET TABLE OF CONTENTS

1. Physical constants	6
2. Astrophysical constants	8
Summary Tables of Particle Physics	
Gauge and Higgs bosons	10
Leptons	16
Quarks	25
Mesons	27
Baryons	166
Searches not in other sections	198
Tests of conservation laws	203
Reviews, Tables, and Plots	
9. Quantum chromodynamics	206
10. Electroweak model and constraints on new physics	207
11. Higgs boson physics, status of	209
12. CKM quark-mixing matrix	211
13. <i>CP</i> violation in the quark sector	213
14. Neutrino mass, mixing and oscillations	215
15. Quark model	218
22. Big-bang cosmology	220
27. Dark matter	222
29. Cosmic microwave background	223
30. Cosmic rays	225
31. Accelerator physics of colliders	226
32. High-energy collider parameters	228
34. Passage of particles through matter	229
35. Particle detectors at accelerators	236
37. Radioactivity and radiation protection	237
38. Commonly used radioactive sources	239
39. Probability	241
40. Statistics	245
45. Monte Carlo particle numbering scheme	251
46. Clebsch-Gordan coefficients, spherical harmonics, and <i>d</i> functions	253
49. Kinematics	255
51. Cross-section formulae for specific processes	263
52. Neutrino cross-section measurements	268
6. Atomic and nuclear properties of materials	269
4. Periodic table of the elements	inside back cover

The following are found only in the full *Review*, see

<https://pdg.lbl.gov>

VOLUME 1: SUMMARY TABLES AND REVIEWS

Highlights

Introduction

History plots

Online particle physics information

Reviews, Tables, and Plots

Constants, Units, Atomic and Nuclear Properties

3. International system of units (SI)
5. Electronic structure of the elements
7. Electromagnetic relations
8. Naming scheme for hadrons

Standard Model and Related Topics

16. Heavy-quark & soft-collinear effective theory
17. Lattice quantum chromodynamics
18. Structure functions
19. Fragmentation functions in e^+e^- , ep and pp collisions
20. High energy soft QCD and diffraction

Astrophysics and Cosmology

21. Experimental tests of gravitational theory
23. Inflation
24. Big-bang nucleosynthesis
25. Cosmological parameters
26. Neutrinos in cosmology
28. Dark energy

Experimental Methods and Colliders

33. Neutrino beam lines at high-energy proton synchrotrons
36. Particle detectors for non-accelerator physics

Mathematical Tools

41. Machine Learning
42. Monte Carlo techniques
43. Monte Carlo event generators
44. Monte Carlo neutrino event generators
47. SU(3) isoscalar factors and representation matrices
48. SU(n) multiplets and Young diagrams

Kinematics, Cross-Section Formulae, and Plots

50. Resonances
53. Plots of cross sections and related quantities

Particle Properties

Gauge Bosons

54. Mass and width of the W boson
55. Z boson

Leptons

56. Muon anomalous magnetic moment
57. Muon decay parameters
58. τ branching fractions
59. τ -lepton decay parameters

Quarks

60. Quark masses
61. Top quark

Mesons

62. Form factors for semileptonic kaon ($K_{\ell 3}$), radiative pion ($\pi_{\ell 2\gamma}$) & kaon ($K_{\ell 2\gamma}$) decays
63. Spectroscopy of light meson resonances
64. Scalar mesons below 1 GeV

- 65. Rare kaon decays
- 66. *CPT* invariance tests in neutral kaon decay
- 67. V_{ud} , V_{us} , Cabibbo angle, and CKM unitarity
- 68. CP -violation in K_L decays
- 69. Review of multibody charm analyses
- 70. $D^0 - \bar{D}^0$ mixing
- 71. D_s^+ branching fractions
- 72. Leptonic decays of charged pseudoscalar mesons
- 73. Production and decay of b -flavored hadrons
- 74. Polarization in B decays
- 75. $B^0 - \bar{B}^0$ mixing
- 76. Semileptonic B -hadron decays, V_{cb} and V_{ub}
- 77. CKM angles from B hadrons, determination of
- 78. Spectroscopy of mesons containing two heavy quarks
- 79. Heavy non- $q\bar{q}$ mesons

Baryons

- 80. Baryon decay parameters
- 81. N and Δ resonances
- 82. Λ and Σ resonances
- 83. Pole structure of the $\Lambda(1405)$ region
- 84. Pentaquarks

Hypothetical Particles and Concepts

- 85. Extra dimensions
- 86. W' -boson searches
- 87. Z' -boson searches
- 88. Supersymmetry: theory
- 89. Supersymmetry: experiment
- 90. Axions and other similar particles
- 91. Quark and lepton compositeness, searches for
- 92. Dynamical electroweak symmetry breaking: implications of the H^0
- 93. Grand unified theories
- 94. Leptoquarks
- 95. Magnetic monopoles

VOLUME 2: PARTICLE LISTINGS (available online only)**Illustrative key and abbreviations****Gauge and Higgs bosons**

(γ , gluon, graviton, W , Z , Higgs, Axions)

Leptons

(e , μ , τ , Heavy-charged lepton searches,
Neutrino properties, Number of neutrino types
Double- β decay, Neutrino mixing,
Heavy-neutral lepton searches)

Quarks

(u , d , s , c , b , t , b' , t' (4^{th} gen.), free quarks)

Mesons

Light unflavored (π , ρ , a , b) (η , ω , f , ϕ , h)

Strange (K , K^*)

Charmed (D , D^*)

Charmed, strange (D_s , D_s^* , D_{sJ})

Bottom (B , V_{cb}/V_{ub} , B^* , B_J^*)

Bottom, strange (B_s , B_s^* , B_{sJ}^*)

Bottom, charmed (B_c)

$c\bar{c}$ (η_c , $J/\psi(1S)$, χ_c , h_c , ψ)

$b\bar{b}$ (η_b , Υ , χ_b , h_b)

Other mesons

Baryons

N
 Δ
 Λ
 Σ
 Ξ
 Ω

Charmed (Λ_c , Σ_c , Ξ_c , Ω_c)
Doubly charmed (Ξ_{cc})
Bottom (Λ_b , Σ_b , Ξ_b , Ω_b , b -baryon admixture)
Exotic baryons (P_c pentaquarks)

Searches not in Other Sections

Magnetic monopole searches
Supersymmetric particle searches
Technicolor
Searches for quark and lepton compositeness
Extra dimensions
WIMP and dark matter searches
Other particle searches

Notes in the Listings

Triple gauge couplings (TGC's)
Anomalous $ZZ\gamma$, $Z\gamma\gamma$, and ZZV couplings
Anomalous W/Z quartic couplings
Neutrino properties
Sum of neutrino masses
Number of light neutrino types from collider experiments
Neutrinoless double- β decay
Charged kaon mass
Dalitz plot parameters for $K \rightarrow 3\pi$ decays
 CP -violation in $K_S \rightarrow 3\pi$
Heavy Flavor Averaging Group
Charmonium system
Branching ratios of $\psi(2S)$ and $\chi_{c0,1,2}$
Bottomonium system
Width determination of the Υ states
Radiative hyperon decays
 Ξ resonances

1. Physical Constants

Table 1.1: Revised 2021 by D. Robinson (LBNL). Mainly from “CODATA Recommended Values of the Fundamental Physical Constants: 2018,” E. Tiesinga, D.B. Newell, P.J. Mohr, and B.N. Taylor, NIST SP961 (May 2019). The last group, beginning with the Fermi coupling constant, comes from PDG. The $1-\sigma$ uncertainties are given in parentheses. See the full *Review* for references and further explanation.

Quantity	Symbol, equation	Value	Uncertainty (ppb)
speed of light in vacuum	c	299 792 458 m s $^{-1}$	exact
Planck constant	\hbar	6.626 070 15 $\times 10^{-34}$ J s (or J/Hz)	exact
Planck constant, reduced	$\hbar \equiv h/2\pi$	1.054 571 817... $\times 10^{-34}$ J s = 6.582 119 569... $\times 10^{-22}$ MeV s	exact
electron charge magnitude	e	1.602 176 634 $\times 10^{-19}$ C	exact
conversion constant	$\hbar c$	197.326 980 4... MeV fm	exact
conversion constant	$(hc)^2$	0.389 379 372 1... GeV 2 barn fm	exact
electron mass	m_e	0.510 998 950 00(15) MeV/c 2 = 9.109 383 70(5) $\times 10^{-31}$ kg	0.30
proton mass	m_p	938.272 088 16(29) MeV/c 2 = 1.672 621 923 69(51) $\times 10^{-27}$ kg = 1.007 276 466 621(53) u = 1836.152 673 43(11) m_e	0.053, 0.060
neutron mass	m_n	939.565 420 52(54) MeV/c 2 = 1.008 664 915 95(49) u	0.57, 0.48
deuteron mass	m_d	1875.612 942 57(57) MeV/c 2	0.30
unified atomic mass unit (u)	$u = (\text{mass } ^{12}\text{C atom})/12$	931.494 102 42(28) MeV/c 2 = 1.660 539 066 60(50) $\times 10^{-27}$ kg	0.30
permittivity of free space	$\epsilon_0 = 1/\mu_0 c^2$	8.854 187 8128(13) $\times 10^{-12}$ F m $^{-1}$	0.15
permeability of free space	$\mu_0/(4\pi \times 10^{-7})$	1.000 000 000 55(15) N A $^{-2}$	0.15
fine-structure constant	$\alpha = e^2/4\pi\epsilon_0 hc$	7.297 352 5693(11) $\times 10^{-3}$ = 1/137.035 999 084(21) At $Q^2 \approx m_W^2$ the value is $\sim 1/128$.	0.15
classical electron radius	$r_e = e^2/4\pi\epsilon_0 mec^2$	2.817 940 3262(13) $\times 10^{-15}$ m	0.45
(e^- Compton wavelength)/2 π	$\lambda_e = \hbar/m_e c = r_e \alpha^{-1}$	3.861 592 6796(12) $\times 10^{-13}$ m	0.30
Bohr radius ($m_{\text{nucleus}} = \infty$)	$a_\infty = 4\pi\epsilon_0 \hbar^2/me c^2 = r_e \alpha^{-2}$	0.529 177 210 903(80) $\times 10^{-10}$ m	0.15
wavelength of 1 eV/c particle	$hcR_\infty = m_e e^4/(2(4\pi\epsilon_0)^2 \hbar^2) = m_e c^2 \alpha^2 / 2$	1.239 841 984... $\times 10^{-6}$ m	exact
Rydberg energy		13.605 693 122 994(26) eV	1.9 $\times 10^{-3}$
Thomson cross section	$\sigma_T = 8\pi r_e^2/3$	0.665 245 873 21(60) barn	0.91

Bohr magneton	$\mu_B = e\hbar/2m_e$	$5.788\ 381\ 8060(17)\times 10^{-11}\ \text{MeV T}^{-1}$	0.30
nuclear magneton	$\mu_N = e\hbar/2m_p$	$3.152\ 451\ 258\ 44(96)\times 10^{-14}\ \text{MeV T}^{-1}$	0.31
electron cyclotron freq./field	$\omega_{\text{cycl}}^e/B = e/m_e$	$1.758\ 820\ 010\ 76(53)\times 10^{11}\ \text{rad s}^{-1}\ \text{T}^{-1}$	0.30

Table 2.1: Revised August 2021 by D.E. Groom (LBNL) and D. Scott (U. of British Columbia). The figures in parentheses after some values give the $1\text{-}\sigma$ uncertainties in the last digit(s). Physical constants are from Ref. [1]. While every effort has been made to obtain the most accurate current values of the listed quantities, this table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference. The values and uncertainties for the cosmological parameters depend on the exact data sets, priors, and basis parameters used in the fit. Many of the derived parameters reported in this table have non-Gaussian likelihoods and parameters may be highly correlated, so care must be taken in propagating errors. Unless otherwise specified, cosmological parameters are derived from a 6-parameter Λ CDM cosmology fit to *Planck* cosmic microwave background 2018 temperature (TT) + polarization (TE,EE+lowE) + lensing data [2]. For more information see Ref. [3] and the original papers.

Quantity	Symbol, equation	Value	Reference, footnote
Newtonian constant of gravitation	G_N	$6.67480(15) \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$	[1]
Planck mass	$M_P = \sqrt{\hbar c G_N / c_P^2}$	$1.22980(14) \times 10^{19} \text{ GeV}/c^2 = 2.176434(24) \times 10^{-8} \text{ kg}$	[1]
Planck length	$l_P = \sqrt{\hbar G_N / c^3}$	$1.61625(18) \times 10^{-35} \text{ m}$	[1]
tropical year (equinox to equinox, 2020)	yr	$31566921.1 \text{ s} = 365.2421381 \text{ days}$	[1]
sidereal year (period of Earth around Sun relative to stars)	yr	$31558.4908 \text{ s} \approx \pi \times 10^7 \text{ s}$	[4]
mean sideric day (Earth rotation period relative to stars)	au	$23^{b}56^{m}04^{s}09.53$	[4]
astronomical unit	pc	140.67870700 m	exact [5]
parsec (1 au/l arc sec)	ly	$3.08567758149 \dots \times 10^{16} \text{ m} = 3.26156 \dots \text{ ly}$	exact [6]
light year (depreciated unit)	pc	$0.396601 \dots \text{ pc} = 0.946073 \dots \times 10^{16} \text{ m}$	[7]

New Heavy Bosons (W' , Z' , leptoquarks, etc.), Searches for

Additional W Bosons

W' with standard couplings

Mass $m > 6000 \text{ GeV}$, $\text{CL} = 95\%$ (pp direct search)

W_R (Right-handed W Boson)

Mass $m > 715 \text{ GeV}$, $\text{CL} = 90\%$ (electroweak fit)

Additional Z Bosons

Z'_{SM} with standard couplings

Mass $m > 5150 \text{ GeV}$, $\text{CL} = 95\%$ (pp direct search)

Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$ (with $g_L = g_R$)

Mass $m > 630 \text{ GeV}$, $\text{CL} = 95\%$ ($p\bar{p}$ direct search)

Mass $m > 1162 \text{ GeV}$, $\text{CL} = 95\%$ (electroweak fit)

Z_χ of $SO(10) \rightarrow SU(5) \times U(1)_\chi$ (with $g_\chi = e/\cos\theta_W$)

Mass $m > 4800 \text{ GeV}$, $\text{CL} = 95\%$ (pp direct search)

Z_ψ of $E_6 \rightarrow SO(10) \times U(1)_\psi$ (with $g_\psi = e/\cos\theta_W$)

Mass $m > 4560 \text{ GeV}$, $\text{CL} = 95\%$ (pp direct search)

Z_η of $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$ (with $g_\eta = e/\cos\theta_W$)

Mass $m > 3.900 \times 10^3 \text{ GeV}$, $\text{CL} = 95\%$ (pp direct search)

Scalar Leptoquarks

$m > 1800 \text{ GeV}$, $\text{CL} = 95\%$ (1st gen., pair prod., $B(eq)=1$)

$m > 1755 \text{ GeV}$, $\text{CL} = 95\%$ (1st gen., single prod., $B(eq)=1$)

$m > 1700 \text{ GeV}$, $\text{CL} = 95\%$ (2nd gen., pair prod., $B(\mu q)=1$)

$m > 660 \text{ GeV}$, $\text{CL} = 95\%$ (2nd gen., single prod., $B(\mu q)=1$)

$m > 1430 \text{ GeV}$, $\text{CL} = 95\%$ (3rd gen., pair prod., $B(\tau t)=1$)

$m > 740 \text{ GeV}$, $\text{CL} = 95\%$ (3rd gen., single prod., $B(\tau b)=1$)

(See the Particle Listings in the Full Review of Particle Physics for assumptions on leptoquark quantum numbers and branching fractions.)

Diquarks

Mass $m > 7200$ GeV, CL = 95% (E₆ diquark)

Axigluon

Mass $m > 6600$ GeV, CL = 95%

**Axions (A^0) and Other
Very Light Bosons, Searches for**

See the review on "Axions and other similar particles."

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N - 1)}$, where N is the number of measurements used in calculating the quantity.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b] ℓ indicates each type of lepton (e , μ , and τ), not sum over them.
- [c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, $p < 200$ MeV.
- [d] The Z -boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z -boson propagator.
- [e] This partial width takes into account Z decays into $\nu\bar{\nu}$ and any other possible undetected modes.
- [f] This ratio has not been corrected for the τ mass.
- [g] Here $A \equiv 2g_V g_A/(g_V^2 + g_A^2)$.
- [h] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06 (Physics Reports (Physics Letters C) **427** 257 (2006)).
- [i] Here ℓ indicates e or μ .
- [j] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [k] This value is updated using the product of (i) the $Z \rightarrow b\bar{b}$ fraction from this listing and (ii) the b -hadron fraction in an unbiased sample of weakly decaying b -hadrons produced in Z -decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).
- [l] See the Z Particle Listings in the Full Review of Particle Physics for the γ energy range used in this measurement.
- [n] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

**Lepton Family number (*LF*), Lepton number (*L*),
or Baryon number (*B*) violating modes**

L means lepton number violation (e.g. $\tau^- \rightarrow e^+ \pi^- \pi^-$). Following common usage, *LF* means lepton family violation *and not* lepton number violation (e.g. $\tau^- \rightarrow e^- \pi^+ \pi^-$). *B* means baryon number violation.

Heavy Charged Lepton Searches

L^\pm – charged lepton

Mass $m > 100.8$ GeV, CL = 95% [h] Decay to νW .

L^\pm – stable charged heavy lepton

Mass $m > 102.6$ GeV, CL = 95%

Neutrino Properties

See the note on “Neutrino properties listings” in the Particle Listings.

Mass $m < 1.1$ eV, CL = 90% (tritium decay)

Mean life/mass, $\tau/m > 300$ s/eV, CL = 90% (reactor)

Mean life/mass, $\tau/m > 7 \times 10^9$ s/eV (solar)

Mean life/mass, $\tau/m > 15.4$ s/eV, CL = 90% (accelerator)

Magnetic moment $\mu < 0.28 \times 10^{-10} \mu_B$, CL = 90% (solar + radiochemical)

Number of Neutrino Types

Number $N = 2.996 \pm 0.007$ (Standard Model fits to LEP-SLC data)

Number $N = 2.92 \pm 0.05$ ($S = 1.2$) (Direct measurement of invisible Z width)

Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review “Neutrino Masses, Mixing, and Oscillations.”

$$\sin^2(\theta_{12}) = 0.307 \pm 0.013$$

$$\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$$

$$\sin^2(\theta_{23}) = 0.539 \pm 0.022 \quad (S = 1.1) \quad (\text{Inverted order})$$

$$\sin^2(\theta_{23}) = 0.546 \pm 0.021 \quad (\text{Normal order})$$

$$\Delta m_{32}^2 = (-2.536 \pm 0.034) \times 10^{-3} \text{ eV}^2 \quad (\text{Inverted order})$$

$$\Delta m_{32}^2 = (2.453 \pm 0.033) \times 10^{-3} \text{ eV}^2 \quad (\text{Normal order})$$

$$\sin^2(\theta_{13}) = (2.20 \pm 0.07) \times 10^{-2}$$

$$\delta, CP \text{ violating phase} = 1.36^{+0.20}_{-0.16} \pi \text{ rad}$$

$$\langle \Delta m_{21}^2 - \Delta \bar{m}_{21}^2 \rangle < 1.1 \times 10^{-4} \text{ eV}^2, \text{ CL} = 99.7\%$$

$$\langle \Delta m_{32}^2 - \Delta \bar{m}_{32}^2 \rangle = (-0.12 \pm 0.25) \times 10^{-3} \text{ eV}^2$$

NOTES

In this Summary Table:

When a quantity has “(S = ...)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as $S = \sqrt{\chi^2/(N - 1)}$, where N is the number of measurements used in calculating the quantity.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] This is the best limit for the mode $e^- \rightarrow \nu\gamma$. The best limit for Nuclear de-excitation experiments is 6.4×10^{24} yr.
- [b] See the review on “Muon Decay Parameters” for definitions and details.
- [c] P_μ is the longitudinal polarization of the muon from pion decay. For $V-A$ coupling, $P_\mu = 1$ and $\rho = \delta = 3/4$.
- [d] This only includes events with energy of $e > 45$ MeV and energy of $\gamma > 40$ MeV. Since the $e^- \bar{\nu}_e \nu_\mu$ and $e^- \bar{\nu}_e \nu_\mu \gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [e] See the relevant Particle Listings in the Full *Review of Particle Physics* for the energy limits used in this measurement.
- [f] A test of additive vs. multiplicative lepton family number conservation.
- [g] Basis mode for the τ .
- [h] L^\pm mass limit depends on decay assumptions; see the Full Listings.

QUARKS

The u -, d -, and s -quark masses are the $\overline{\text{MS}}$ masses at the scale $\mu = 2 \text{ GeV}$. The c - and b -quark masses are the $\overline{\text{MS}}$ masses renormalized at the $\overline{\text{MS}}$ mass, i.e. $\overline{m} = \overline{m}(\mu = \overline{m})$. The t -quark mass is extracted from event kinematics (see the review “The Top Quark”).

u

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

$$m_u = 2.16^{+0.49}_{-0.26} \text{ MeV}$$

$$\text{Charge} = \frac{2}{3} e \quad I_z = +\frac{1}{2}$$

$$m_u/m_d = 0.474^{+0.056}_{-0.074}$$

d

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

$$m_d = 4.67^{+0.48}_{-0.17} \text{ MeV}$$

$$\text{Charge} = -\frac{1}{3} e \quad I_z = -\frac{1}{2}$$

$$m_s/m_d = 17-22$$

$$\overline{m} = (m_u + m_d)/2 = 3.45^{+0.35}_{-0.15} \text{ MeV}$$

s

$$I(J^P) = 0(\frac{1}{2}^+)$$

$$m_s = 93.4^{+8.6}_{-3.4} \text{ MeV} \quad \text{Charge} = -\frac{1}{3} e \quad \text{Strangeness} = -1$$

$$m_s / ((m_u + m_d)/2) = 27.33^{+0.67}_{-0.77}$$

c

$$I(J^P) = 0(\frac{1}{2}^+)$$

$$m_c = 1.27 \pm 0.02 \text{ GeV}$$

$$\text{Charge} = \frac{2}{3} e \quad \text{Charm} = +1$$

$$m_c/m_s = 11.76^{+0.05}_{-0.10}$$

$$m_b/m_c = 4.58 \pm 0.01$$

$$m_b - m_c = 3.45 \pm 0.05 \text{ GeV}$$

b

$$I(J^P) = 0(\frac{1}{2}^+)$$

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

[a] A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

[b] Based on published top mass measurements using data from Tevatron Run-I and Run-II and LHC at $\sqrt{s} = 7$ TeV. Including the most recent unpublished results from Tevatron Run-II, the Tevatron Electroweak Working Group reports a top mass of 173.2 ± 0.9 GeV. See the note "The Top Quark" in the Quark Particle Listings of this Review.

[c] This limit is for $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow W b)$.

[d] This limit is for $\Gamma(t \rightarrow Z q)/\Gamma(t \rightarrow W b)$.

\end{aligned}$$

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

CP-even fractions (labeled by the D^0 decay)

$$\begin{aligned} CP\text{-even fraction in } D^0 \rightarrow \pi^+ \pi^- \pi^0 \text{ decays} &= (97.3 \pm 1.7)\% \\ CP\text{-even fraction in } D^0 \rightarrow K^+ K^- \pi^0 \text{ decays} &= (73 \pm 6)\% \\ CP\text{-even fraction in } D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^- \text{ decays} &= (76.9 \pm 2.3)\% \\ CP\text{-even fraction in } D^0 \rightarrow K_S^0 \pi^+ \pi^- \pi^0 \text{ decays} &= (23.8 \pm 1.7)\% \\ CP\text{-even fraction in } D^0 \rightarrow K^+ K^- \pi^+ \pi^- \text{ decays} &= (75 \pm 4)\% \end{aligned}$$

CP-violation asymmetry difference

$$\Delta A_{CP} = A_{CP}(K^+ K^-) - A_{CP}(\pi^+ \pi^-) = (-0.154 \pm 0.029)\%$$

χ^2 tests of CP-violation (CPV) p-values

$$\begin{aligned} \text{Local CPV in } D^0, \overline{D^0} \rightarrow \pi^+ \pi^- \pi^0 &= 4.9\% \\ \text{Local CPV in } D^0, \overline{D^0} \rightarrow \pi^+ \pi^- \pi^+ \pi^- &= (0.6 \pm 0.2)\% \\ \text{Local CPV in } D^0, \overline{D^0} \rightarrow K_S^0 \pi^+ \pi^- &= 96\% \\ \text{Local CPV in } D^0, \overline{D^0} \rightarrow K^+ K^- \pi^0 &= 16.6\% \\ \text{Local CPV in } D^0, \overline{D^0} \rightarrow K^+ K^- \pi^+ \pi^- &= 9.1\% \end{aligned}$$

T-violation decay-rate asymmetry

$$A_T(K^+ K^- \pi^+ \pi^-) = (2.9 \pm 2.2) \times 10^{-3} \text{ [ii]}$$

$$A_{T\text{viol}}(K_S \pi^+ \pi^- \pi^0) \text{ in } D^0, \overline{D^0} \rightarrow K_S \pi^+ \pi^- \pi^0 = (-0.3^{+1.4}_{-1.6}) \times 10^{-3}$$

CPT-violation decay-rate asymmetry

$$A_{CPT}(K^\mp \pi^\pm) = 0.008 \pm 0.008$$

Form factors

$$\begin{aligned} r_V &\equiv V(0)/A_1(0) \text{ in } D^0 \rightarrow K^*(892)^- \ell^+ \nu_\ell = 1.46 \pm 0.07 \\ r_2 &\equiv A_2(0)/A_1(0) \text{ in } D^0 \rightarrow K^*(892)^- \ell^+ \nu_\ell = 0.68 \pm 0.06 \\ f_+(0) \text{ in } D^0 \rightarrow K^- \ell^+ \nu_\ell &= 0.736 \pm 0.004 \\ f_+(0)|V_{cs}| \text{ in } D^0 \rightarrow K^- \ell^+ \nu_\ell &= 0.7166 \pm 0.0030 \\ r_1 &\equiv a_1/a_0 \text{ in } D^0 \rightarrow K^- \ell^+ \nu_\ell = -2.40 \pm 0.16 \\ r_2 &\equiv a_2/a_0 \text{ in } D^0 \rightarrow K^- \ell^+ \nu_\ell = 5 \pm 4 \\ f_+(0) \text{ in } D^0 \rightarrow \pi^- \ell^+ \nu_\ell &= 0.637 \pm 0.009 \\ f_+(0)|V_{cd}| \text{ in } D^0 \rightarrow \pi^- \ell^+ \nu_\ell &= 0.1436 \pm 0.0026 \quad (S = 1.5) \\ r_1 &\equiv a_1/a_0 \text{ in } D^0 \rightarrow \pi^- \ell^+ \nu_\ell = -1.97 \pm 0.28 \quad (S = 1.4) \\ r_2 &\equiv a_2/a_0 \text{ in } D^0 \rightarrow \pi^- \ell^+ \nu_\ell = -0.2 \pm 2.2 \quad (S = 1.7) \end{aligned}$$

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \overline{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\overline{K}^0)$.

See Particle Listings for 2 decay modes that have been seen / not seen.

$D_{s2}^*(2573)$

$$I(J^P) = 0(2^+)$$

Mass $m = 2569.1 \pm 0.8$ MeV (S = 2.4)

$m_{D_{s2}^*(2573)} - m_{D^0} = 704 \pm 3.2$ MeV

Full width $\Gamma = 16.9 \pm 0.7$ MeV

$D_{s1}^*(2700)^\pm$

$$I(J^P) = 0(1^-)$$

Mass $m = 2714 \pm 5$ MeV (S = 1.5)

Full width $\Gamma = 122 \pm 10$ MeV

$D_{s3}^*(2860)^\pm$

$$I(J^P) = 0(3^-)$$

Mass $m = 2860 \pm 7$ MeV

Full width $\Gamma = 53 \pm 10$ MeV

BOTTOM MESONS ($B = \pm 1$)

$$B^+ = u\bar{b}, B^0 = d\bar{b}, \overline{B}{}^0 = \overline{d} b, B^- = \overline{u} b, \text{ similarly for } B^* \text{'s}$$

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: " B^\pm/B^0 Admixture" for $\Upsilon(4S)$ results and " $B^\pm/B^0/B_s^0/b$ -baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. $B^0-\overline{B}{}^0$ mixing data are found in the B^0 section, while $B_s^0-\overline{B}_s^0$ mixing data and $B-\overline{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP -violation data are found in the B^\pm , B^0 , and $B^\pm B^0$ Admixture sections. b -baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

- B^\pm
mass, mean life, CP violation, branching fractions
- B^0
mass, mean life, $B^0-\overline{B}{}^0$ mixing, CP violation,
branching fractions
- B^\pm/B^0 Admixtures
 CP violation, branching fractions
- $B^\pm/B^0/B_s^0/b$ -baryon Admixtures
mean life, production fractions, branching fractions
- B^*
mass
- $B_1(5721)^+$
mass
- $B_1(5721)^0$
mass
- $B_2^*(5747)^+$
mass
- $B_2^*(5747)^0$
mass
- $B_J^*(5970)^+$
mass
- $B_J^*(5970)^0$
mass
- B_s^0
mass, mean life, $B_s^0-\overline{B}_s^0$ mixing, CP violation,
branching fractions
- B_s^*
mass
- $B_{s1}(5830)^0$
mass
- $B_{s2}^*(5840)^0$
mass
- B_c^\pm
mass, mean life, branching fractions

At the end of Baryon Listings:

- Λ_b
mass, mean life, branching fractions
- $\Lambda_b(5912)^0$
mass, mean life
- $\Lambda_b(5920)^0$
mass, mean life

- Σ_b
mass
- Σ_b^*
mass
- Ξ_b^0, Ξ_b^-
mass, mean life, branching fractions
- $\Xi_b'(5935)^-$
mass
- $\Xi_b(5945)^0$
mass
- $\Xi_b^*(5955)^-$
mass
- Ω_b^-
mass, branching fractions
- b -baryon Admixture
mean life, branching fractions

B $^\pm$

$$I(J^P) = \frac{1}{2}(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^\pm} = 5279.34 \pm 0.12$ MeV

Mean life $\tau_{B^\pm} = (1.638 \pm 0.004) \times 10^{-12}$ s
 $c\tau = 491.1 \mu\text{m}$

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0 \bar{B}^0$ and 50% $B^+ B^-$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D , D_S , D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm X$, the values usually are multiplicities, not branching fractions. They can be greater than one.

\overline{B}^0 modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D , D_S , D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm X$, the values usually are multiplicities, not branching fractions. They can be greater than one.

$$A_{CP}(B \rightarrow K^* \ell^+ \ell^-) = -0.04 \pm 0.07$$

$$A_{CP}(B \rightarrow \eta \text{anything}) = -0.13^{+0.04}_{-0.05}$$

$$\Delta A_{CP}(X_s \gamma) = A_{CP}(B^\pm \rightarrow X_s \gamma) - A_{CP}(B^0 \rightarrow X_s \gamma) = 0.041 \pm 0.023$$

$$\overline{A}_{CP}(B \rightarrow X_s \gamma) = (A_{CP}(B^+ \rightarrow X_s \gamma) + A_{CP}(B^0 \rightarrow X_s \gamma))/2 = 0.009 \pm 0.012$$

$$\Delta A_{CP}(B \rightarrow K^*\gamma) = A_{CP}(B^+ \rightarrow K^{*+}\gamma) - A_{CP}(B^0 \rightarrow K^{*0}\gamma) = 0.024 \pm 0.028$$

$$\overline{A}_{CP}(B \rightarrow K^*\gamma) = (A_{CP}(B^+ \rightarrow K^{*+}\gamma) + A_{CP}(B^0 \rightarrow K^{*0}\gamma))/2 = -0.001 \pm 0.014$$

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{anything}$, the treatment of multiple D 's in the final state must be defined. One possibility would be to count the number of events with one-or-more D 's and divide by the total number of B 's. Another possibility would be to count the total number of D 's and divide by the total number of B 's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

\overline{B} modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

$B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LHC, LEP, Tevatron, $Spp\bar{S}$).

$$\text{Mean life } \tau = (1.5672 \pm 0.0029) \times 10^{-12} \text{ s}$$

$$\text{Mean life } \tau = (1.72 \pm 0.10) \times 10^{-12} \text{ s} \quad \text{Charged } b\text{-hadron admixture}$$

$$\text{Mean life } \tau = (1.58 \pm 0.14) \times 10^{-12} \text{ s} \quad \text{Neutral } b\text{-hadron admixture}$$

$$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$$

$$|\Delta\tau_b|/\tau_{b\bar{b}} = -0.001 \pm 0.014$$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LHC, LEP, Tevatron, $S\bar{p}\bar{D}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a \bar{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

\bar{b} DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
---	--------------------------------	-----------------------------------	----------------

PRODUCTION FRACTIONS

The production fractions for weakly decaying b -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFLAV) as described in the note “ B - \bar{B}^0 Mixing” in the B^0 Particle Listings. We no longer provide world averages of the b -hadron production fractions, where results from LEP, Tevatron and LHC are averaged together; indeed the available data (from CDF and LHCb) shows that the fractions depend on the kinematics (in particular the p_T) of the produced b hadron. Hence we would like to list the fractions in Z decays instead, which are well-defined physics observables. The production fractions in $p\bar{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0) \\ B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The correlation coefficients between production fractions are also reported:

$$\text{cor}(B_s^0, b\text{-baryon}) = 0.064 \\ \text{cor}(B_s^0, B^\pm = B^0) = -0.633 \\ \text{cor}(b\text{-baryon}, B^\pm = B^0) = -0.813.$$

The notation for production fractions varies in the literature (f_d , d_{B^0} , $f(b \rightarrow \bar{B}^0)$, $\text{Br}(b \rightarrow \bar{B}^0)$). We use our own branching fraction notation here, $B(\bar{b} \rightarrow B^0)$.

Note these production fractions are b -hadronization fractions, not the conventional branching fractions of b -quark to a B -hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

These branching fractions all scale with $B(\bar{B} \rightarrow B_s^0)$.

The branching fraction $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{anything})$ is not a pure measurement since the measured product branching fraction $B(\bar{B} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{anything})$ was used to determine $B(\bar{B} \rightarrow B_s^0)$, as described in the note on “ B^0 - \bar{B}^0 Mixing”

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] See the review on "Form Factors for Radiative Pion and Kaon Decays" for definitions and details.

- [b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$.
- [c] See the π^\pm Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement; low-energy γ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order 10^{-13} , but they are model dependent and for the summary value we use the best laboratory limit, which includes any final state of invisible particles.
- [f] Forbidden by angular momentum conservation.
- [g] C parity forbids this to occur as a single-photon process.
- [h] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+\mu^-) = \Gamma(\rho^0 \rightarrow e^+e^-) \times 0.99785$.
- [i] Our estimate. See the Particle Listings for details.
- [j] See the “Note on $a_1(1260)$ ” in the $a_1(1260)$ Particle Listings in PDG 06, Journal of Physics **G33** 1 (2006).
- [k] See also the $\omega(1650)$.
- [l] See also the $\omega(1420)$.
- [n] See the note in the K^\pm Particle Listings in the Full Review of Particle Physics.
- [o] Neglecting photon channels. See, e.g., A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).
- [p] The definition of the slope parameters of the $K \rightarrow 3\pi$ Dalitz plot is as follows (see also “Note on Dalitz Plot Parameters for $K \rightarrow 3\pi$ Decays” in the K^\pm Particle Listings in the Full Review of Particle Physics):
- $$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \dots$$
- [q] For more details and definitions of parameters see Particle Listings in the Full Review of Particle Physics.
- [r] See the K^\pm Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.
- [s] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [t] Structure-dependent part.
- [u] Direct-emission branching fraction.
- [v] Violates angular-momentum conservation.
- [x] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K_L^0} - m_{K_S^0}|$, and $\tau_{K_S^0}$, as described in the introduction to “Tests of Conservation Laws.”
- [y] The CP -violation parameters are defined as follows (see also “Note on CP Violation in $K_S \rightarrow 3\pi$ ” and “Note on CP Violation in K_L^0 Decay” in the Particle Listings in the Full Review of Particle Physics):
- $$\eta_{+-} = |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \rightarrow \pi^+\pi^-)}{A(K_S^0 \rightarrow \pi^+\pi^-)} = \epsilon + \epsilon'$$
- $$\eta_{00} = |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \rightarrow \pi^0\pi^0)}{A(K_S^0 \rightarrow \pi^0\pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)},$$

$$\text{Im}(\eta_{+-0})^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^+ \pi^- \pi^0) \text{CP viol.}}{\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)},$$

$$\text{Im}(\eta_{000})^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)}{\Gamma(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0)}.$$

where for the last two relations *CPT* is assumed valid, i.e., $\text{Re}(\eta_{+-0}) \simeq 0$ and $\text{Re}(\eta_{000}) \simeq 0$.

- [z] See the K_S^0 Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.
- [aa] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [bb] $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$ to a very good approximation provided the phases satisfy *CPT* invariance.
- [cc] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \rightarrow \pi^+ \pi^- \gamma$ (DE).
- [dd] See the K_L^0 Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.
- [ee] Allowed by higher-order electroweak interactions.
- [ff] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.
- [gg] See our minireview under the $K_2(1770)$ in the 2004 edition of this Review.
- [hh] This result applies to $Z^0 \rightarrow c\bar{c}$ decays only. Here ℓ^+ is an average (not a sum) of e^+ and μ^+ decays.
- [ii] See the Particle Listings for the (complicated) definition of this quantity.
- [jj] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings in the Full Review of Particle Physics.
- [kk] These subfractions of the $K^- 2\pi^+$ mode are uncertain: see the Particle Listings.
- [ll] Submodes of the $D^+ \rightarrow K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [nn] The unseen decay modes of the resonances are included.
- [oo] This is *not* a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.
- [pp] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.
- [qq] In the 2010 Review, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.
- [rr] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.

- [ss] This is the sum of our $K^- 2\pi^+ \pi^-$, $K^- 2\pi^+ \pi^- \pi^0$, $\overline{K}^0 2\pi^+ 2\pi^-$, $K^+ 2K^- \pi^+$, $2\pi^+ 2\pi^-$, $2\pi^+ 2\pi^- \pi^0$, $K^+ K^- \pi^+ \pi^-$, and $K^+ K^- \pi^+ \pi^- \pi^0$, branching fractions.
- [tt] This is the sum of our $K^- 3\pi^+ 2\pi^-$ and $3\pi^+ 3\pi^-$ branching fractions.
- [uu] The branching fractions for the $K^- e^- \nu_e$, $K^*(892)^- e^+ \nu_e$, $\pi^- e^+ \nu_e$, and $\rho^- e^+ \nu_e$ modes add up to $6.17 \pm 0.17\%$.
- [vv] This is a doubly Cabibbo-suppressed mode.
- [xx] Submodes of the $D^0 \rightarrow K_S^0 \pi^+ \pi^- \pi^0$ mode with a K^* and/or ρ were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [yy] This branching fraction includes all the decay modes of the resonance in the final state.
- [zz] This limit is for either D^0 or \overline{D}^0 to $p e^-$.
- [aaa] This limit is for either D^0 or \overline{D}^0 to $\overline{p} e^+$.
- [bbb] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non- τ) e^+ exclusive fractions — an $e^+ \nu_e$ with an η , η' , ϕ , K^0 , or K^{*0} — is $5.99 \pm 0.31\%$.
- [ccc] This fraction includes η from η' decays.
- [ddd] The sum of our exclusive η' fractions — $\eta' e^+ \nu_e$, $\eta' \mu^+ \nu_\mu$, $\eta' \pi^+$, $\eta' \rho^+$, and $\eta' K^+$ — is $11.8 \pm 1.6\%$.
- [eee] This branching fraction includes all the decay modes of the final-state resonance.
- [fff] A test for $u\overline{u}$ or $d\overline{d}$ content in the D_s^+ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and $\omega - \phi$ mixing is an unlikely explanation for any fraction above about 2×10^{-4} .
- [ggg] We decouple the $D_s^+ \rightarrow \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi \pi^+$, $\phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.
- [hhh] This is the average of a model-independent and a K -matrix parametrization of the $\pi^+ \pi^-$ S -wave and is a sum over several f_0 mesons.
- [iii] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [jjj] An $CP(\pm 1)$ indicates the $CP=+1$ and $CP=-1$ eigenstates of the D^0 - \overline{D}^0 system.
- [kkk] D denotes D^0 or \overline{D}^0 .
- [lll] D_{CP+}^{*0} decays into $D^0 \pi^0$ with the D^0 reconstructed in CP -even eigenstates $K^+ K^-$ and $\pi^+ \pi^-$.
- [nnn] \overline{D}^{**} represents an excited state with mass $2.2 < M < 2.8$ GeV/c².
- [ooo] $\chi_{c1}(3872)^+$ is a hypothetical charged partner of the $\chi_{c1}(3872)$.
- [ppp] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.
- [qqq] $(\overline{\Lambda}_c^- \rho)_s$ denotes a low-mass enhancement near 3.35 GeV/c².
- [rrr] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

- [sss] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.
- [ttt] This decay refers to the coherent sum of resonant and nonresonant $J^P = 0^+$ $K\pi$ components with $1.60 < m_{K\pi} < 2.15 \text{ GeV}/c^2$.
- [uuu] $X(214)$ is a hypothetical particle of mass $214 \text{ MeV}/c^2$ reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005).
- [vvv] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.
- [xxx] Here S and P are the hypothetical scalar and pseudoscalar particles with masses of $2.5 \text{ GeV}/c^2$ and $214.3 \text{ MeV}/c^2$, respectively.
- [yyy] These values are model dependent.
- [zzz] Here “anything” means at least one particle observed.
- [aaaa] This is a $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell)$ value.
- [bbaa] D^{**} stands for the sum of the $D(1^1P_1)$, $D(1^3P_0)$, $D(1^3P_1)$, $D(1^3P_2)$, $D(2^1S_0)$, and $D(2^1S_1)$ resonances.
- [ccaa] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.
- [ddaa] $X(3915)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.
- [eeaa] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [ffaa] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P -wave) states.
- [ggaa] Not a pure measurement. See note at head of B_s^0 Decay Modes.
- [hhaa] For $E_\gamma > 100 \text{ MeV}$.
- [iiaa] $\Theta(1540)$ is a hypothetical pentaquark state of $1.54 \text{ GeV}/c^2$ mass and a width of less than $25 \text{ MeV}/c^2$.
- [jjaa] Includes $p\bar{p}\pi^+\pi^-\gamma$ and excludes $p\bar{p}\eta$, $p\bar{p}\omega$, $p\bar{p}\eta'$.
- [kkaa] For a narrow state A with mass less than 960 MeV .
- [lla] For a narrow scalar or pseudoscalar A^0 with mass $0.21\text{--}3.0 \text{ GeV}$.
- [nnaa] For a dark photon U with mass between 100 and 2100 MeV .
- [ooaa] For a narrow resonance in the range $2.2 < M(X) < 2.8 \text{ GeV}$.
- [ppaa] J/PC known by production in e^+e^- via single photon annihilation.
 $/G$ is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.
- [qqaa] $2m_\tau < M(\tau^+\tau^-) < 9.2 \text{ GeV}$
- [rraa] $2 \text{ GeV} < m_{K^+K^-} < 3 \text{ GeV}$
- [ssaa] X = scalar with $m < 8.0 \text{ GeV}$
- [ttaa] $X\overline{X}$ = vectors with $m < 3.1 \text{ GeV}$
- [uuaa] X and \overline{X} = zero spin with $m < 4.5 \text{ GeV}$
- [vvaa] $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [xxaa] $201 \text{ MeV} < M(\mu^+\mu^-) < 3565 \text{ MeV}$
- [yyaa] $0.5 \text{ GeV} < m_X < 9.0 \text{ GeV}$, where m_X is the invariant mass of the hadronic final state.
- [zzaa] Spectroscopic labeling for these states is theoretical, pending experimental information.
- [aab] $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [bbb] $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [ccb] For $m_{\tau^+\tau^-}$ in the ranges $4.03\text{--}9.52$ and $9.61\text{--}10.10 \text{ GeV}$.

See Particle Listings for 1 decay modes that have been seen / not seen.

$\Lambda_c(2595)^+$

$$I(J^P) = 0(\frac{1}{2}^-)$$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant. This assumes that $J^P = 1/2^+$ for the $\Sigma_c(2455)$.

Mass $m = 2592.25 \pm 0.28$ MeV

$m - m_{\Lambda_c^+} = 305.79 \pm 0.24$ MeV

Full width $\Gamma = 2.6 \pm 0.6$ MeV

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

 $\Lambda_c(2595)^+$ DECAY MODES

$$\text{Fraction } (\Gamma_i/\Gamma)$$

$$p \text{ (MeV/c)}$$

$\Lambda_c^+\pi^+\pi^-$	[s] —	117
$\Sigma_c(2455)^{++}\pi^-$	$24 \pm 7\%$	3
$\Sigma_c(2455)^0\pi^+$	$24 \pm 7\%$	3
$\Lambda_c^+\pi^+\pi^-$ 3-body	$18 \pm 10\%$	117

See Particle Listings for 2 decay modes that have been seen / not seen.

 $\Lambda_c(2625)^+$

$$I(J^P) = 0(\frac{3}{2}^-)$$

J^P has not been measured; $\frac{3}{2}^-$ is the quark-model prediction.

Mass $m = 2628.11 \pm 0.19$ MeV (S = 1.1)

$m - m_{\Lambda_c^+} = 341.65 \pm 0.13$ MeV (S = 1.1)

Full width $\Gamma < 0.97$ MeV, CL = 90%

$\Lambda_c^+\pi\pi$ and its submode $\Sigma(2455)\pi$ are the only strong decays allowed to an excited Λ_c^+ having this mass.

 $\Lambda_c(2625)^+$ DECAY MODES

$$\text{Fraction } (\Gamma_i/\Gamma)$$

$$p \text{ (MeV/c)}$$

$\Lambda_c^+\pi^+\pi^-$	$\approx 67\%$	184

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow N(1520)^0 K^*(892)^0) = (5.5 \pm 2.5) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow \Lambda(1520)\rho(770)^0) = (1 \pm 6) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow \Delta(1232)^{++}K^-\pi^-) = (4.4 \pm 2.7) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow pK_1(1410)^-) = (5 \pm 4) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow pK^-\pi^+\pi^-) = (-7 \pm 5) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow pK^-\pi^+K^-) = (0.2 \pm 1.9) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow \Lambda(1520)\phi(1020)) = (4 \pm 6) \times 10^{-2}$$

$$\Delta A_{CP}(\Lambda_b^0 \rightarrow (pK^-)_{highmass}\phi(1020)) = (-0.7 \pm 3.4) \times 10^{-2}$$

$$\begin{aligned}\Delta A_{CP}(\Lambda_b^0 \rightarrow (p K^- K^+ K^-)_{LBM}) &= (2.7 \pm 2.4) \times 10^{-2} \\ A_{FB}^\ell(\mu\mu) \text{ in } \Lambda_b \rightarrow \Lambda\mu^+\mu^- &= -0.39 \pm 0.04 \\ \Delta(A_{FB}^\ell(\mu\mu)) \text{ in } \Lambda_b \rightarrow \Lambda\mu^+\mu^- &= -0.05 \pm 0.09 \\ A_{FB}^h(p\pi) \text{ in } \Lambda_b \rightarrow \Lambda(p\pi)\mu^+\mu^- &= -0.30 \pm 0.05 \\ A_{FB}^{th} \text{ in } \Lambda_b \rightarrow \Lambda\mu^+\mu^- &= 0.25 \pm 0.04\end{aligned}$$

The branching fractions $B(b\text{-baryon} \rightarrow \Lambda\ell^-\bar{\nu}_\ell \text{anything})$ and $B(\Lambda_b^0 \rightarrow \Lambda_c^+\ell^-\bar{\nu}_\ell \text{anything})$ are not pure measurements because the underlying measured products of these with $B(b \rightarrow b\text{-baryon})$ were used to determine $B(b \rightarrow b\text{-baryon})$, as described in the note "Production and Decay of b -Flavored Hadrons."

For inclusive branching fractions, e.g., $\Lambda_b \rightarrow \bar{\Lambda}_c$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

b-baryon ADMIXTURE ($\Lambda_b, \Xi_b, \Omega_b$)

These branching fractions are actually an average over weakly decaying b -baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the b -baryon production fraction $B(b \rightarrow b\text{-baryon})$.

The branching fractions $B(b\text{-baryon} \rightarrow \Lambda \ell^- \bar{\nu}_\ell \text{anything})$ and $B(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell \text{anything})$ are not pure measurements because the underlying measured products of these with $B(b \rightarrow b\text{-baryon})$ were used to determine $B(b \rightarrow b\text{-baryon})$, as described in the note "Production and Decay of b -Flavored Hadrons."

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

b-baryon ADMIXTURE DECAY MODES (Λ_b, Ξ_b, Ω_b)	Fraction (Γ_i/Γ)	Scale factor	p (MeV/c)
$p\mu^-\bar{\nu}$ anything	(5.8 \pm 2.3) %		-

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together.

When a quantity has "($S = \dots$)" to its right, the error on the quantity has been enlarged by the "scale factor" S , defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p .

- [a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.494061(21) MeV, is less well known than are the masses in u.
- [b] The $|m_p - m_{\bar{p}}|/m_p$ and $|q_p + q_{\bar{p}}|/e$ are not independent, and both use the more precise measurement of $|q_{\bar{p}}/m_{\bar{p}}|/(q_p/m_p)$.
- [c] The limit is from neutrality-of-matter experiments; it assumes $q_n = q_p + q_e$. See also the charge of the neutron.
- [d] The μp and $e p$ values for the charge radius are much too different to average them. The disagreement is not yet understood.
- [e] There is a lot of disagreement about the value of the proton magnetic charge radius. See the Listings.
- [f] The first limit is for $p \rightarrow$ anything or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \bar{p} 's is $\tau_{\bar{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\bar{p}}/B(\bar{p} \rightarrow e^- \gamma) > 7 \times 10^5$ yr.
- [g] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [h] Lee and Yang in 1956 proposed the existence of a mirror world in an attempt to restore global parity symmetry—thus a search for oscillations

between the two worlds. Oscillations between the worlds would be maximal when the magnetic fields B and B' were equal. The limit for any B' in the range 0 to $12.5 \mu\text{T}$ is $>12 \text{ s}$ (95% CL).

[i] The parameters g_A , g_V , and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V + g_A\gamma_5) + i(g_{WM}/m_{B_i}) \sigma_{\lambda\nu} q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}$. See the “Note on Baryon Decay Parameters” in the neutron Particle Listings in the Full Review of Particle Physics.

[j] Time-reversal invariance requires this to be 0° or 180° .

[k] This coefficient is zero if time invariance is not violated.

[l] This limit is for γ energies between 0.4 and 782 keV.

[n] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-\alpha^2} \cos\phi, \quad \tan\Delta = -\frac{1}{\alpha} \sqrt{1-\alpha^2} \sin\phi.$$

See the “Note on Baryon Decay Parameters” in the neutron Particle Listings in the Full Review of Particle Physics.

[o] See Particle Listings in the Full Review of Particle Physics for the pion momentum range used in this measurement.

[p] Our estimate. See the Particle Listings for details.

[q] A theoretical value using QED.

[r] This branching fraction includes all the decay modes of the final-state resonance.

[s] See AALTONEN 11H, Fig. 8, for the calculated ratio of $\Lambda_c^+ \pi^0 \pi^0$ and $\Lambda_c^+ \pi^+ \pi^-$ partial widths as a function of the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass difference. At our value of the mass difference, the ratio is about 4.

[t] P_c^+ is a pentaquark-charmonium state.

[u] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.

[v] Here h^- means π^- or K^- .

SEARCHES not in other sections

Magnetic Monopole Searches

The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$$< 1.4 \times 10^{-16} \text{ cm}^{-2}\text{sr}^{-1}\text{s}^{-1} \quad \text{for } 1.1 \times 10^{-4} < \beta < 1$$

Supersymmetric Particle Searches

All supersymmetric mass bounds here are model dependent.

The limits assume:

- 1) $\tilde{\chi}_1^0$ is the lightest supersymmetric particle; 2) R -parity is conserved, unless stated otherwise;

See the Particle Listings in the Full *Review of Particle Physics* for a Note giving details of supersymmetry.

$\tilde{\chi}_i^0$ — neutralinos (mixtures of $\tilde{\gamma}$, \tilde{Z}^0 , and \tilde{H}_i^0)

Mass $m_{\tilde{\chi}_1^0} > 0$ GeV, CL = 95%

[general MSSM, non-universal gaugino masses]

Mass $m_{\tilde{\chi}_1^0} > 46$ GeV, CL = 95%

[all $\tan\beta$, all m_0 , all $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$]

Mass $m_{\tilde{\chi}_2^0} > 62.4$ GeV, CL = 95%

[$1 < \tan\beta < 40$, all m_0 , all $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$]

Mass $m_{\tilde{\chi}_3^0} > 99.9$ GeV, CL = 95%

[$1 < \tan\beta < 40$, all m_0 , all $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$]

Mass $m_{\tilde{\chi}_4^0} > 116$ GeV, CL = 95%

[$1 < \tan\beta < 40$, all m_0 , all $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$]

$\tilde{\chi}_i^\pm$ — charginos (mixtures of \tilde{W}^\pm and \tilde{H}_i^\pm)

Mass $m_{\tilde{\chi}_1^\pm} > 94$ GeV, CL = 95%

[$\tan\beta < 40$, $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 3$ GeV, all m_0]

Mass $m_{\tilde{\chi}_1^\pm} > 1000$ GeV, CL = 95%

[$2\ell + E_T$, Tchi1chi1C, $m_{\tilde{\chi}_1^0} = 0$ GeV]

$\tilde{\chi}^\pm$ — long-lived chargino

Mass $m_{\tilde{\chi}^\pm} > 620$ GeV, CL = 95% [stable $\tilde{\chi}^\pm$]

$\tilde{\nu}$ — sneutrino

Mass $m > 41$ GeV, CL = 95% [model independent]

Mass $m > 94$ GeV, CL = 95%

[CMSSM, $1 \leq \tan\beta \leq 40$, $m_{\tilde{e}_R} - m_{\tilde{\chi}_1^0} > 10$ GeV]

Mass $m > 3400$ GeV, CL = 95% [R-Parity Violating]

[$\tilde{\nu}_\tau \rightarrow e\mu$, $\lambda_{312} = \lambda_{321} = 0.07$, $\lambda'_{311} = 0.11$]

\tilde{e} — scalar electron (selectron)

Mass $m > 107$ GeV, CL = 95% [all $m_{\tilde{e}_L} - m_{\tilde{\chi}_1^0}$]

Mass $m > 700$ GeV, CL = 95%

[$2\ell + \cancel{E}_T$, $m_{\tilde{\ell}_R} = m_{\tilde{\ell}_L}$ and $\tilde{\ell} = \tilde{e}$, $\tilde{\mu}$, $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 250$ GeV, CL = 95%

[$\ell^\pm \ell^\mp + \cancel{E}_T$, \tilde{e}_R , $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 410$ GeV, CL = 95% [R-Parity Violating]

[$\geq 4\ell^\pm$, $\tilde{\ell} \rightarrow l\tilde{\chi}_1^0$, $\tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$]

$\tilde{\mu}$ — scalar muon (smuon)

Mass $m > 700$ GeV, CL = 95%

[$2\ell + \cancel{E}_T$, $m_{\tilde{\ell}_R} = m_{\tilde{\ell}_L}$ and $\tilde{\ell} = \tilde{e}$, $\tilde{\mu}$, $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 210$, CL = 95%

[$\ell^\pm \ell^\mp + \cancel{E}_T$, $\tilde{\mu}_R$, $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 94$ GeV, CL = 95%

[CMSSM, $1 \leq \tan\beta \leq 40$, $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10$ GeV]

Mass $m > 410$ GeV, CL = 95% [R-Parity Violating]

[$\geq 4\ell^\pm$, $\tilde{\ell} \rightarrow l\tilde{\chi}_1^0$, $\tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$]

$\tilde{\tau}$ — scalar tau (stau)

Mass $m > 81.9$ GeV, CL = 95%

[$m_{\tilde{\tau}_R} - m_{\tilde{\chi}_1^0} > 15$ GeV, all θ_τ , $B(\tilde{\tau} \rightarrow \tau \tilde{\chi}_1^0) = 100\%$]

Mass $m > 90$ GeV, CL = 95%

[RPV, $\tilde{\tau}_R$, indirect, $\Delta m > 5$ GeV]

Mass $m > 286$ GeV, CL = 95% [long-lived $\tilde{\tau}$]

\tilde{q} — squarks of the first two quark generations

Mass $m > 1.220 \times 10^3$ GeV, CL = 95%

[b -jets + \cancel{E}_T , Tsqk1, 1 non-degenerate \tilde{q} , $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 1.600 \times 10^3$ GeV, CL = 95% [R-Parity Violating]

[$\tilde{q} \rightarrow q\tilde{\chi}_1^0$, $\tilde{\chi}_1^0 \rightarrow \ell\ell\nu$, $\lambda_{121}, \lambda_{122} \neq 0$, $m_{\tilde{g}} = 2400$ GeV]

\tilde{q} — long-lived squark

Mass $m > 1340$, CL = 95% [\tilde{t} R-hadrons]

Mass $m > 1250$, CL = 95% [\tilde{b} R-hadrons]

\tilde{b} — scalar bottom (sbottom)

Mass $m > 1.270 \times 10^3$ GeV, CL = 95%

[b -jets + \cancel{E}_T , Tstop1, $m_{\tilde{\chi}_1^0} = 0$ GeV]

Mass $m > 307$ GeV, CL = 95% [R-Parity Violating]

[$\tilde{b} \rightarrow t d$ or $t s$, λ''_{332} or λ''_{331} coupling]

\tilde{t} — scalar top (stop)

Mass $m > 1.310 \times 10^3$ GeV, CL = 95%

[b -jets + \cancel{E}_T , Tstop1, $m_{\tilde{\chi}_1^0} < 300$ GeV]

Mass $m > 1100$ GeV, CL = 95% [R-Parity Violating]

[$\tilde{t} \rightarrow b e$, Tstop2RPV, prompt]

\tilde{g} — gluino

Mass $m > 2.300 \times 10^3$ GeV, CL = 95%

[$\text{jets} + \cancel{E}_T$, Tglu1A, $m_{\tilde{\chi}_1^0} < 200$ GeV]

Mass $m > 2.260 \times 10^3$ GeV, CL = 95% [R-Parity Violating]

[$\geq 4\ell$, $\lambda_{12k} \neq 0$, $m_{\tilde{\chi}_1^0} > 1000$ GeV]

Technicolor

The limits for technicolor (and top-color) particles are quite varied depending on assumptions. See the Technicolor section of the full *Review* (the data listings).

Quark and Lepton Compositeness, Searches for

Scale Limits Λ for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^\pm$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(e e e e)$	> 8.3 TeV, CL = 95%
$\Lambda_{LL}^-(e e e e)$	> 10.3 TeV, CL = 95%

$\Lambda_{LL}^+(\nu\nu qq)$	> 5.0 TeV, CL = 95%
$\Lambda_{LL}^-(\nu\nu qq)$	> 5.4 TeV, CL = 95%

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ -dependent limits assume chiral coupling.

$e^{*\pm}$ — excited electron

Mass $m >$ 103.2 GeV, CL = 95% (from e^*e^*)
Mass $m >$ 5.600×10^3 GeV, CL = 95% (from $e e^*$)
Mass $m >$ 356 GeV, CL = 95% (if $\lambda_\gamma = 1$)

$\mu^{*\pm}$ — excited muon

Mass $m >$ 103.2 GeV, CL = 95% (from $\mu^*\mu^*$)
Mass $m >$ 5.700×10^3 GeV, CL = 95% (from $\mu\mu^*$)

$\tau^{*\pm}$ — excited tau

Mass $m >$ 103.2 GeV, CL = 95% (from $\tau^*\tau^*$)
Mass $m >$ 2.500×10^3 GeV, CL = 95% (from $\tau\tau^*$)

ν^* — excited neutrino

Mass $m >$ 1.600×10^3 GeV, CL = 95% (from $\nu^*\nu^*$)
Mass $m >$ 213 GeV, CL = 95% (from ν^*X)

q^* — excited quark

Mass $m >$ 338 GeV, CL = 95% (from q^*q^*)
Mass $m >$ 6700 GeV, CL = 95% (from q^*X)

Color Sextet and Octet Particles

Color Sextet Quarks (q_6)

Mass $m >$ 84 GeV, CL = 95% (Stable q_6)

Color Octet Charged Leptons (ℓ_8)

Mass $m >$ 86 GeV, CL = 95% (Stable ℓ_8)
--

Color Octet Neutrinos (ν_8)

Mass $m >$ 110 GeV, CL = 90% ($\nu_8 \rightarrow \nu g$)
--

Extra Dimensions

Please refer to the Extra Dimensions section of the full *Review* for a discussion of the model-dependence of these bounds, and further constraints.

**Constraints on the radius of the extra dimensions,
for the case of two-flat dimensions of equal radii**

(direct tests of Newton's law)

$R < 3.8 \text{ }\mu\text{m}$, CL = 95% ($pp \rightarrow j G$)

$R < 0.16\text{--}916 \text{ nm}$ (astrophysics; limits depend on technique and assumptions)

Constraints on the fundamental gravity scale

$M_{TT} > 9.02 \text{ TeV}$, CL = 95% ($pp \rightarrow \text{dijet, angular distribution}$)

$M_c > 4.16 \text{ TeV}$, CL = 95% ($pp \rightarrow \ell\bar{\ell}$)

Constraints on the Kaluza-Klein graviton in warped extra dimensions

$M_G > 4.78 \text{ TeV}$, CL = 95% ($pp \rightarrow e^+e^-, \mu^+\mu^-$)

Constraints on the Kaluza-Klein gluon in warped extra dimensions

$M_{g_{KK}} > 3.8 \text{ TeV}$, CL = 95% ($g_{KK} \rightarrow t\bar{t}$)

WIMP and Dark Matter Searches

No confirmed evidence found for galactic WIMPs from the GeV to the TeV mass scales and down to $1 \times 10^{-10} \text{ pb}$ spin independent cross section at $M = 100 \text{ GeV}$.

Tests of Conservation Laws

Revised May 2022 by A. Pich (IFIC, Valencia) and M. Ramsey-Musolf (Tsung-Dao Lee Inst.; SJTU; U. Massachusetts).

The following text discusses the best limits among those included in the full Review, where more complete details can be found. Unless otherwise specified, all limits quoted here are given at a C.L. of 90%.

DISCRETE SPACE-TIME SYMMETRIES

Charge conjugation (C), parity (P) and time reversal (T) are empirically found to be symmetries of the electromagnetic (QED) and strong (QCD) interactions, but they are violated by the weak forces. The product of the three discrete symmetries, CPT , is an exact symmetry of any local and Lorentz-invariant quantum field theory with a positive-definite Hermitian Hamiltonian that preserves micro-causality.

1 Violations of CP and T

The first evidence of CP non-invariance in particle physics was the observation in 1964 of $K_L^0 \rightarrow \pi^+ \pi^-$ decays. The non-zero ratio $|\eta_{+-}| \equiv |\mathcal{M}(K_L^0 \rightarrow \pi^+ \pi^-)/\mathcal{M}(K_S^0 \rightarrow \pi^+ \pi^-)| = (2.232 \pm 0.011) \times 10^{-3}$ could be explained as a $K^0 - \bar{K}^0$ mixing effect ($\eta_{+-} = \epsilon$), which would imply an identical ratio $\eta_{00} \equiv \mathcal{M}(K_L^0 \rightarrow \pi^0 \pi^0)/\mathcal{M}(K_S^0 \rightarrow \pi^0 \pi^0)$ in the neutral decay mode and successfully predicts the observed CP -violating semileptonic asymmetry $[\Gamma(K_L^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_L^0 \rightarrow \pi^+ e^- \bar{\nu}_e)]/\text{[sum]} = (3.34 \pm 0.07) \times 10^{-3}$. A tiny difference between η_{+-} and η_{00} was reported for the first time in 1988 by the CERN NA31 experiment, and later established at the 7.2σ level with the full data samples from the NA31, E731, NA48 and KTeV experiments: $\text{Re}(\epsilon'/\epsilon) = \frac{1}{3} (1 - |\eta_{00}/\eta_{+-}|) = (1.66 \pm 0.23) \times 10^{-3}$. This important measurement confirmed that CP violation is associated with a $\Delta S = 1$ transition, as predicted by the CKM mechanism. The Standard Model (SM) prediction, $\text{Re}(\epsilon'/\epsilon) = (1.4 \pm 0.5) \times 10^{-3}$, is in good agreement with the measured ratio, although the theoretical uncertainty is unfortunately large.

Much larger CP asymmetries have been later measured in B meson decays, many of them involving the interference between $B^0 - \bar{B}^0$ mixing and the decay amplitude. They provide many successful tests of the CKM unitarity structure, validating the SM mechanism of CP violation (see the review on CP violation in the quark sector). Prominent signals of direct CP violation have been also clearly established in several B^\pm , B_d^0 and B_s^0 decays, and, very recently, in charm decays.

While CP violation implies a breaking of time-reversal symmetry, direct tests of T violation are much more difficult. The CPLEAR experiment observed longtime ago a non-zero difference between the oscillation probabilities of $K^0 \rightarrow \bar{K}^0$ and $\bar{K}^0 \rightarrow K^0$. More recently, the exchange of initial and final states has been made possible in B decays, taking advantage of the entanglement of the two daughter mesons produced in the decay $\Upsilon(4S) \rightarrow B\bar{B}$ which allows for both flavor ($B^0 \rightarrow \ell^+ X$, $\bar{B}^0 \rightarrow \ell^- X$) and CP ($B_+ \rightarrow J/\psi K_L^0$, $B_- \rightarrow J/\psi K_S^0$) tagging. Comparing the rates of the $\bar{B}^0 \rightarrow B_\pm$ and $B^0 \rightarrow B_\pm$ transitions with their T -reversed $B_\pm \rightarrow \bar{B}^0$ and $B_\pm \rightarrow B^0$ processes, the BABAR experiment has reported the first direct observation of T violation in the B system, with a significance of 14σ .

Among the most powerful tests of P (CP) and T invariance is the search for a permanent electric dipole moment (EDM) of an elementary fermion or non-degenerate quantum system. No positive signal has been detected so far. The most stringent limits have been obtained for the EDMs of the electron, $|d_e| < 1.1 \times 10^{-29}$, mercury atom, $|d_{\text{Hg}}| < 7.4 \times 10^{-30}$ (95% C.L.), and neutron, $|d_n| < 1.8 \times 10^{-26}$.

3 Tests of *CPT*

CPT symmetry implies the equality of the masses and widths of a particle and its antiparticle. The most constraining limits are extracted from the neutral kaons: $2|m_{K^0} - m_{\bar{K}^0}|/(m_{K^0} + m_{\bar{K}^0}) < 6 \times 10^{-19}$ and $2|\Gamma_{K^0} - \Gamma_{\bar{K}^0}|/(\Gamma_{K^0} + \Gamma_{\bar{K}^0}) = (8 \pm 8) \times 10^{-18}$. The measured masses and electric charges of the electron, the proton and their antiparticles provide also strong limits on *CPT* violation: $2|m_{e^+} - m_{e^-}|/(m_{e^+} + m_{e^-}) < 8 \times 10^{-9}$, $|q_{e^+} + q_{e^-}|/e < 4 \times 10^{-8}$ and $|q_{\bar{p}}m_p/(q_p m_{\bar{p}})| - 1 = (0.1 \pm 6.9) \times 10^{-11}$. Worth mentioning are also the tight constraints derived from the lepton and antilepton magnetic moments, $2(g_{e^+} - g_{e^-})(g_{e^+} + g_{e^-}) = (-0.5 \pm 2.1) \times 10^{-12}$ and $2(g_{\mu^+} - g_{\mu^-})(g_{\mu^+} + g_{\mu^-}) = (-0.11 \pm 0.12) \times 10^{-8}$, those of the proton and antiproton, $(\mu_p + \mu_{\bar{p}})/\mu_p = (2 \pm 4) \times 10^{-9}$, and the recent measurement of the 1S-2S atomic transition in antihydrogen which agrees with the corresponding frequency spectral line in hydrogen at a relative precision of 2×10^{-12} .

QUANTUM-NUMBER CONSERVATION LAWS

Conservation laws of several quantum numbers have been empirically established with a high degree of confidence. However, while some of them are deeply rooted in basic principles such as gauge invariance or Lorentz symmetry, others appear to be accidental symmetries of the SM Lagrangian and could be broken by new physics interactions.

4 Electric charge

The conservation of electric charges is associated with the QED gauge symmetry. The most precise tests are the non-observation of the decays $e \rightarrow \nu_e \gamma$ ($\tau > 6.6 \times 10^{28}$ yr) and $n \rightarrow p \nu_e \bar{\nu}_e$ ($\text{Br} < 8 \times 10^{-27}$, 68% C.L.).

5 Lepton family numbers

Neutrino oscillations show that neutrinos have tiny masses and there are sizable mixings among the lepton flavors. Nevertheless, lepton-flavor violation (LFV) in neutrinoless transitions from one charged lepton flavor to another has never been observed. Among the most sensitive probes are searches for the LFV decays of the muon, $\text{Br}(\mu \rightarrow e\gamma) < 4.2 \times 10^{-13}$ and $\text{Br}(\mu \rightarrow 3e) < 1.0 \times 10^{-12}$, as well as the conversion process $\sigma(\mu^- \text{Au} \rightarrow e^- \text{Au})/\sigma(\mu^- \text{Au} \rightarrow \text{all}) < 7 \times 10^{-13}$. Stringent limits have been also set on the LFV decay modes of the τ lepton. The large τ data samples collected at the B factories have made possible to reach a 10^{-8} sensitivity for many of its leptonic ($\tau \rightarrow \ell\gamma$, $\tau \rightarrow \ell'\ell^+\ell^-$) and semileptonic ($\tau \rightarrow \ell P^0$, $\tau \rightarrow \ell V^0$, $\tau \rightarrow \ell P^0 P^0$, $\tau \rightarrow \ell P^+ P^-$) neutrinoless LFV decays. Interesting limits on LFV are also obtained in meson decays. The best bounds come from kaon experiments, e.g., $\text{Br}(K_L^0 \rightarrow e^\pm \mu^\mp) < 4.7 \times 10^{-12}$ and $\text{Br}(K^+ \rightarrow \pi^+ \mu^+ e^-) < 1.3 \times 10^{-11}$.

The LFV decays of the Z boson were probed at LEP at the 10^{-5} to 10^{-6} level. The ATLAS collaboration has recently put the stronger (95% C.L.) bounds $\text{Br}(Z \rightarrow e^\pm \mu^\mp) < 7.5 \times 10^{-7}$, $\text{Br}(Z \rightarrow e^\pm \tau^\mp) < 5.0 \times 10^{-6}$ and $\text{Br}(Z \rightarrow \mu^\pm \tau^\mp) < 6.5 \times 10^{-6}$. LHC is now starting to test LFV in Higgs decays. The current (95% C.L.) experimental upper bounds, $\text{Br}(H^0 \rightarrow e^\pm \mu^\mp) < 6.1 \times 10^{-5}$, $\text{Br}(H^0 \rightarrow e^\pm \tau^\mp) < 0.22\%$ and $\text{Br}(H^0 \rightarrow \mu^\pm \tau^\mp) < 0.15\%$, constrain the LFV Yukawa couplings of the Higgs boson.

6 Baryon and Lepton Number

Many experiments have searched for B - and/or L -violating transitions, but no positive signal has been identified so far. The neutrinoless double- β decay $(Z, A) \rightarrow (Z+2, A) + e^- + e^-$ is a particularly interesting $\Delta L = 2$ process, which could represent a spectacular signal of Majorana neutrinos. The current best limit, $\tau_{1/2} > 1.07 \times 10^{26}$ yr, was obtained by

the KamLAND-Zen experiment with ^{136}Xe . Stringent constraints on violations of L have been also set in $\mu^- \rightarrow e^+$ conversion in muonic atoms, the best limit being $\sigma(\mu^-\text{-Ti} \rightarrow e^+\text{-Ca})/\sigma(\mu^-\text{-Ti} \rightarrow \text{all}) < 3.6 \times 10^{-11}$, and at the flavor factories through L -violating decays of the τ lepton and K , D and B mesons, such as $\text{Br}(\tau^- \rightarrow e^+\pi^-\pi^-) < 2.0 \times 10^{-8}$, $\text{Br}(K^+ \rightarrow \pi^-\mu^+\mu^+) < 4.2 \times 10^{-11}$, $\text{Br}(D^+ \rightarrow \pi^-\mu^+\mu^+) < 1.4 \times 10^{-8}$ and $\text{Br}(B^- \rightarrow \pi^+\mu^-\mu^-) < 4.0 \times 10^{-9}$ (95% CL).

Proton decay would be the most relevant violation of B , as it would imply the instability of matter. The current lower bound on the proton lifetime is 3.6×10^{29} yr. Stronger limits have been set for particular decay modes, such as $\tau(p \rightarrow e^+\pi^0) > 1.6 \times 10^{34}$ yr. Another spectacular signal would be $n-\bar{n}$ oscillations; the lower limit on the lifetime of this $\Delta B = 2$ transition is 8.6×10^7 s (2.7×10^8 s) for free (bound) neutrons.

The search for B -violating decays of short-lived particles such as Z bosons, τ leptons and B mesons provides also relevant constraints. The best limits are $\text{Br}(Z \rightarrow pe, p\mu) < 1.8 \times 10^{-6}$ (95% C.L.), $\text{Br}(\tau^- \rightarrow \bar{p}\mu^-\mu^+) < 1.8 \times 10^{-8}$ and $\text{Br}(B^+ \rightarrow \Lambda e^+) < 3.2 \times 10^{-8}$.

7 Quark flavors

While strong and electromagnetic forces preserve the quark flavor, the charged-current weak interactions generate transitions among the different quark species. Since the SM flavor-changing mechanism is associated with the W^\pm fermionic vertices, the tree-level transitions satisfy a $\Delta F = \Delta Q$ rule where ΔQ denotes the change in charge of the relevant hadrons. The strongest tests on this conservation law have been obtained in kaon decays such as $\text{Br}(K^+ \rightarrow \pi^+\pi^+e^-\bar{\nu}_e) < 1.3 \times 10^{-8}$, and $(\text{Re } x, \text{Im } x) = (-0.002 \pm 0.006, 0.0012 \pm 0.0021)$ where $x \equiv \mathcal{M}(\bar{K}^0 \rightarrow \pi^-\ell^+\nu)/\mathcal{M}(K^0 \rightarrow \pi^-\ell^+\nu)$.

The $\Delta F = \Delta Q$ rule can be violated through quantum loop contributions giving rise to flavor-changing neutral-current transitions (FCNCs). Owing to the GIM mechanism, processes of this type are very suppressed in the SM, which makes them a superb tool in the search for new physics associated with the flavor dynamics. Within the SM, these transitions are also sensitive to the heavy-quark mass scales and have played a crucial role identifying the size of the charm ($K^0-\bar{K}^0$ mixing) and top ($B^0-\bar{B}^0$ mixing) masses before the discovery of those quarks. In addition to the well-established $\Delta F = 2$ mixings in neutral K and B mesons, there is now strong evidence for the mixing of the D^0 meson and its antiparticle.

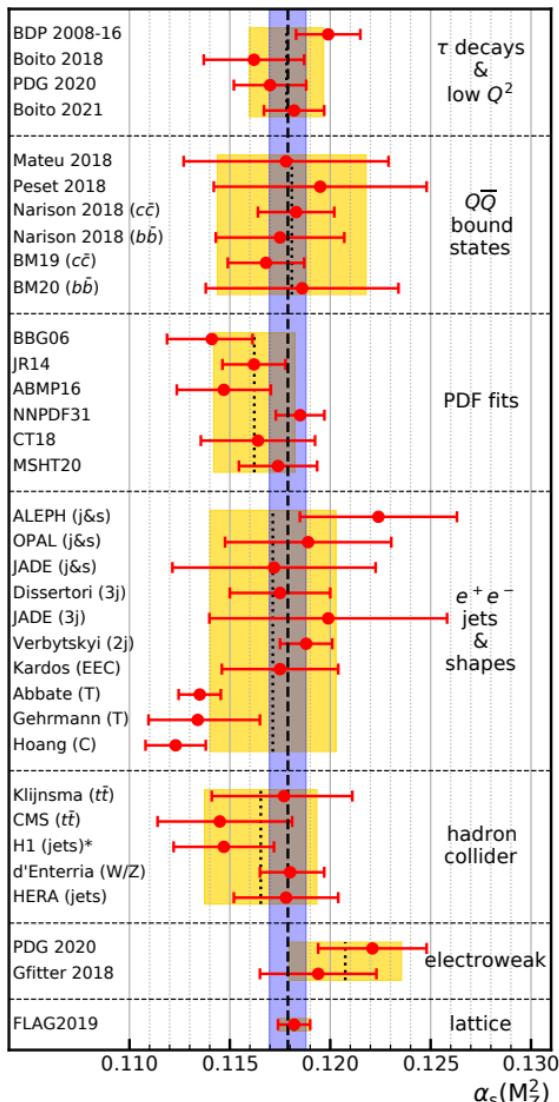

The FCNC kaon decays into lepton-antilepton pairs put stringent constraints on new flavor-changing interactions. The rate $\text{Br}(K_L^0 \rightarrow \mu^+\mu^-) = (6.84 \pm 0.11) \times 10^{-9}$ is completely dominated by the 2γ absorptive contribution, leaving very little room for new-physics. Another very clean test of FCNCs is provided by the decay $K^+ \rightarrow \pi^+\nu\bar{\nu}$. The CERN NA62 experiment has already observed 20 signal candidates, providing the first evidence of this decay. This leads to $\text{Br}(K^+ \rightarrow \pi^+\nu\bar{\nu}) = (1.14_{-0.33}^{+0.40}) \times 10^{-10}$, in agreement with the predicted SM branching fraction of $(7.73 \pm 0.61) \times 10^{-11}$. Even more interesting is the CP -violating neutral mode $K_L^0 \rightarrow \pi^0\nu\bar{\nu}$, but the current upper bound of 3.0×10^{-9} is still far away from the SM prediction.

The LHC experiments have recently measured $\text{Br}(B_s^0 \rightarrow \mu^+\mu^-) = (3.01 \pm 0.35) \times 10^{-9}$, consistent with the SM expectation. At present, there is a lot of interest on the decays $B \rightarrow K^{(*)}\ell^+\ell^-$ where sizable discrepancies between the measured data and the SM predictions have been reported. In particular, the LHCb experiment has found the ratios of produced muons versus electrons to be around 3.1σ (2.4σ) below the SM predictions in $B^+ \rightarrow K^+\ell^+\ell^-$ ($B \rightarrow K^*\ell^+\ell^-$), suggesting a significant violation of lepton universality. The current Belle-II measurements of these ratios are consistent with the SM and the LHCb results.

9. Quantum Chromodynamics

Revised August 2021 by J. Huston (Michigan State U.), K. Rabbertz (KIT) and G. Zanderighi (MPI Munich).

For our world average we combine the determinations from the upper six sub-fields shown in Fig. 9.2 as discussed in the main review. The unweighted average of this combination with the lattice result from FLAG2019 gives our final result of $\alpha_s(M_Z^2) = 0.1179 \pm 0.0009$.

August 2021

Figure 9.2: Summary of determinations of $\alpha_s(M_Z^2)$ from the seven sub-fields discussed in the main review. The yellow (light shaded) bands and dotted lines indicate the pre-average values of each sub-field. The dashed line and blue (dark shaded) band represent the final world average value of $\alpha_s(M_Z^2) = 0.1179 \pm 0.0009$.

10. Electroweak Model and Constraints on New Physics

Revised April 2022 by J. Erler (KPH, JGU Mainz) and A. Freitas (Pittsburgh U.).

The standard model of the electroweak interactions (SM) [1–4] is based on the gauge group $SU(2) \times U(1)$, with gauge bosons W_μ^i , $i = 1, 2, 3$, and B_μ for the $SU(2)$ and $U(1)$ factors, respectively, and the corresponding gauge coupling constants g and g' .

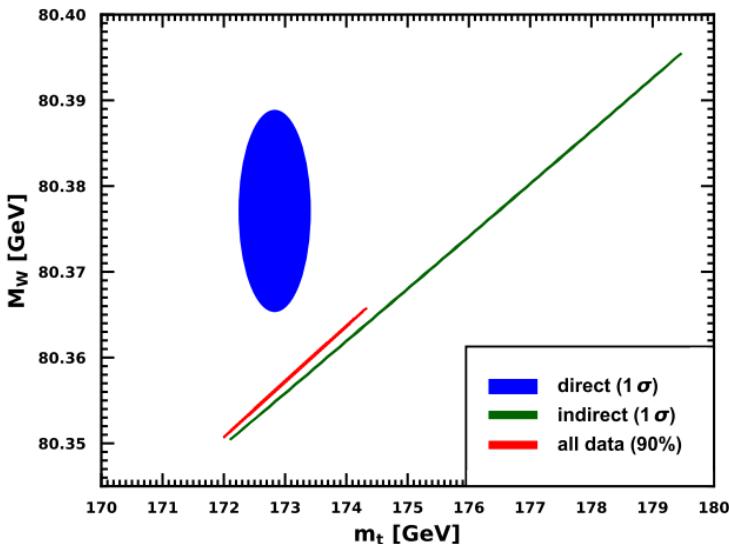

Figure 10.5: One-standard-deviation (39.35%) regions in M_W as a function of m_t for the direct and indirect data, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data.

Table 10.5: A selection of Z pole observables and their SM predictions. The first \bar{s}_ℓ^2 is the combined value from the Tevatron [279], and the second is from the LHC [280–283]. The values of A_e is from A_{LR} for hadronic final states [284]. Note that the SM errors in Γ_Z , the R_ℓ , and σ_{had} are largely dominated by the uncertainty in α_s .

Quantity	Value	Standard Model	Pull
M_Z [GeV]	91.1876 ± 0.0021	91.1882 ± 0.00020	-0.3
Γ_Z [GeV]	2.4955 ± 0.0023	2.4941 ± 0.0009	0.6
σ_{had} [nb]	41.481 ± 0.033	41.482 ± 0.008	0.0

LHC	0.23116(10)	0.22340(12)	0.1187(16)	172.6 ± 0.6	125
Tevatron + M_Z	0.23103(14)	0.22294(30)	0.1160(45)	174.3 ± 0.8	99^{+31}_{-27}
LEP 1 + LEP 2	0.23137(18)	0.22352(46)	0.1234(29)	178 ± 11	195^{+267}_{-109}
LEP 1 + SLD	0.23116(17)	0.22345(58)	0.1221(27)	169 ± 10	79^{+100}_{-38}
SLD + $M_Z + \Gamma_Z + m_t$	0.23064(28)	0.22226(54)	0.1191(48)	172.8 ± 0.6	36^{+29}_{-21}
$A_{FB}^{(b,c)} + M_Z + \Gamma_Z + m_t$	0.23176(27)	0.22465(66)	0.1267(45)	172.8 ± 0.6	273^{+140}_{-98}
$M_{W,Z} + \Gamma_{W,Z} + m_t$	0.23106(12)	0.22306(25)	0.1201(42)	172.8 ± 0.6	86^{+23}_{-20}
low energy + $M_{H,Z}$	0.23174(94)	0.2253(35)	0.1172 (18)	157 ± 29	125

The masses and decay properties of the electroweak bosons and low energy data can be used to search for and set limits on deviations from the SM.

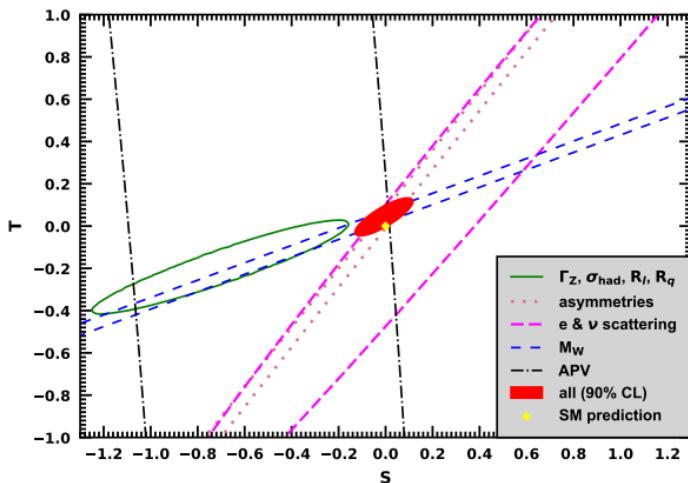

Figure 10.6: 1σ constraints (39.35% for the closed contours and 68% for the others) on S and T (for $U = 0$) from various inputs combined with M_Z . S and T represent the contributions of new physics only. Data sets not involving M_W or Γ_W are insensitive to U . With the exception of the fit to all data, we fix $\alpha_s = 0.1185$. The black dot indicates the Standard Model values $S = T = 0$.

11. Status of Higgs Boson Physics

Revised November 2021 by M. Carena (FNAL; Chicago U.; Chicago U., Kavli Inst.), C. Grojean (DESY, Hamburg; Physik, Humboldt U.), M. Kado (Rome U. Sapienza; INFN, Rome; U. Paris-Saclay, IJCLab) and V. Sharma (UC San Diego).

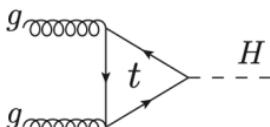

The discovery of the Higgs boson in 2012 confirmed our understanding of the fundamental interactions based on local symmetries spontaneously broken by a non-trivial vacuum structure. It also offered an explanation of the generation of mass in a chiral theory. However, new conundrums about what lies beyond the Standard Model (SM) have come fore.

Since 2012, substantial progress has been made, yielding an increasingly precise profile of the properties of the Higgs boson. New landmark results have been achieved in the direct observation of the couplings of the Higgs boson to the third generation fermions (the τ^\pm and the b and top quarks) and sensitivity to the couplings to the second generation is being reached.

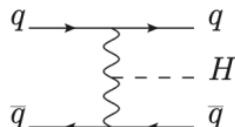

Within the SM, all the production and decay rates of the Higgs boson can be predicted to high accuracy in terms of its mass and of other parameters already known with great accuracy, so the measurements in the Higgs sector appraise the robustness of the SM.

Total SM production cross-section at LHC operating at 13 TeV

$$\sigma_{\text{tot}}^{13 \text{ TeV}}(H) = 55.1 \pm 3.3 \text{ pb}$$

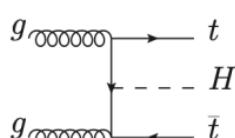

$$\sigma(ggH) = 48.6 \pm 2.8 \text{ pb}$$

$$\sigma(\text{VBF}) = 3.78 \pm 0.08 \text{ pb}$$

$$\sigma(WH, ZH) = 1.37 \pm 0.03, 0.88 \pm 0.03 \text{ pb}$$

$$\sigma(t\bar{t}H) = 0.50 \pm 0.04 \text{ pb}$$

Total SM Higgs boson width

$$\Gamma_H = (4.07 \pm 4.0\%) \text{ MeV}$$

Main SM branching ratios and their relative uncertainty

$$\begin{aligned} \text{Br}(H \rightarrow b\bar{b}) &= (5.82 \pm 1.2\%) \times 10^{-1} & \text{Br}(H \rightarrow WW) &= (2.14 \pm 1.5\%) \times 10^{-1} \\ \text{Br}(H \rightarrow \tau\bar{\tau}) &= (6.27 \pm 1.6\%) \times 10^{-2} & \text{Br}(H \rightarrow ZZ) &= (2.62 \pm 1.5\%) \times 10^{-2} \\ \text{Br}(H \rightarrow \gamma\gamma) &= (2.27 \pm 2.1\%) \times 10^{-3} & \text{Br}(H \rightarrow Z\gamma) &= (1.53 \pm 5.8\%) \times 10^{-3} \\ \text{Br}(H \rightarrow c\bar{c}) &= (2.89 \pm 3.75\%) \times 10^{-2} & \text{Br}(H \rightarrow \mu\bar{\mu}) &= (2.18 \pm 1.7\%) \times 10^{-4} \end{aligned}$$

Figure: Main leading order Feynman diagrams contributing to the Higgs production at the LHC. The SM predictions for the production cross sections at a centre-of-mass energy of 13 TeV and the branching fractions for the dominant decay modes are indicated assuming a Higgs boson mass of 125 GeV.

The ATLAS and CMS experiments have measured the mass of the Higgs boson in the diphoton and the four-lepton channels at per mille precision, $m_H = 125.25 \pm 0.17$ GeV. The quantum numbers of the Higgs boson have been probed in greater detail and show an excellent consistency with the $J^{PC} = 0^{++}$ hypothesis.

The coupling structure of the Higgs boson has been studied in a large number of channels, in the main production mechanisms at the LHC which are illustrated in the Figure. The Table summarises the ATLAS and CMS measurements and limits on the cross sections times branching ratios, normalised to their SM expectations in the main Higgs analysis channels. Further information on the couplings of the Higgs boson are also obtained from differential cross sections and searches for rare and exotic production and decay modes, including invisible decays.

All measurements are consistent with the SM predictions and provide stringent constraints on a large number of scenarios of new physics.

The review discusses in detail the latest developments in theories extending the SM to solve the fundamental questions raised by the existence of the Higgs boson.

Table: Summary of the ATLAS (A) and CMS (C) measurements of the signal strengths in the various channels (the products of the production rates times the branching ratios normalised to their SM values). Results for the rare modes are reported in the column corresponding to the primary production mode, while the secondary production modes used in the analyses are indicated as “Incl.”. Limits on the invisible (“Inv.”) are set at 95% confidence level, and the expected sensitivities are given in parentheses.

12. CKM Quark-Mixing Matrix

Revised March 2022 by A. Ceccucci (CERN), Z. Ligeti (LBNL) and Y. Sakai (KEK).

Highlights from full review.

The Cabibbo-Kobayashi-Maskawa (CKM) matrix [1, 2] is a 3×3 unitary matrix. It can be parameterized [3] by three mixing angles and the CP -violating KM phase [2],

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{pmatrix} \begin{pmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13} \end{pmatrix} \begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (12.3)$$

Here $s_{ij} = \sin \theta_{ij}$, $c_{ij} = \cos \theta_{ij}$, and δ is the phase responsible for all CP -violating phenomena in flavor-changing processes in the SM. The angles θ_{ij} can be chosen to lie in the first quadrant, so $s_{ij}, c_{ij} \geq 0$.

Motivated by the Wolfenstein parameterization to exhibit the hierarchical structure of the CKM matrix, we define [4–6]

$$\begin{aligned} s_{12} = \lambda &= \frac{|V_{us}|}{\sqrt{|V_{ud}|^2 + |V_{us}|^2}}, & s_{23} = A\lambda^2 &= \lambda \left| \frac{V_{cb}}{V_{us}} \right|, \\ s_{13}e^{i\delta} = V_{ub}^* &= A\lambda^3(\rho + i\eta) = \frac{A\lambda^3(\bar{\rho} + i\bar{\eta})\sqrt{1 - A^2\lambda^4}}{\sqrt{1 - \lambda^2}[1 - A^2\lambda^4(\bar{\rho} + i\bar{\eta})]}. \end{aligned} \quad (12.4)$$

These ensure that $\bar{\rho} + i\bar{\eta} = -(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)$ is phase convention independent, and the CKM matrix written in terms of λ , A , $\bar{\rho}$, and $\bar{\eta}$ is unitary to all orders in λ . To $\mathcal{O}(\lambda^4)$ one can write V_{CKM} as

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (12.5)$$

The unitarity implies $\sum_i V_{ik}V_{ik}^* = \delta_{jk}$ and $\sum_j V_{ij}V_{kj}^* = \delta_{ik}$. The six vanishing combinations can be represented as triangles in a complex plane. The areas of all triangles are the same and are half of the Jarlskog invariant, J [7], which is a phase-convention-independent measure of CP violation, defined by $\text{Im}[V_{ij}V_{kl}V_{il}^*V_{kj}^*] = J \sum_{m,n} \varepsilon_{ikm}\varepsilon_{jln}$. The most commonly used unitarity triangle arises from

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0, \quad (12.6)$$

by dividing each side by the best-known one, $V_{cd}V_{cb}^*$ (see Fig. 12.1).

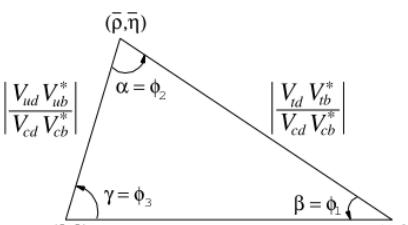

Figure 12.1: Sketch of the unitarity triangle.

The magnitudes of the independently measured CKM elements are

$$|V_{CKM}| = \begin{pmatrix} 0.97373 \pm 0.00031 & 0.2243 \pm 0.0008 & 0.00382 \pm 0.00020 \\ 0.221 \pm 0.004 & 0.975 \pm 0.006 & 0.0408 \pm 0.0014 \\ 0.0086 \pm 0.0002 & 0.0415 \pm 0.0009 & 1.014 \pm 0.029 \end{pmatrix},$$

and the angles of the unitarity triangle are

$$\sin(2\beta) = 0.699 \pm 0.017, \quad \alpha = (85.2^{+4.8}_{-4.3})^\circ, \quad \gamma = (65.9^{+3.3}_{-3.5})^\circ.$$

Using those values, one can check the unitarity of the CKM matrix: $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9985 \pm 0.0007$ (1st row), $|V_{cd}|^2 + |V_{cs}|^2 + |V_{cb}|^2 = 1.001 \pm 0.012$ (2nd row), $|V_{ud}|^2 + |V_{cd}|^2 + |V_{td}|^2 = 0.9972 \pm 0.0020$ (1st column), and $|V_{us}|^2 + |V_{cs}|^2 + |V_{ts}|^2 = 1.004 \pm 0.012$ (2nd column).

12.4 Global fit in the Standard Model

A global fit with three generation unitarity imposed gives

$$\begin{aligned} \lambda &= 0.22500 \pm 0.00067, & A &= 0.826^{+0.018}_{-0.015}, \\ \bar{\rho} &= 0.159 \pm 0.010, & \bar{\eta} &= 0.348 \pm 0.010. \end{aligned} \quad (12.26)$$

$$|V_{CKM}| = \begin{pmatrix} 0.97435 \pm 0.00016 & 0.22500 \pm 0.00067 & 0.00369 \pm 0.00011 \\ 0.22486 \pm 0.00067 & 0.97349 \pm 0.00016 & 0.04182^{+0.00085}_{-0.00074} \\ 0.00857^{+0.00020}_{-0.00018} & 0.04110^{+0.00083}_{-0.00072} & 0.999118^{+0.000031}_{-0.000036} \end{pmatrix}, \quad (12.27)$$

and the Jarlskog invariant, $J = (3.08^{+0.15}_{-0.13}) \times 10^{-5}$. The parameters in Eq. (12.3) are

$$\begin{aligned} \sin \theta_{12} &= 0.22500 \pm 0.00067, & \sin \theta_{13} &= 0.00369 \pm 0.00011, \\ \sin \theta_{23} &= 0.04182^{+0.00085}_{-0.00074}, & \delta &= 1.144 \pm 0.027. \end{aligned} \quad (12.28)$$

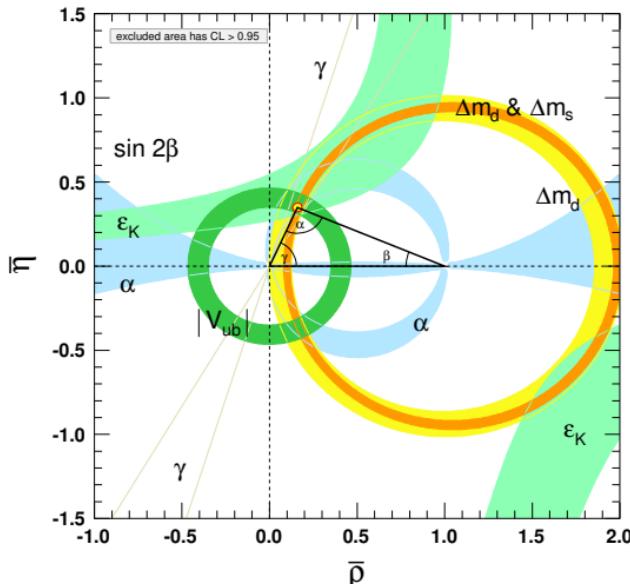

Figure 12.2: Constraints on $\bar{\rho}$ and $\bar{\eta}$. The shaded areas have 95% CL.

13. CP Violation in the Quark Sector

Revised August 2021 by T. Gershon (Warwick U.) and Y. Nir (Weizmann Inst.).

Within the Standard Model, CP symmetry is broken by complex phases in the Yukawa couplings (that is, the couplings of the Higgs scalar to quarks). When all transformations to remove unphysical phases in this model are exhausted, a single CP -violating parameter remains [19]. In the basis of mass eigenstates, this single phase appears in the 3×3 unitary matrix that gives the W -boson couplings to an up-type anti-quark and a down-type quark. The beautifully consistent and economical Standard-Model description of CP violation in terms of Yukawa couplings, known as the Kobayashi-Maskawa (KM) mechanism [19], agrees with all measurements to date. Furthermore, one can fit the data allowing new physics contributions to loop processes to compete with, or even dominate over, the Standard Model amplitudes [20] [21]. Such analyses provide model-independent proof that the KM phase is different from zero, and that the matrix of three-generation quark mixing is the dominant source of CP violation in meson decays.

The current level of experimental accuracy and the theoretical uncertainties involved in the interpretation of the various observations leave room, however, for additional subdominant sources of CP violation from new physics. Indeed, almost all extensions of the Standard Model imply that there are such additional sources. Moreover, CP violation is a necessary condition for baryogenesis, the process of dynamically generating the matter-antimatter asymmetry of the Universe [22]. Despite the phenomenological success of the KM mechanism, it fails (by several orders of magnitude) to accommodate the observed asymmetry [23]. This discrepancy strongly suggests that Nature provides additional sources of CP violation beyond the KM mechanism. The expectation of new sources motivates the large ongoing experimental effort to find deviations from the predictions of the KM mechanism.

Using the notation M^0 to represent generically one of the K^0 , D^0 , B^0 or B_s^0 particles, we denote the state of an initially pure $|M^0\rangle$ or $|\bar{M}^0\rangle$ after an elapsed proper time t as $|M_{\text{phys}}^0(t)\rangle$ or $|\bar{M}_{\text{phys}}^0(t)\rangle$, respectively. Defining $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta\Gamma/(2\Gamma)$, where Δm and $\Delta\Gamma$ are the mass and width differences between the two eigenstates of the effective Hamiltonian, $|M_L\rangle \propto p|M^0\rangle + q|\bar{M}^0\rangle$ and $|M_H\rangle \propto p|M^0\rangle - q|\bar{M}^0\rangle$, and Γ is their average width, one obtains the following time-dependent rates for decay to a final state f :

$$\begin{aligned} & \frac{1}{e^{-\Gamma t} \mathcal{N}_f} d\Gamma \left[M_{\text{phys}}^0(t) \rightarrow f \right] / dt = \\ & |A_f|^2 \left\{ (1 + |\lambda_f|^2) \cosh(y\Gamma t) + (1 - |\lambda_f|^2) \cos(x\Gamma t) \right. \\ & \quad \left. + 2\mathcal{R}e(\lambda_f) \sinh(y\Gamma t) - 2\mathcal{I}m(\lambda_f) \sin(x\Gamma t) \right\}, \\ & \frac{1}{e^{-\Gamma t} \mathcal{N}_f} d\Gamma \left[\bar{M}_{\text{phys}}^0(t) \rightarrow f \right] / dt = \\ & |(p/q)A_f|^2 \left\{ (1 + |\lambda_f|^2) \cosh(y\Gamma t) - (1 - |\lambda_f|^2) \cos(x\Gamma t) \right. \\ & \quad \left. + 2\mathcal{R}e(\lambda_f) \sinh(y\Gamma t) + 2\mathcal{I}m(\lambda_f) \sin(x\Gamma t) \right\}, \end{aligned}$$

where \mathcal{N}_f is a normalization factor and $\lambda_f = (q/p)(\bar{A}_f/A_f)$ with A_f (\bar{A}_f) the amplitude for the M^0 (\bar{M}^0) $\rightarrow f$ decay. Considering the case that f is a CP eigenstate, we distinguish three types of CP -violating effects that can occur in the quark sector:

I. CP violation in decay, defined by $|\bar{A}_f/A_f| \neq 1$.

II. CP violation in mixing, defined by $|q/p| \neq 1$.

III. CP violation in interference between decays with and without mixing, defined by $\arg(\lambda_f) \neq 0$.

It is also common to refer to *indirect CP violation* effects, which are consistent with originating from a single CP violating phase in neutral meson mixing, and *direct CP violation* effects, which cannot be explained in this way. CP violation in mixing (type II) is indirect; CP violation in decay (type I) is direct.

Many CP violating observables have been studied by experiments. Here we summarise only a sample of the most important measurements, including some parameters defined using common notation for the asymmetry between $\bar{B}_{\text{phys}}^0(t)$ and $B_{\text{phys}}^0(t)$ time-dependent decay rates

$$\mathcal{A}_f(t) = S_f \sin(\Delta mt) - C_f \cos(\Delta mt),$$

$$\text{where } S_f \equiv 2 \mathcal{I}m(\lambda_f) / \left(1 + |\lambda_f|^2\right), C_f \equiv \left(1 - |\lambda_f|^2\right) / \left(1 + |\lambda_f|^2\right).$$

- Indirect CP violation in $K \rightarrow \pi\pi$ and $K \rightarrow \pi\ell\nu$ decays, given by

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}.$$

- Direct CP violation in $K \rightarrow \pi\pi$ decays, given by

$$\mathcal{R}e(\epsilon'/\epsilon) = (1.65 \pm 0.26) \times 10^{-3}.$$

- Direct CP violation has been established in the difference of asymmetries for $D^0 \rightarrow K^+K^-$ and $D^0 \rightarrow \pi^+\pi^-$ decays

$$\Delta a_{CP} = (-0.164 \pm 0.028) \times 10^{-2}.$$

- CP violation in the interference of mixing and decay in the tree-dominated $b \rightarrow c\bar{s}$ transitions, such as $B^0 \rightarrow \psi K_S$, given by

$$S_{\psi K^0} = +0.699 \pm 0.017.$$

Within the Standard Model, this result can be interpreted with low theoretical uncertainty as measurement of $\sin(2\beta)$, where β is an angle of the unitarity triangle.

- Direct CP violation in $B^0 \rightarrow K^+\pi^-$ and $B_s^0 \rightarrow K^-\pi^+$ decays is given by

$$\mathcal{A}_{B^0 \rightarrow K^+\pi^-} = -0.082 \pm 0.006, \quad \mathcal{A}_{B_s^0 \rightarrow K^-\pi^+} = +0.225 \pm 0.012.$$

- The CP violation parameters in the $B^0 \rightarrow \pi^+\pi^-$ mode,

$$S_{\pi^+\pi^-} = -0.67 \pm 0.03, \quad C_{\pi^+\pi^-} = -0.31 \pm 0.03.$$

Together with measurements of other $B \rightarrow \pi\pi$ and similar decays, these results can be used to obtain constraints on the angle α of the unitarity triangle.

- Direct CP violation in $B^+ \rightarrow DK^+$ decays, where D_+ and $D_{K^-\pi^+}$ represent that the D meson is reconstructed in a CP -even and the suppressed $K^-\pi^+$ final state respectively,

$$\mathcal{A}_{B^+ \rightarrow D_+ K^+} = +0.139 \pm 0.009, \quad \mathcal{A}_{B^+ \rightarrow D_{K^-\pi^+} K^+} = -0.453 \pm 0.026.$$

Together with measurements of other $B \rightarrow DK$ and similar decays, these results can be used to obtain constraints on the angle γ of the unitarity triangle.

14. Neutrino Masses, Mixing, and Oscillations

Revised October 2021 by M.C. Gonzalez-Garcia (YITP, Stony Brook; ICREA, Barcelona; ICC, U. of Barcelona) and M. Yokoyama (UTokyo; Kavli IPMU (WPI), UTokyo).

The weak neutrino eigenstates $|\nu_\alpha\rangle$, i. e. the states produced in the weak CC interaction by the charged leptons ℓ_α ($\alpha = 1, 2, 3$), are linear combination of the mass eigenstates $|\nu_i\rangle$ ($i = 1, 2, 3$) (eigenvalues m_i)

$$|\nu_\alpha\rangle = \sum_{i=1}^n U_{\alpha i}^* |\nu_i\rangle, \quad (14.35)$$

where U is the mixing matrix. U , assumed to be unitary, can be expressed in terms of three mixing angles, taken by convention $0 \leq \theta_{ij} \leq \pi/2$, and phases $\in (0, 2\pi)$. Experimentally, two masses are close to one another, while the third is more separated. The former ones are defined as ν_1 and ν_2 , with the lighter being ν_1 . The sign of the larger mass difference defines two possible mass orderings, either “normal” (NO) $m_3 > m_2 > m_1$, or “inverted” (IO) $m_2 > m_1 > m_3$. Experiments show that $|U_{e1}| \geq |U_{e2}| \geq |U_{e3}|$. The mixing matrix is given by

$$U =$$

$$\begin{pmatrix} c_{12} c_{13} & s_{12} c_{13} & s_{13} e^{-i\delta} \\ -s_{12} c_{23} - c_{12} s_{13} s_{23} e^{i\delta} & c_{12} c_{23} - s_{12} s_{13} s_{23} e^{i\delta} & c_{13} s_{23} \\ s_{12} s_{23} - c_{12} s_{13} c_{23} e^{i\delta} & -c_{12} s_{23} - s_{12} s_{13} c_{23} e^{i\delta} & c_{13} c_{23} \end{pmatrix} \times \text{diag}(e^{i\eta_1}, e^{i\eta_2}, 1) \quad (14.33)$$

where $c_{ij} = \cos \theta_{ij}$, $s_{ij} = \sin \theta_{ij}$, $\delta = \delta_{\text{CP}}$. The phases η_1 and η_2 are physical if neutrinos are Majorana particles (but irrelevant for oscillations and matter effects), while can be absorbed in the wave functions in the Dirac case. For propagation in vacuum, assuming the state $|\nu_\alpha(t)\rangle$ to be a plane monoenergetic ultra-relativistic wave (namely $p \sim E$), the oscillation probability between two flavours α and β is

$$P_{\alpha\beta} = \delta_{\alpha\beta} - 4 \sum_{i < j}^n \Re[U_{\alpha i} U_{\beta i}^* U_{\alpha j}^* U_{\beta j}] \sin^2 X_{ij} + 2 \sum_{i < j}^n \Im[U_{\alpha i} U_{\beta i}^* U_{\alpha j}^* U_{\beta j}] \sin 2X_{ij}, \quad (14.39)$$

where

$$X_{ij} = \frac{(m_i^2 - m_j^2)L}{4E} = 1.267 \frac{\Delta m_{ij}^2}{\text{eV}^2} \frac{L/E}{\text{m/MeV}}. \quad (14.40)$$

When neutrinos propagate in a dense medium, while absorption is negligible, the effect of coherent interaction with matter, being proportional to G_F , rather than to G_F^2 , is not; it affects neutrino phase velocity. In a neutral medium containing nuclei and electrons, the effective potential at point x , with electron density $n_e(x)$, is

$$V = \text{diag}(\pm \sqrt{2}G_F n_e(x), 0, 0) \quad (14.58)$$

Where the sign + is for neutrinos, – for antineutrinos. In the relevant case of solar neutrinos, ν_e are produced in the core. The propagating system is effectively a two-state one, $\nu_e - \nu_X$ (X is a superposition of ν_μ and ν_τ , which is arbitrary because ν_μ and ν_τ have only NC that are equal). If θ is the mixing angle (in vacuum) and Δm^2 the square mass difference, the instantaneous mixing angle in matter $\theta_m(x)$ is given by

$$\tan 2\theta_m(x) = \frac{\Delta m^2 \sin 2\theta}{\Delta m^2 \cos 2\theta - 2EG_F n_e(x)}. \quad (14.61)$$

Depending on neutrino energy and mixing angle in vacuum, the denominator can cross zero at a certain x . This “resonance” condition may result in an adiabatic flavour conversion in matter (Mikheev-Smirnov-Wolfenstein Effect). The mixing parameters are obtained from global fits to the neutrino data, relative to both phenomena. Fits are performed by three different groups (NUFIT, BARI and VALENCIA), separately for NO and IO. The following is a summary of Table 14.7 of the main review (NUFIT without the SuperKamiokande analysis of matter effects in atmospheric neutrinos)

Table 14.7: Global fit results

Parameter	NUFIT w/o SK-at	BARI	VALENCIA
NO			
$\sin^2 \theta_{12}/10^{-1}$	$3.10^{+0.13}_{-0.12}$	$3.04^{+0.14}_{-0.13}$	$3.20^{+0.20}_{-0.16}$
$\sin^2 \theta_{23}/10^{-1}$	$5.58^{+0.20}_{-0.33}$	$5.51^{+0.19}_{-0.80}$	$5.47^{+0.20}_{-0.30}$
$\sin^2 \theta_{13}/10^{-2}$	$2.241^{+0.066}_{-0.065}$	$2.14^{+0.09}_{-0.07}$	$2.160^{+0.063}_{-0.066}$

$\Delta m_{32}^2/\text{meV}^2$	-2509^{+32}_{-32}	-2478^{+35}_{-33}	-2500^{+40}_{-30}

Fig. 14.9 shows the allowed regions of the NUFIT analysis in terms, as an example, of one of the six leptonic unitary triangles (taking U as unitary by definition)

Information on the absolute scale of neutrino masses comes from three different sources.

- 1 Cosmology provides indirect limits on the sum of neutrino masses
$$\sum_{i=1}^3 m_i$$
 (see Sec. 25. Neutrinos in cosmology).

- 2 Measurements, with sub-eV energy resolution, of the end-point of the electron energy spectrum in the decay ${}^3\text{H} \rightarrow {}^3\text{He} + e^- + \bar{\nu}_e$ gives direct information on $(m_{\nu_e}^{\text{eff}})^2 = \sum_{i=1}^3 m_i^2 |U_{ei}|^2$. First result released by the KATRIN experiment provide $m_{\nu_e}^{\text{eff}} < 1.1 \text{ eV}$ at 90% CL.

3 Neutrino-less double beta decay $(A, Z) \rightarrow (A, Z + 2) + 2e^-$ is forbidden in the SM as it violates lepton number conservation (by 2 units). However, if neutrino is a Majorana particle measurements of the half-lives $T_{1/2}^{0\nu}$ of different isotopes give information

on $m_{ee} = \left| \sum_{i=1}^3 m_i U_{ei}^2 \right|$. The sensitivity reached by experiments on ^{136}Xe and ^{76}Ge , $T_{1/2}^{0\nu} > 1.07 \times 10^{26}$ yr, and $T_{1/2}^{0\nu} > 1.8 \times 10^{26}$ yr, give bounds of $m_{ee} < 61 - 165$ meV and $m_{ee} < 79 - 180$ meV respectively.

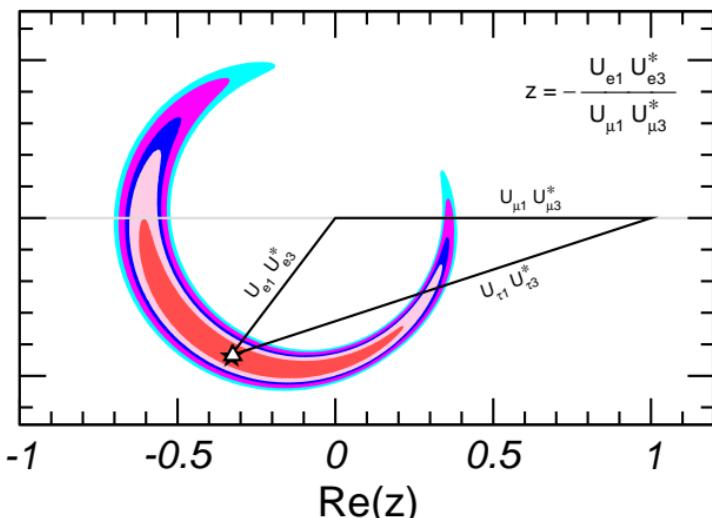

Figure 14.9: Leptonic unitarity triangle for the first and third columns of the mixing matrix. After scaling and rotating the triangle so that two of its vertices always coincide with $(0, 0)$ and $(1, 0)$ the figure shows the 1σ , 90%, 2σ , 99%, 3σ CL (2 dof) allowed regions of the third vertex for the NO from the analysis in Ref. [184, 185].

15. Quark Model

Revised August 2021 by C. Amsler (Stefan Meyer Inst.), T. DeGrand (Colorado U., Boulder) and B. Krusche (Basel U.).

Quarks (q) are strongly interacting fermions with spin $\frac{1}{2}$ and, by convention, positive parity. Antiquarks (\bar{q}) have negative parity. Quarks have the additive baryon number $B = \frac{1}{3}$, while antiquarks have $B = -\frac{1}{3}$. Table 15.1 gives the other additive quantum numbers for the three generations of quarks. They are related to the charge Q (in units of the elementary charge e) through the generalized Gell-Mann-Nishijima formula

$$Q = I_z + \frac{B + S + C + B + T}{2}. \quad (15.1)$$

By convention the quark *flavor* (I_z , S , C , B , or T) has the same sign as its *charge* Q .

Table 15.1: Quark quantum numbers.

	d	u	s	c	b	t
Q – electric charge	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$
I – isospin	$\frac{1}{2}$	$\frac{1}{2}$	0	0	0	0
I_z – isospin z -component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	-1	0	0	0
C – charm	0	0	0	+1	0	0
B – bottomness	0	0	0	0	-1	0
T – topness	0	0	0	0	0	+1

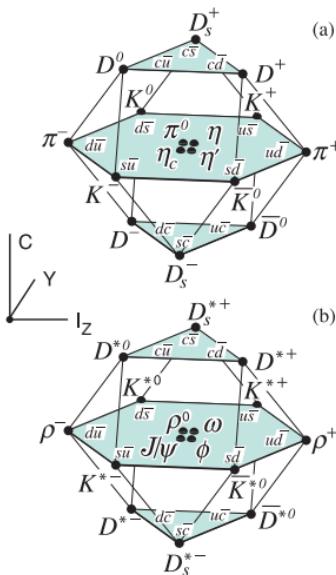

Figure 15.1: $SU(4)_f$ weight diagram showing the 16-plets for the pseudoscalar (a) and vector mesons (b) made of the u , d , s , and c quarks as a function of isospin I_z , charm C , and hypercharge $Y = B + S - \frac{C}{3}$. The nonets of light mesons occupy the central planes to which the $c\bar{c}$ states have been added.

The mesons, which are pairs of quarks and antiquarks, have $B = 0$ and can be characterized by their intrinsic spin s , orbital angular momentum ℓ , and total spin J , lying between $|\ell - s|$ and $\ell + s$. The

charge conjugation, or C , of meson is $(-1)^{\ell+s}$ while its parity is $(-1)^{\ell+1}$. Mesons made of a quark and its antiquark are G -parity eigenstates with $G = (-1)^{I+\ell+s}$.

Following flavor $SU(3)_f$, the nine possible $q\bar{q}'$ combinations containing the light u , d , and s quarks are grouped into an octet and a singlet of light quark mesons:

$$\mathbf{3} \otimes \overline{\mathbf{3}} = \mathbf{8} \oplus \mathbf{1}. \quad (15.2)$$

A fourth quark such as charm c can be included by extending $SU(3)_f$ to $SU(4)_f$. However, $SU(4)_f$ is badly broken owing to the much heavier c quark. Nevertheless, in an $SU(4)_f$ classification, the sixteen mesons are grouped into a 15-plet and a singlet:

$$\mathbf{4} \otimes \overline{\mathbf{4}} = \mathbf{15} \oplus \mathbf{1}. \quad (15.3)$$

The *weight diagrams* for the ground state ($\ell = 0$) pseudoscalar ($J^{PC} = 0^{-+}$) and vector (1^{--}) mesons are depicted in Fig. 15.1.

Baryons are made of three quarks. The $SU(3)_f$ content of baryons made of u , d , and s is governed by

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1}. \quad (15.31)$$

The intrinsic spin of the three quarks yields either $s = \frac{1}{2}$ or $s = \frac{3}{2}$. The proton and neutron are members of a combination of the two octets, while the spin- $\frac{3}{2}$ Δ^{++} is a member of a decuplet. The singlet is not realized for the ground state mesons.

The strong interactions are described by the *color* $SU(3)$ gauge theory, with each quark coming in three ‘colors’. The quarks interact through a color octet of gluons, gauge vector bosons which are responsible for the formation of the bound states, mesons and baryons.

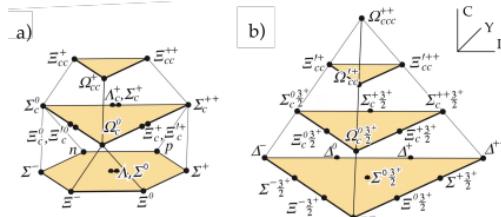

Figure 15.5: $SU(4)_f$ multiplets of ground state baryons made of u , d , s , and c quarks. (a) The spin $\frac{1}{2}$ 20-plet extends the charmless $SU(3)_f$ octet to $C = 1, 2$; (b) the spin $\frac{3}{2}$ 20-plet extends the $SU(3)_f$ decuplet to $C = 1, 2, 3$.

The existence of baryons with t quarks is very unlikely due to the short lifetime of the t quark. Meson candidates which cannot be (or are hard to be) described as $q\bar{q}'$ pairs have been reported (*e.g.* with the non- $q\bar{q}$ quantum number $J^{PC} = 1^{-+}$). Given the successes of the quark model, these are classified as ‘tetraquarks’ ($qq\bar{q}\bar{q}$), hybrids ($q\bar{q}$ pairs with an additional gluon) or ‘glueballs’ (bound states of the gluons). Candidate baryons for ‘pentaquarks’ ($qqqq\bar{q}$) have also been reported.

22. Big-Bang Cosmology

Revised August 2021 by K.A. Olive (Minnesota U.) and J.A. Peacock (Edinburgh U.).

22.1.1 The Robertson-Walker Universe

The observed homogeneity and isotropy enable us to write the most general expression for a space-time metric which has a (3D) maximally symmetric subspace of a 4D space-time, known as the Robertson-Walker metric:

$$ds^2 = dt^2 - R^2(t) \left[\frac{dr^2}{1 - kr^2} + r^2 (d\theta^2 + \sin^2 \theta d\phi^2) \right]. \quad (22.1)$$

Note that we adopt $c = 1$ throughout. By rescaling the radial coordinate, we can choose the curvature constant k to take only the discrete values $+1, -1$, or 0 corresponding to closed, open, or spatially flat geometries.

22.1.3 The Friedmann equations of motion

The cosmological equations of motion are derived from Einstein's equations

$$\mathcal{R}_{\mu\nu} - \frac{1}{2}g_{\mu\nu}\mathcal{R} = 8\pi G_N T_{\mu\nu} + \Lambda g_{\mu\nu} \quad (22.6)$$

It is common to assume that the matter content of the Universe is a perfect fluid, for which

$$T_{\mu\nu} = -pg_{\mu\nu} + (p + \rho)u_\mu u_\nu, \quad (22.7)$$

where $g_{\mu\nu}$ is the space-time metric described by Eq. (22.1), p is the isotropic pressure, ρ is the energy density and $u = (1, 0, 0, 0)$ is the velocity vector for the isotropic fluid in co-moving coordinates. With the perfect fluid source, Einstein's equations lead to the Friedmann equations

$$H^2 \equiv \left(\frac{\dot{R}}{R} \right)^2 = \frac{8\pi G_N \rho}{3} - \frac{k}{R^2} + \frac{\Lambda}{3}, \quad (22.8)$$

and

$$\frac{\ddot{R}}{R} = \frac{\Lambda}{3} - \frac{4\pi G_N}{3} (\rho + 3p), \quad (22.9)$$

where $H(t)$ is the Hubble parameter and Λ is the cosmological constant. The first of these is sometimes called the Friedmann equation. Energy conservation via $T_{;\mu}^{\mu\nu} = 0$, leads to a third useful equation

$$\dot{\rho} = -3H(\rho + p). \quad (22.10)$$

Eq. (22.10) can also be simply derived as a consequence of the first law of thermodynamics.

22.1.5 Standard Model solutions

22.1.5.1 Solutions for a general equation of state

Let us first assume a general equation of state parameter for a single component, $w = p/\rho$ which is constant. In this case, Eq. (22.10) can be written as $\dot{\rho} = -3(1+w)\rho\dot{R}/R$ and is easily integrated to yield

$$\rho \propto R^{-3(1+w)}. \quad (22.16)$$

Curvature domination occurs at rather late times (if a cosmological constant term does not dominate sooner). For $w \neq -1$,

$$R(t) \propto t^{2/[3(1+w)]}. \quad (22.17)$$

22.1.5.2 A Radiation-dominated Universe

In the early hot and dense Universe, it is appropriate to assume an equation of state corresponding to a gas of radiation (or relativistic particles) for which $w = 1/3$. In this case, Eq. (22.16) becomes $\rho \propto R^{-4}$. Similarly, one can substitute $w = 1/3$ into Eq. (22.17) to obtain

$$R(t) \propto t^{1/2}; \quad H = 1/2t. \quad (22.18)$$

22.1.5.3 A Matter-dominated Universe

Non-relativistic matter eventually dominates the energy density over radiation. A pressureless gas ($w = 0$) leads to the expected dependence $\rho \propto R^{-3}$, and, if $k = 0$, we obtain

$$R(t) \propto t^{2/3}; \quad H = 2/3t. \quad (22.19)$$

22.1.5.4 A Universe dominated by vacuum energy

If there is a dominant source of vacuum energy, acting as a cosmological constant with equation of state $w = -1$. This leads to an exponential expansion of the Universe:

$$R(t) \propto e^{\sqrt{\Lambda/3}t}. \quad (22.20)$$

22.3 The Hot Thermal Universe

22.3.2 Radiation content of the Early Universe

At the very high temperatures associated with the early Universe, massive particles are pair produced, and are part of the thermal bath. If for a given particle species i we have $T \gg m_i$, then we can neglect the mass and the thermodynamic quantities are easily computed. In general, we can approximate the energy density (at high temperatures) by including only those particles with $m_i \ll T$. In this case, we have

$$\rho = \left(\sum_B g_B + \frac{7}{8} \sum_F g_F \right) \frac{\pi^2}{30} T^4 \equiv \frac{\pi^2}{30} N(T) T^4, \quad (22.42)$$

where $g_{B(F)}$ is the number of degrees of freedom of each boson (fermion) and the sum runs over all boson and fermion states with $m \ll T$. Eq. (22.42) defines the effective number of degrees of freedom, $N(T)$, by taking into account new particle degrees of freedom as the temperature is raised.

The value of $N(T)$ at any given temperature depends on the particle physics model. In the standard $SU(3) \times SU(2) \times U(1)$ model, we can specify $N(T)$ up to temperatures of $O(100)$ GeV. At higher temperatures, $N(T)$ will be model-dependent.

In the radiation-dominated epoch, Eq. (22.10) can be integrated (neglecting the T -dependence of N) giving us a relationship between the age of the Universe and its temperature

$$t = \left(\frac{90}{32\pi^3 G_N N(T)} \right)^{1/2} T^{-2}. \quad (22.43)$$

Put into a more convenient form

$$t T_{\text{MeV}}^2 = 2.4 [N(T)]^{-1/2}, \quad (22.44)$$

where t is measured in seconds and T_{MeV} in units of MeV.

27. Dark Matter

Revised August 2021 by L. Baudis (Zurich U.) and S. Profumo (UC Santa Cruz).

27.6 Laboratory detection of dark matter

Laboratory searches for DM particles can be roughly classified in direct detection experiments, axion searches, and searches at accelerators and colliders.

27.6.1 Searches at Accelerators and Colliders

Various searches for dark matter have been carried out by the CMS and ATLAS collaborations at the LHC in pp collisions [91–95]. In general, these assume that dark matter particles escape the detector without interacting leading to significant amounts of missing energy and momentum.

27.6.2 Direct detection formalism

Direct detection experiments mostly aim to observe elastic or inelastic scatters of Galactic DM particles with atomic nuclei, or with electrons in the detector material. Predicted event rates assume a certain mass and scattering cross section, as well as a set of astrophysical parameters: the local density ρ_0 , the velocity distribution $f(\vec{v})$, and the escape velocity v_{esc} (see Sec. 27.4).

Figure 27.1 shows the best constraints for SI couplings in the cross section versus DM mass parameter space, above masses of 0.3 GeV.

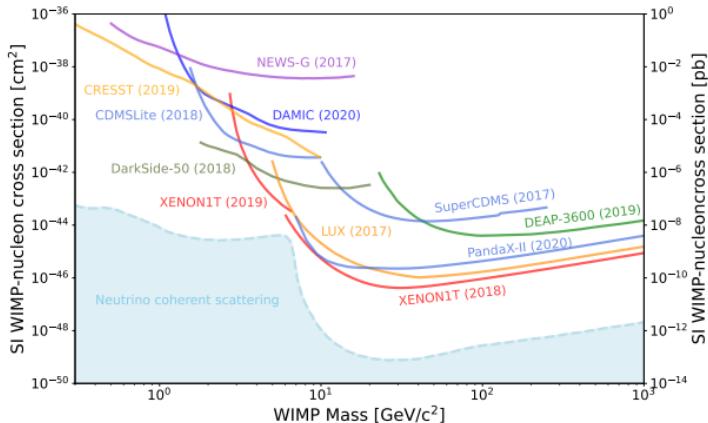

Figure 27.1: Upper limits on the SI DM-nucleon cross section as a function of DM mass.

27.7 Astrophysical detection of dark matter

DM as a microscopic constituent can have measurable, macroscopic effects on astrophysical systems. Indirect DM detection refers to the search for the annihilation or decay debris from DM particles, resulting in detectable species, including especially gamma rays, neutrinos, and antimatter particles. The production rate of such particles depends on (i) the annihilation (or decay) rate (ii) the density of pairs (respectively, of individual particles) in the region of interest, and (iii) the number of final-state particles produced in one annihilation (decay) event.

29. Cosmic Microwave Background

Revised August 2021 by D. Scott (U. of British Columbia) and G.F. Smoot (HKUST; UC Berkeley; LBNL; DIPC; Paris U.).

29.2 CMB Spectrum

It is well-known that the spectrum of the microwave background is very precisely that of blackbody radiation, whose temperature evolves with redshift as $T(z) = T_0(1 + z)$ in an expanding Universe.

29.3 Description of CMB Anisotropies

Observations show that the CMB contains temperature anisotropies at the 10^{-5} level and polarization anisotropies at the 10^{-6} (and lower) level, over a wide range of angular scales. These anisotropies are usually expressed using a spherical harmonic expansion of the CMB sky:

$$T(\theta, \phi) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\theta, \phi) \quad (29.1)$$

(with the linear polarization pattern written in a similar way using the so-called spin-2 spherical harmonics). Increasing angular resolution requires that the expansion goes to higher multipoles. Because there are only very weak phase correlations seen in the CMB sky and since we notice no preferred direction, the vast majority of the cosmological information is contained in the temperature 2-point function, *i.e.*, the variance as a function only of angular separation. Equivalently, the anisotropy power per unit $\ln \ell$ is $\ell \sum_m |a_{\ell m}|^2 / 4\pi$.

29.3.1 The Monopole

The CMB has a mean temperature of $T_\gamma = 2.7255 \pm 0.0006$ K (1σ) [19], which can be considered as the monopole component of CMB maps, a_{00} . Since all mapping experiments involve difference measurements, they are insensitive to this average level; monopole measurements can only be made with absolute temperature devices, such as the FIRAS instrument on the *COBE* satellite [20]. The measured kT_γ is equivalent to 0.234 meV or $4.60 \times 10^{-10} m_e c^2$. A blackbody of the measured temperature has a number density $n_\gamma = (2\zeta(3)/\pi^2) T_\gamma^3 \simeq 411 \text{ cm}^{-3}$, energy density $\rho_\gamma = (\pi^2/15) T_\gamma^4 \simeq 4.64 \times 10^{-34} \text{ g cm}^{-3} \simeq 0.260 \text{ eV cm}^{-3}$, and a fraction of the critical density $\Omega_\gamma \simeq 5.38 \times 10^{-5}$.

29.3.2 The Dipole

The largest anisotropy is in the $\ell = 1$ (dipole) first spherical harmonic, with amplitude 3.3621 ± 0.0010 mK [10]. The dipole is interpreted to be the result of the Doppler boosting of the monopole caused by the Solar System motion relative to the nearly isotropic blackbody field, as broadly confirmed by measurements of the radial velocities of local galaxies (*e.g.*, Ref. [21]).

29.3.3 Higher-Order Multipoles

The variations in the CMB temperature maps at higher multipoles ($\ell \geq 2$) are interpreted as being mostly the result of perturbations in the density of the early Universe, manifesting themselves at the epoch of the last scattering of the CMB photons.

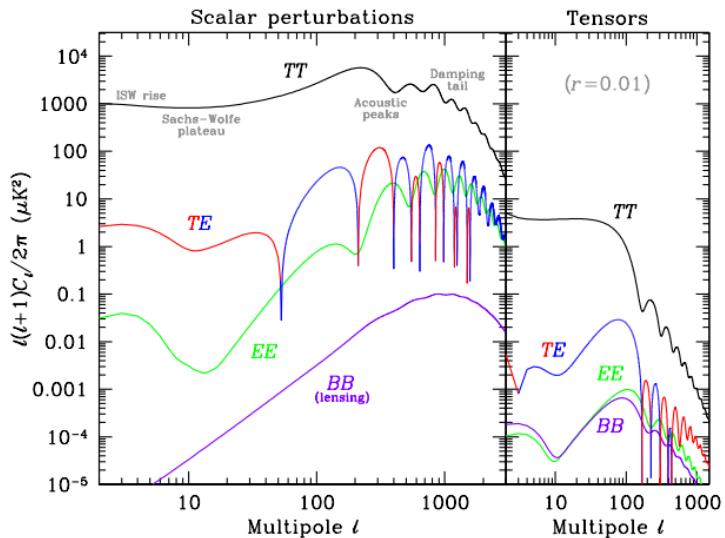

Figure 29.1: Theoretical CMB anisotropy power spectra, using the best-fitting Λ CDM model from *Planck*, calculated using *CAMB*. The panel on the left shows the theoretical expectation for scalar perturbations, while the panel on the right is for tensor perturbations, with an amplitude set to $r = 0.01$ for illustration.

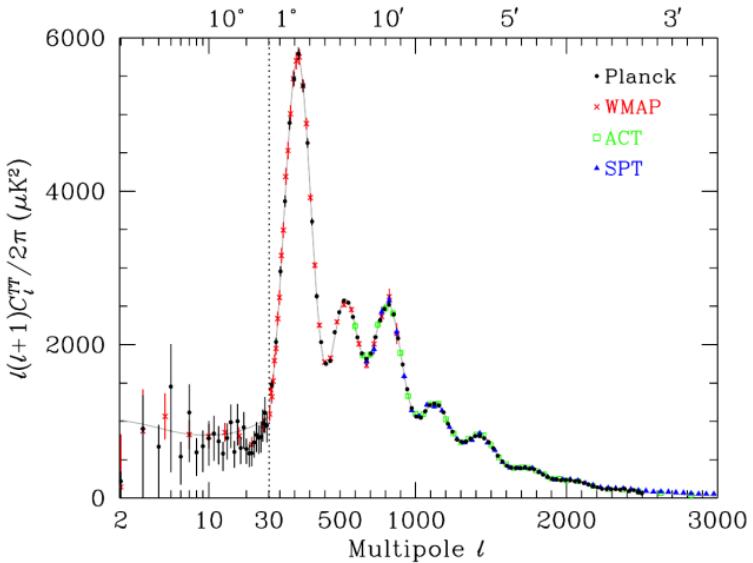

Figure 29.2: CMB temperature anisotropy band-power estimates from the *Planck*, *WMAP*, *ACT*, and *SPT* experiments. The acoustic peaks and damping region are very clearly observed, with no need for a theoretical line to guide the eye; however, the curve plotted is the best-fit *Planck* Λ CDM model.

30. Cosmic Rays

Revised October 2021 by J.J. Beatty (Ohio State U.), J. Matthews (Louisiana State U.) and S.P. Wakely (Chicago U.; Chicago U., Kavli Inst.).

Cosmic ray spectra are expressed in terms of differential intensity I with units [$\text{m}^{-2} \text{s}^{-1} \text{sr}^{-1} \mathcal{E}^{-1}$], where the unit for \mathcal{E} is chosen from energy per nucleon, energy per nucleus, and magnetic rigidity depending on the application.

Primary Cosmic Rays

The intensity of primary nucleons in the energy range from several GeV to somewhat beyond 100 TeV is given approximately by

$$I_N(E) \approx 1.8 \times 10^4 (E/1 \text{ GeV})^{-\alpha} \frac{\text{nucleons}}{\text{m}^2 \text{ s sr GeV}} \quad (30.2)$$

where E is the energy-per-nucleon (including rest mass energy) and $\alpha = 2.7$ is the differential spectral index. About 74% of the primary nucleons are free protons and about 70% of the rest are bound in helium nuclei. At higher energies, the all-particle spectrum in terms of energy per *nucleus* is used. Above a few times 10^{15} eV the spectrum steepens at the ‘knee’, again steepens at a ‘second knee’ near 10^{17} eV, and flattens at the ‘ankle’ near $10^{18.5}$ eV. Above 5×10^{19} eV the spectrum steepens rapidly due to the onset of inelastic interactions with the cosmic microwave background.

Secondary Cosmic Rays at Sea Level

Cosmic rays at sea level are mostly muons from air showers induced by primary cosmic rays. The integral intensity of vertical muons above 1 GeV/c at sea level is $\approx 70 \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1}$. The overall angular distribution of muons at the ground as a function of zenith angle θ is $\propto \cos^2 \theta$. This results in a muon rate of about $1 \text{ cm}^{-2} \text{ min}^{-1}$ for a thin horizontal detector. In addition to muons, there is a significant component of electrons and positrons with an integral vertical intensity very approximately 30, 6, and $0.2 \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1}$ above 10, 100, and 1000 MeV respectively, with a complicated angular dependence. The integral intensity of vertical protons above 1 GeV/c at sea level is $\approx 0.9 \text{ m}^{-2} \text{sr}^{-1}$, accompanied by neutrons at about 1/3 of the proton flux.

Particles in the Atmosphere and Underground

At altitudes h between 1 and 6 km above sea level the vertical flux of particles with $E > 1 \text{ GeV}$ is dominated by muons with a flux of $\approx 100 \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1} \times (h/\text{km})^{0.42}$.

The underground charged particle flux is predominantly muons. For ice or water at depth $d > 1 \text{ km}$ the vertical flux is $\approx 2.2 \times 10^{-2} \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1} \times (d/\text{km})^{-4.5}$. Below depths of $\approx 20 \text{ km}$ w.e., most remaining muons are produced by neutrino interactions. The upward-going vertical intensity of muons above 2 GeV is $\approx 2 \times 10^{-9} \text{ m}^{-2} \text{s}^{-1} \text{sr}^{-1}$. The horizontal intensity below 20 km w.e. is about twice the upward-going vertical intensity.

For details and references see the full *Review of Particle Physics*.

31. Accelerator Physics of Colliders

Revised October 2021 by V. Shiltsev (FNAL) and F. Zimmermann (CERN).

Collisions of two beams of particles accelerated to high energies $E_{1,2}$ provide access to center-of-mass energies (c.m.e.) $E_{\text{cme}} \approx 2\sqrt{E_1 E_2}$, that is twice the beam energy $E_{\text{cme}} = 2E_b$ for a typically small or zero crossing angle and equal energy beams. Particles with charge Ze gain energy $\Delta E_b = ZeGl$ from high-frequency RF electric field with the average accelerating gradient G over distance l . The highest gradients achieved to date reach $G \approx 100 \text{ MV/m}$ in 12 GHz normal-conducting RF cavities and $\sim 30 \text{ MV/m}$ in 1.3 GHz superconducting (SC) ones, allow accessing high energies over reasonably long linacs. Repeated use of smaller RF system makes circular colliders cost-effective. In the rings, the ultra-relativistic particles' momentum is determined by the field of dipole magnets B and bending radius ρ inside them, $p = ZeB\rho$ or $E_b[\text{GeV}] = 0.3Z(B\rho)$ [Tm]. The maximum field of SC magnets with Nb-Ti wires cooled to liquid He temperatures can reach over 8 T, and up to 16 T with Nb₃Sn conductor.

For the cross section of the process of interest, σ_{exp} and the instantaneous *luminosity*, \mathcal{L} , the event rate is $dN_{\text{exp}}/dt = \sigma_{\text{exp}}\mathcal{L}$. Today's colliders all employ bunched beams tightly focused at the interaction points to minimal rms transverse beam sizes σ_x^* and σ_y^* . If two of beams of n_b bunches, each containing N particles collide head-on with frequency $f_{\text{coll}} = n_b f_0$, a basic expression for the luminosity is

$$\mathcal{L} = f_{\text{coll}} \frac{N^2}{4\pi\sigma_x^*\sigma_y^*} \mathcal{F} = f_0 \gamma n_b \frac{N^2}{4\pi \sqrt{\epsilon_{nx}\beta_x^*\epsilon_{ny}\beta_y^*}} \mathcal{F}. \quad (31.15)$$

where f_0 is the revolution frequency (or repetition rate in case of linear colliders), γ is the Lorentz factor, and \mathcal{F} is a factor of order 1, that takes into account geometric beam overlap effects. The second part in Eq. (31.3) recasts the rms sizes in terms of normalized transverse emittances (adiabatic invariants) and the amplitude (*beta*-) functions β^* at the IP as $\sigma_{x,y}^* = \beta_{x,y}^* \epsilon_{nx,y}/\gamma$.

Ultimate collider luminosity calls for high beam currents $I_b = Zef_0n_bN$ resulting in growing RF demands to compensate the synchrotron-radiation (SR) power loss $P = I_b \Delta E_{\text{SR}}$ in e^+/e^- beams, the advent of *coherent beam instabilities*, and the need to minimize radiation due to inevitable particle losses. Energy and luminosity limits of high-energy circular e^+e^- colliders are mostly defined by the SR energy loss per turn $\Delta E_{\text{SR}} = 88.5 \text{ [keV/turn]} E_b^4 [\text{GeV}]/\rho [\text{m}]$, that needs to be replenished by ring's RF system. Critically important are disruptions due to electric and magnetic forces of the opposite bunch at the IPs, characterized by a dimensionless *beam-beam tuneshift parameter*

$$\xi_{x,y} = \frac{r_0 N \beta_{x,y}^*}{2\pi\gamma\sigma_{x,y}^*(\sigma_x^* + \sigma_y^*)}, \quad (31.16)$$

where $r_0 = Z^2 e^2 / (4\pi\epsilon_0 mc^2)$ is the classical radius of the colliding particle. Beam-beam limits of $\xi_{x,y} \leq 0.01$ in circular hadron and ~ 0.1 in circular e^+e^- colliders, directly affect the luminosity reach, as $\mathcal{L} \propto \xi$. The emission of beamstrahlung spreads up the c.m.e. spectra of linear e^+e^- colliders. In addition, for hadron colliders, fundamental luminosity limits are the beam lifetime due to inelastic pp interaction *burn-off* $dN/dt = -\mathcal{L}\sigma_{\text{in}}$, SR heat to be removed from inside SC magnets, and the radiation from the collision debris. Production, cooling and fast acceleration of muon beams are key challenges for future high-energy high-luminosity muon colliders.

Table: Tentative parameters of selected future high-energy colliders. Parameters associated with different beam energy scenarios are commaseparated. Quantities are, where appropriate, r.m.s.; H and V indicate horizontal and vertical directions. See full *Review* for complete tables. Parameters for other proposed high-energy colliders, including the Compact Linear Collider (CLIC), can also be found in the full *Review*.

34. Passage of Particles Through Matter

Revised August 2021 by D.E. Groom (LBNL) and S.R. Klein (NSD LBNL; UC Berkeley).

This review covers the interactions of photons and electrically charged particles in matter, concentrating on energies of interest for high-energy physics and astrophysics and processes of interest for particle detectors.

Table 34.1: Summary of variables used in this section. The kinematic variables β and γ have their usual relativistic meanings.

Symb.	Definition	Value or (usual) units
$m_e c^2$	electron mass $\times c^2$	0.510 998 950 00(15) MeV
r_e	classical electron radius $e^2/4\pi\epsilon_0 m_e c^2$	2.817 940 3227(19) fm
α	fine structure constant $e^2/4\pi\epsilon_0 \hbar c$	1/137.035 999 139(31)
N_A	Avogadro's number	6.022 140 857(74) $\times 10^{23}$ mol $^{-1}$
ρ	density	g cm $^{-3}$
x	mass per unit area	g cm $^{-2}$
M	incident particle mass	MeV/c 2
E	incident part. energy $\gamma M c^2$	MeV
T	kinetic energy, $(\gamma - 1) M c^2$	MeV
W	energy transfer to an electron in a single collision	MeV
W_{\max}	Maximum possible energy transfer to an electron in a single collision	MeV
k	bremsstrahlung photon energy	MeV
z	charge number of incident particle	
Z	atomic number of absorber	
A	atomic mass of absorber	g mol $^{-1}$
K	$4\pi N_A r_e^2 m_e c^2$ (Coefficient for dE/dx)	0.307 075 MeV mol $^{-1}$ cm 2
I	mean excitation energy	eV (<i>Nota bene!</i>)
$\delta(\beta\gamma)$	density effect correction to ionization energy loss	
$\hbar\omega_p$	plasma energy $\sqrt{4\pi N_e r_e^3 m_e c^2/\alpha}$	$\sqrt{\rho(Z/A)} \times 28.816$ eV $\downarrow \rho$ in g cm $^{-3}$
N_e	electron density	(units of r_e) $^{-3}$
w_j	weight fraction of the j th element in a compound or mixt.	
n_j	\propto number of j th kind of atoms in a compound or mixture	
X_0	radiation length	g cm $^{-2}$
E_c	critical energy for electrons	MeV
$E_{\mu c}$	critical energy for muons	GeV
E_s	scale energy $\sqrt{4\pi/\alpha} m_e c^2$	21.2052 MeV
R_M	Molière radius	g cm $^{-2}$

34.2.2 Maximum energy transfer in a single collision

For a particle with mass M ,

$$W_{\max} = \frac{2m_e c^2 \beta^2 \gamma^2}{1 + 2\gamma m_e/M + (m_e/M)^2}. \quad (34.4)$$

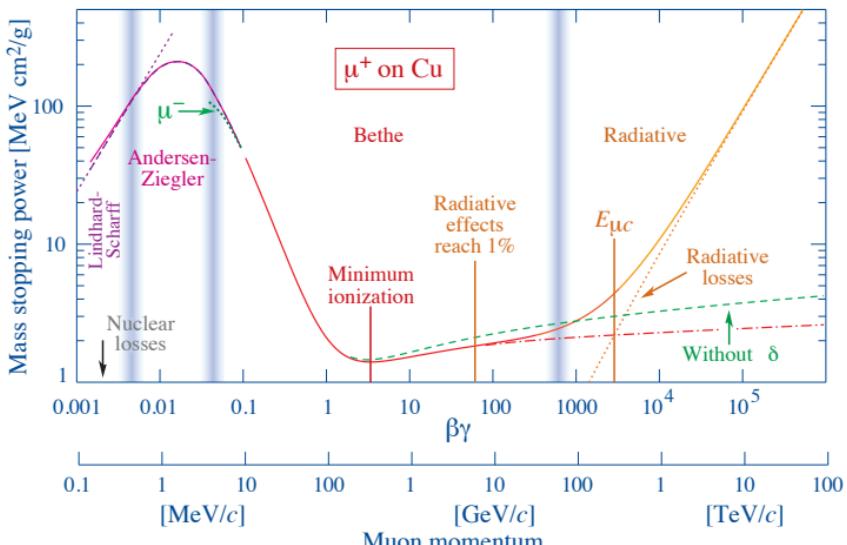

Figure 34.1: Mass stopping power ($= \langle -dE/dx \rangle$) for positive muons in copper as a function of $\beta\gamma = p/Mc$ over nine orders of magnitude in momentum (12 orders of magnitude in kinetic energy). Vertical bands indicate boundaries between different approximations discussed in the text.

34.2.3 Stopping power at intermediate energies

The mean rate of energy loss by moderately relativistic charged heavy particles is well-described by the “Bethe equation,”

$$\left\langle -\frac{dE}{dx} \right\rangle = K z^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 W_{\max}}{I^2} - \beta^2 - \frac{\delta(\beta\gamma)}{2} \right]. \quad (34.5)$$

This is the *mass stopping power*; with the symbol definitions and values given in Table 34.1, the units are $\text{MeV g}^{-1}\text{cm}^2$. As can be seen from Fig. 34.2, $\langle -dE/dx \rangle$ defined in this way is about the same for most materials, decreasing slowly with Z . The *linear stopping power*, in MeV/cm , is $\langle -dE/dx \rangle \rho$, where ρ is the density in g/cm^3 .

As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (34.5) increases as $\ln \beta\gamma$. However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic rise. Parameterization of the density effect term $\delta(\beta\gamma)$ in Eq. (34.5) is discussed in the full *Review*.

Few concepts in high-energy physics are as misused as $\langle dE/dx \rangle$. The mean is weighted by very rare events with large single-collision energy deposits. Even with samples of hundreds of events a dependable value for the mean energy loss cannot be obtained. Far better and more easily measured is the most probable energy loss, discussed below.

Although it must be used with cautions and caveats, $\langle dE/dx \rangle$ as described in Eq. (34.5) still forms the basis of much of our understanding of energy loss by charged particles. Extensive tables are available [pdg.lbl.gov/AtomicNuclearProperties/].

Eq. (34.5) may be integrated to find the total (or partial) “continuous slowing-down approximation” (CSDA) range R . Since dE/dx depends (nearly) only on β , R/M is a function of E/M or pc/M .

34.2.9 Fluctuations in energy loss

For detectors of moderate thickness x (*e.g.* scintillators or LAr cells), the energy loss probability distribution $f(\Delta; \beta\gamma, x)$ is adequately described by the highly-skewed Landau (or Landau-Vavilov) distribution [30] [29]. The most probable energy loss

$$\Delta_p = \xi \left[\ln \frac{2mc^2\beta^2\gamma^2}{I} + \ln \frac{\xi}{I} + j - \beta^2 - \delta(\beta\gamma) \right], \quad (34.12)$$

where $\xi = (K/2) \langle Z/A \rangle z^2(x/\beta^2)$ MeV for a detector with a thickness x in g cm⁻², and $j = 0.200$ [31]. While dE/dx is independent of thickness, Δ_p/x scales as $a \ln x + b$. This most probable energy loss reaches a (Fermi) plateau rather than continuing $\langle dE/dx \rangle$'s logarithmic rise with increasing energy.

34.4 Photon and electron interactions in matter

At low energies electrons and positrons primarily lose energy by ionization, although other processes (Møller scattering, Bhabha scattering, e^+ annihilation) contribute. While ionization loss rates rise logarithmically with energy, bremsstrahlung losses rise nearly linearly (fractional loss is nearly independent of energy), and dominates above the critical energy (Sec. 34.4.4 below), a few tens of MeV in most materials.

34.4.1 Collision energy losses by e^\pm

Stopping power differs somewhat for electrons and positrons, and both differ from stopping power for heavy particles because of the kinematics, spin, charge, and the identity of the incident electron with the electrons that it ionizes. Complete discussions and tables can be found in Refs. [12, 15], and [34] in the full *Review*.

34.4.2 Radiation length

High-energy electrons predominantly lose energy in matter by bremsstrahlung, and high-energy photons by e^+e^- pair production. The characteristic amount of matter traversed for these related interactions is called the radiation length X_0 , usually measured in g cm⁻². X_0 has been calculated and tabulated by Y.S. Tsai [42]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A} \left\{ Z^2 [L_{\text{rad}} - f(Z)] + Z L'_{\text{rad}} \right\}. \quad (34.25)$$

For $A = 1$ g mol⁻¹, $4\alpha r_e^2 N_A / A = (716.408 \text{ g cm}^{-2})^{-1}$. L_{rad} and L'_{rad} are tabulated in the full *Review*, where a 4-place approximation for $f(z)$ is also given.

34.4.3 Bremsstrahlung energy loss by e^\pm

At very high energies and except at the high-energy tip of the bremsstrahlung spectrum, the cross section can be approximated in the “complete screening case” as [42]

$$d\sigma/dk = (1/k) 4\alpha r_e^2 \left\{ \left(\frac{4}{3} - \frac{4}{3}y + y^2 \right) [Z^2 (L_{\text{rad}} - f(Z)) + Z L'_{\text{rad}}] + \frac{1}{9}(1-y)(Z^2 + Z) \right\}, \quad (34.28)$$

where $y = k/E$ is the fraction of the electron’s energy transferred to the radiated photon. At small y (the “infrared limit”) the term on the second line ranges from 1.7% (low Z) to 2.5% (high Z) of the total. If it

is ignored and the first line simplified with the definition of X_0 given in Eq. (34.25), we have

$$\frac{d\sigma}{dk} = \frac{A}{X_0 N_A k} \left(\frac{4}{3} - \frac{4}{3}y + y^2 \right) . \quad (34.29)$$

34.4.4 Critical energy

An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The *critical energy* E_c is sometimes defined as the energy at which the two loss rates are equal [49]. Among alternate definitions is that of Rossi [2], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation $|dE/dx|_{\text{brems}} \approx E/X_0$. This form has been found to describe transverse electromagnetic shower development more accurately.

Values of E_c for electrons can be reasonably well described by $(610 \text{ MeV})/(Z + 1.24)$ for solids and $(710 \text{ MeV})/(Z + 0.92)$ for gases. E_c for both electrons and positrons in more than 350 materials can be found at pdg.lbl.gov/AtomicNuclearProperties.

34.4.5 Energy loss by photons

At low energies the photoelectric effect dominates, although Compton scattering, Rayleigh scattering, and photonuclear absorption also contribute. The photoelectric cross section is characterized by discontinuities (absorption edges) as thresholds for photoionization of various atomic levels are reached. Pair production dominates at high energies, but is suppressed at ultrahigh energies because of quantum mechanical interference between amplitudes from different scattering centers (LPM effect).

At still higher photon and electron energies, where the bremsstrahlung and pair production cross-sections are heavily suppressed by the LPM effect, photonuclear and electronuclear interactions predominate over electromagnetic interactions. At photon energies above about 10^{20} eV , for example, photons usually interact hadronically.

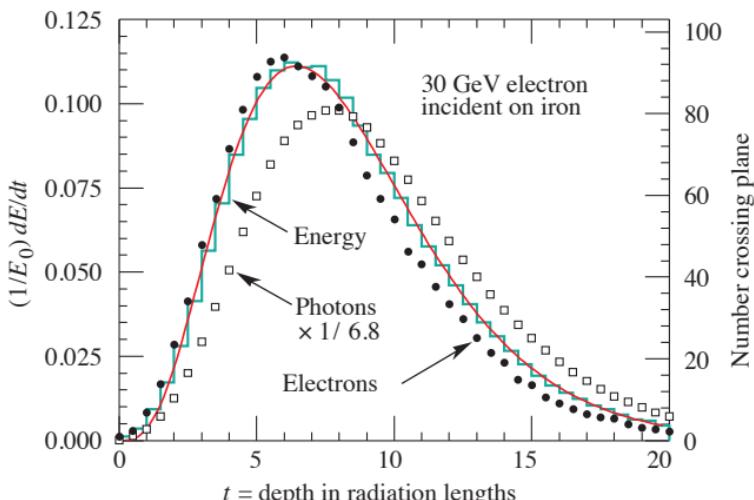

Figure 34.20: An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution.

34.5 Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energies.

The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is convenient to introduce the scale variables

$$t = x/X_0, \quad y = E/E_c, \quad (34.34)$$

so that distance is measured in units of radiation length and energy in units of critical energy.

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [61]:

$$\frac{dE}{dt} = E_0 b \frac{(bt)^{a-1} e^{-bt}}{\Gamma(a)} \quad (34.35)$$

at energies from 1 GeV to 100 GeV.

34.6 Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. These contributions increase almost linearly with energy. It is convenient to write the average rate of muon energy loss as [74]

$$-dE/dx = a(E) + b(E) E. \quad (34.39)$$

Here $a(E)$ is the ionization energy loss given by Eq. (34.5), and $b(E) E$ is the sum of e^+e^- pair production, bremsstrahlung, and photonuclear contributions. These are subject large fluctuations, particularly at higher energies.

To the approximation that the slowly-varying functions $a(E)$ and $b(E)$ are constant, the mean range x_0 of a muon with initial energy E_0 is given by

$$x_0 \approx (1/b) \ln(1 + E_0/E_{\mu c}), \quad (34.40)$$

where $E_{\mu c} = a/b$.

The "muon critical energy" $E_{\mu c}$ can be defined as the energy at which radiative and ionization losses are equal, and can be found by solving $E_{\mu c} = a(E_{\mu c})/b(E_{\mu c})$. This definition is different from the Rossi definition we used for electrons. It decreases with Z , and is several hundred GeV for iron. It is given for the elements and many other materials in pdg.lbl.gov/AtomicNuclearProperties.

34.7 Cherenkov and transition radiation

A charged particle radiates if its velocity is greater than the local phase velocity of light (Cherenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy and cosmic-ray physics detectors.

34.7.1 Optical Cherenkov radiation

The angle θ_c of Cherenkov radiation, relative to the particle's direction, for a particle with velocity βc in a medium with index of refraction n is

$$\begin{aligned}\cos \theta_c &= (1/n\beta) \\ \text{or } \tan \theta_c &= \sqrt{\beta^2 n^2 - 1} \\ &\approx \sqrt{2(1 - 1/n\beta)} \quad \text{for small } \theta_c, \text{ e.g. in gases.}\end{aligned}\quad (34.41)$$

The threshold velocity β_t is $1/n$. Values of $n - 1$ for various commonly used gases are given as a function of pressure and wavelength in Ref. [80]. Data for other commonly used materials are given in [81].

The number of photons produced per unit path length of a particle with charge ze and per unit energy interval of the photons is

$$\begin{aligned}\frac{d^2N}{dEdx} &= \frac{\alpha z^2}{\hbar c} \sin^2 \theta_c = \frac{\alpha^2 z^2}{r_e m_e c^2} \left(1 - \frac{1}{\beta^2 n^2(E)}\right) \\ &\approx 370 \sin^2 \theta_c(E) \text{ eV}^{-1} \text{cm}^{-1} \quad (z = 1),\end{aligned}\quad (34.43)$$

or, equivalently,

$$\frac{d^2N}{dxd\lambda} = \frac{2\pi\alpha z^2}{\lambda^2} \left(1 - \frac{1}{\beta^2 n^2(\lambda)}\right). \quad (34.44)$$

34.7.2 Coherent radio Cherenkov radiation

Coherent Cherenkov radiation is produced by many charged particles with a non-zero net charge moving through matter on an approximately common “wavefront”—for example, the electrons and positrons in a high-energy electromagnetic cascade. Near the end of a shower, when typical particle energies are below E_c (but still relativistic), a charge imbalance develops. Photons can Compton-scatter atomic electrons, and positrons can annihilate with atomic electrons to contribute even more photons which can in turn Compton scatter. These processes result in a roughly 20% excess of electrons over positrons in a shower. The net negative charge leads to coherent radio Cherenkov emission. The phenomenon is called the Askaryan effect [86]. The signals can be visible above backgrounds for shower energies as low as 10^{17} eV; see Sec. 36.3.3 for more details.

34.7.3 Transition radiation

The energy radiated when a particle with charge ze crosses the boundary between vacuum and a medium with plasma frequency ω_p is

$$I = \alpha z^2 \gamma \hbar \omega_p / 3, \quad (34.45)$$

The plasma energy $\hbar \omega_p$ is defined in Table 34.1.

For styrene and similar materials, $\hbar \omega_p \approx 20$ eV; for air it is 0.7 eV. The number spectrum $dN_\gamma/d(\hbar\omega)$ diverges logarithmically at low energies and decreases rapidly for $\hbar\omega/\gamma\hbar\omega_p > 1$. Inevitable absorption in a practical detector removes the divergence. About half the energy is emitted in the range $0.1 \leq \hbar\omega/\gamma\hbar\omega_p \leq 1$. The γ dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a particle with $\gamma = 10^3$, the radiated photons are in the soft x-ray range 2 to 40 keV.

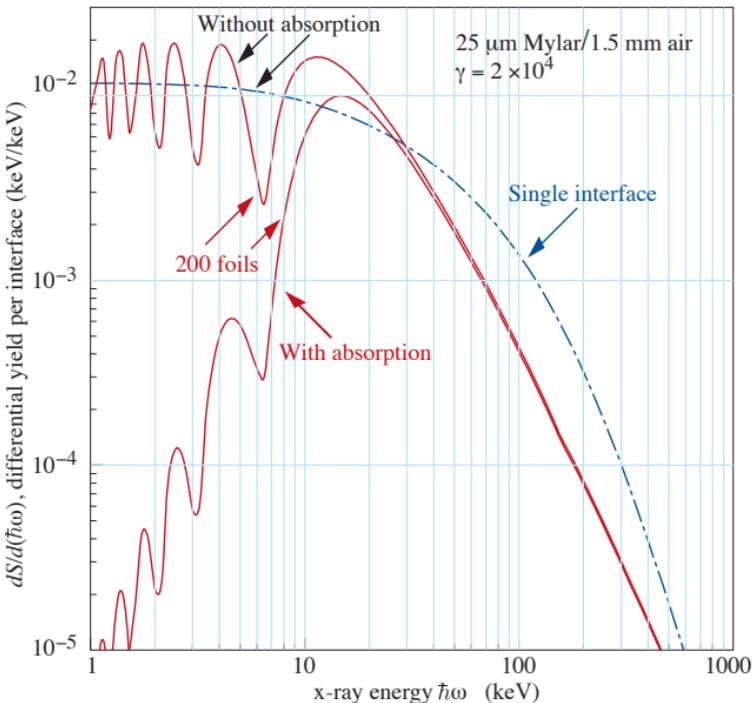

Figure 34.27: X-ray photon energy spectra for a radiator consisting of 200 $25 \mu\text{m}$ thick foils of Mylar with 1.5 mm spacing in air (solid lines) and for a single surface (dashed line).

The number of photons with energy $\hbar\omega > \hbar\omega_0$ is given by the answer to problem 13.15 in [3],

$$N_\gamma(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi} \left[\left(\ln \frac{\gamma \hbar\omega_p}{\hbar\omega_0} - 1 \right)^2 + \frac{\pi^2}{12} \right], \quad (34.47)$$

within corrections of order $(\hbar\omega_0/\gamma \hbar\omega_p)^2$. The number of photons above a fixed energy $\hbar\omega_0 \ll \gamma \hbar\omega_p$ thus grows as $(\ln \gamma)^2$, but the number above a fixed fraction of $\gamma \hbar\omega_p$ (as in the example above) is constant. For example, for $\hbar\omega > \gamma \hbar\omega_p/10$, $N_\gamma = 2.519 \alpha z^2 / \pi = 0.0059 \times z^2$.

The particle stays “in phase” with the x ray over a distance called the formation length, $d(\omega) = (2c/\omega)(1/\gamma^2 + \theta^2 + \omega_p^2/\omega^2)^{-1}$. Most of the radiation is produced in this distance. Here θ is the x-ray emission angle, characteristically $1/\gamma$. For $\theta = 1/\gamma$ the formation length has a maximum at $d(\gamma \omega_p / \sqrt{2}) = \gamma c / \sqrt{2} \omega_p$. In practical situations it is tens of μm .

Since the useful x-ray yield from a single interface is low, in practical detectors it is enhanced by using a stack of N foil radiators—foils L thick, where L is typically several formation lengths—separated by gas-filled gaps. The amplitudes at successive interfaces interfere to cause oscillations about the single-interface spectrum. At increasing frequencies above the position of the last interference maximum ($L/d(\omega) = \pi/2$), the formation zones, which have opposite phase, overlap more and more and the spectrum saturates, $dI/d\omega$ approaching zero as $L/d(\omega) \rightarrow 0$. This is illustrated in Fig. 34.27 for a realistic detector configuration.

Although one might expect the intensity of coherent radiation from the stack of foils to be proportional to N^2 , the angular dependence of the formation length conspires to make the intensity $\propto N$.

35. Particle Detectors at Accelerators

Revised 2021. See the various sections for authors.

35.1 Introduction

This review summarizes the detector technologies employed at accelerator particle physics experiments. Several of these detectors are also used in a non-accelerator context and examples of such applications will be provided. The detector techniques which are specific to non-accelerator particle physics experiments are the subject of Chap. 36. More detailed discussions of detectors and their underlying physics can be found in books by Kolanoski & Wermes [1], Ferbel [2], Kleinknecht [3], Knoll [4], Green [5], Leroy & Ranchoita [6], and Grupen [7].

In Table 35.1 are given typical resolutions and deadtimes of common charged particle detectors. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. The spatial resolution refers to the intrinsic detector resolution, i.e. without multiple scattering. We note that analog detector readout can provide better spatial resolution than digital readout by measuring and averaging the deposited charge in neighboring channels. Quoted ranges attempt to be representative of both possibilities. The time resolution is defined by how accurately the time at which a particle crossed the detector can be determined. The deadtime is the minimum separation in time between two resolved hits on the same channel. Typical performance of calorimetry and particle identification are provided in the relevant sections below. Further discussion and all references may be found in the full *Review*.

Table 35.1: Typical resolutions and deadtimes of common charged particle detectors. Revised November 2021.

Detector Type	Intrinsic Spatial Resolution (rms)	Time Resolution	Dead Time
Resistive plate chamber	50 μm	50–1000 ps*	10 ns†
Liquid argon TPC	0.5–1 mm‡	0.01–1 μs§	—¶
Scintillation tracker	~100 μm	100 ps/n	10 ns
Bubble chamber	10–150 μm	1 ms	50 ms**
Wire chambers (proportional and drift chambers)	50–100 μm	5–10 ns††	2–200 ns††
Micro-pattern gas detect.	30–40 μm	5–10 ns††	2–200 ns††
Silicon strips/pixels	≤ 10 μm§§	few ns¶¶ ‡‡	≤ 50 ns††

* LHC: ~ 2mm gap, ~1ns. HL-LHC: ~ 1mm gap, ~350ps. Timing RPC: ~50ps

† Limited by amplifier and discriminator bandwidth, usually around 100MHz

‡ Detector geometry dependent

§ Using the scintillation signal

¶ No deadtime for medium

|| n = index of refraction.

** Multiple pulsing time.

†† For fast particles

‡‡ Depending/limited by the amplifying electronics [8]

§§ Depending on electrode pitch, best values around 2–4 μm have been achieved

¶¶ Resolutions < 100 ps are reached in dedicated pixel developments

37. Radioactivity and Radiation Protection

Revised August 2021 by S. Roesler (CERN) and M. Silari (CERN).

37.1 Definitions

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

- **Activity** (unit: Becquerel):

$$1 \text{ Bq} = 1 \text{ disintegration per second} (= 27 \text{ pCi}).$$

- **Absorbed dose** (unit: gray): The absorbed dose is the energy imparted by ionizing radiation in a volume element of a specified material divided by the mass of this volume element.

$$1 \text{ Gy} = 1 \text{ J/kg} (= 10^4 \text{ erg/g} = 100 \text{ rad})$$

$$= 6.24 \times 10^{12} \text{ MeV/kg deposited energy.}$$

- **Kerma** (unit: gray): Kerma is the sum of the initial kinetic energies of all charged particles liberated by indirectly ionizing particles in a volume element of the specified material divided by the mass of this volume element.

- **Exposure** (unit: C/kg of air [= 3880 Roentgen*]): The exposure is a measure of photon fluence at a certain point in space integrated over time, in terms of ion charge of either sign produced by secondary electrons in a small volume of air about the point. Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving (so-called charged particle equilibrium).

Table 37.1: Radiation weighting factors, w_R .

Radiation type	w_R
Photons	1
Electrons and muons	1
Neutrons, $E_n < 1 \text{ MeV}$	$2.5 + 18.2 \times \exp[-(\ln E_n)^2/6]$
$1 \text{ MeV} \leq E_n \leq 50 \text{ MeV}$	$5.0 + 17.0 \times \exp[-(\ln(2E_n))^2/6]$
$E_n > 50 \text{ MeV}$	$2.5 + 3.25 \times \exp[-(\ln(0.04E_n))^2/6]$
Protons and charged pions	2
Alpha particles, fission fragments, heavy ions	20

- **Equivalent dose** (unit: Sievert [= 100 rem (roentgen equivalent in man)]): The equivalent dose H_T in an organ or tissue T is equal to the sum of the absorbed doses $D_{T,R}$ in the organ or tissue caused by different radiation types R weighted with so-called radiation weighting factors w_R :

$$H_T = \sum_R w_R \times D_{T,R} .$$

It expresses long-term risks (primarily cancer and leukemia) from low-level chronic exposure. The values for w_R recommended recently by ICRP [2] are given in Table 37.1.

- **Effective dose** (unit: Sievert): The sum of the equivalent doses, weighted by the tissue weighting factors w_T ($\sum_T w_T = 1$) of several

*This unit is somewhat historical, but appears on some measuring instruments. One R is the amount of radiation required to liberate positive and negative charges of one electrostatic unit of charge in 1 cm^3 of air at standard temperature and pressure (STP)

organs and tissues T of the body that are considered to be most sensitive [2], is called “effective dose” E :

$$E = \sum_T w_T \times H_T .$$

37.2 Radiation levels [5]

- **Natural annual background**, all sources: Most world areas, whole-body equivalent dose rate $\approx (1.0\text{--}13)$ mSv (0.1–1.3 rem). Can range up to 50 mSv (5 rem) in certain areas. U.S. average ≈ 3.6 mSv, including ≈ 2 mSv (≈ 200 mrem) from inhaled natural radioactivity, mostly radon and radon daughters. (Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines. 0.1–0.2 mSv in open areas.)
- **Cosmic ray background** (sea level, mostly muons):
 $\approx 1 \text{ min}^{-1} \text{ cm}^{-2} \text{ sr}^{-1}$. For more accurate estimates and details, see the Cosmic Rays section (Sec. 30 of this *Review*).
- **Fluence** (per cm^2) to deposit one Gy, assuming uniform irradiation:
 $\approx (\text{charged particles}) 6.24 \times 10^9 / (dE/dx)$, where dE/dx ($\text{MeV g}^{-1} \text{ cm}^2$), the energy loss per unit length, may be obtained from Figs. 34.2 and 34.4 in Sec. 34 of this *Review*.
 $\approx 3.5 \times 10^9 \text{ cm}^{-2}$ minimum-ionizing singly-charged particles in carbon.
 $\approx (\text{photons}) 6.24 \times 10^9 / [Ef/\ell]$, for photons of energy E (MeV), attenuation length ℓ (g cm^{-2}), and fraction $f \leq 1$ expressing the fraction of the photon’s energy deposited in a small volume of thickness $\ll \ell$ but large enough to contain the secondary electrons.
 $\approx 2 \times 10^{11} \text{ photons cm}^{-2}$ for 1 MeV photons on carbon ($f \approx 1/2$).

37.3 Health effects of ionizing radiation

- Recommended limits of effective dose to radiation workers (whole-body dose):[†]

EU/Switzerland: 20 mSv yr^{-1}

U.S.: 50 mSv yr^{-1} (5 rem yr^{-1})[‡]

- **Lethal dose:** The whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) is 2.5–4.5 Gy (250–450 rad), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

- **Cancer induction by low LET radiation:** The cancer induction probability is about 5% per Sv on average for the entire population [3].

See full *Review* for references and further details.

[†]The ICRP recommendation [3] is 20 mSv yr^{-1} averaged over 5 years, with the dose in any one year ≤ 50 mSv.

[‡]Many laboratories in the U.S. and elsewhere set lower limits.

38. Commonly Used Radioactive Sources

Table 38.1: Radioactive sources

“Emission probability” is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and e^- means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV e^+e^- annihilation photons depends upon the number of stopped positrons. Endpoint β^\pm energies are listed. In some cases when energies are closely spaced, the γ -ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities may be found in www-pub.iaea.org/books/IAEABooks/7551/Update-of-X-Ray-and-Gamma-Ray-Decay-Data-Standards-for-Detector-Calibration-and-Other-Applications, IAEA (2007) or Nuclear Data Sheets www.journals.elsevier.com/nuclear-data-sheets (2007).

Neutron sources: See *e.g.* “Neutron Calibration Sources in the Daya Bay Experiment,” J. Liu *et al.*, Nuclear Instrum. Methods **A797**, 260 (2005) ([arXiv.1504.07911](https://arxiv.org/abs/1504.07911)).

$^{51}_{24}\text{Cr}$ calibration of neutrino detectors is discussed in *e.g.* J.N. Abdurashitov *et al.* [SAGE Collaboration], Phys. Rev. **C59**, 2246 (1999). The use of $^{75}_{34}\text{Se}$ and other isotopes has also been proposed.

39. Probability

Revised November 2021 by G. Cowan (RHUL).

The following is a much-shortened version of Sec. 39 of the full *Review*. Equation, section, and figure numbers follow the *Review*.

39.2 Random variables

- *Probability density function* (p.d.f.): x is a *random variable*.

Continuous: $f(x; \theta)dx$ = probability x is between x to $x + dx$, given parameter(s) θ ;

Discrete: $f(x; \theta)$ = probability of x given θ .

- *Cumulative distribution function*:

$$F(a) = \int_{-\infty}^a f(x) dx. \quad (39.6)$$

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is included in the integral or sum.

- *Expectation values*: Given a function u :

$$E[u(x)] = \int_{-\infty}^{\infty} u(x) f(x) dx. \quad (39.7)$$

- *Moments*:

$$n^{th} \text{ moment of a random variable: } \alpha_n = E[x^n], \quad (39.8a)$$

$$n^{th} \text{ central moment: } m_n = E[(x - \alpha_1)^n]. \quad (39.8b)$$

$$\text{Mean: } \mu \equiv \alpha_1, \quad (39.9a)$$

$$\text{Variance: } \sigma^2 \equiv V[x] \equiv m_2 = \alpha_2 - \mu^2. \quad (39.9b)$$

Coefficient of skewness: $\gamma_1 \equiv m_3/\sigma^3$.

Kurtosis: $\gamma_2 = m_4/\sigma^4 - 3$.

Median: $F(x_{\text{med}}) = 1/2$.

- *Marginal p.d.f.*: Let x, y be two random variables with joint p.d.f. $f(x, y)$.

$$f_1(x) = \int_{-\infty}^{\infty} f(x, y) dy; \quad f_2(y) = \int_{-\infty}^{\infty} f(x, y) dx. \quad (39.10)$$

- *Conditional p.d.f.*:

$$f_4(x|y) = f(x, y)/f_2(y); \quad f_3(y|x) = f(x, y)/f_1(x).$$

- *Bayes' theorem*:

$$f_4(x|y) = \frac{f_3(y|x)f_1(x)}{f_2(y)} = \frac{f_3(y|x)f_1(x)}{\int f_3(y|x')f_1(x') dx'} . \quad (39.11)$$

- Correlation coefficient and covariance:

$$\mu_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} xf(x, y) dx dy, \quad (39.12)$$

$$\rho_{xy} = E[(x - \mu_x)(y - \mu_y)] / \sigma_x \sigma_y \equiv \text{cov}[x, y] / \sigma_x \sigma_y,$$

$$\sigma_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \mu_x)^2 f(x, y) dx dy. \text{ Note } \rho_{xy}^2 \leq 1.$$

• *Independence:* x, y are independent if and only if $f(x, y) = f_1(x) \cdot f_2(y)$; then $\rho_{xy} = 0$, $E[u(x)v(y)] = E[u(x)]E[v(y)]$ and $V[x+y] = V[x] + V[y]$.

• *Change of variables:* From $\mathbf{x} = (x_1, \dots, x_n)$ to $\mathbf{x} = (y_1, \dots, y_n)$: $g(\mathbf{y}) = f(\mathbf{x}(\mathbf{y})) \cdot |J|$ where $|J|$ is the absolute value of the determinant of the Jacobian $J_{ij} = \partial x_i / \partial y_j$. For discrete variables, use $|J| = 1$.

39.3 Characteristic functions

Given a pdf $f(x)$ for a continuous random variable x , the characteristic function $\phi(u)$ is given by (31.6). Its derivatives are related to the algebraic moments of x by (31.7).

$$\phi(u) = E[e^{iux}] = \int_{-\infty}^{\infty} e^{iux} f(x) dx. \quad (39.19)$$

$$i^{-n} \left. \frac{d^n \phi}{du^n} \right|_{u=0} = \int_{-\infty}^{\infty} x^n f(x) dx = \alpha_n. \quad (39.20)$$

If the p.d.f.s $f_1(x)$ and $f_2(y)$ for independent random variables x and y have characteristic functions $\phi_1(u)$ and $\phi_2(u)$, then the characteristic function of the weighted sum $ax + by$ is $\phi_1(au)\phi_2(bu)$. The additional rules for several important distributions (e.g., that the sum of two Gaussian distributed variables also follows a Gaussian distribution) easily follow from this observation.

39.4 Some probability distributions

See Table 39.1.

39.4.2 Poisson distribution

The Poisson distribution $f(n; \nu)$ gives the probability of finding exactly n events in a given interval of x (e.g., space or time) when the events occur independently of one another and of x at an average rate of ν per the given interval. The variance σ^2 equals ν . It is the limiting case $p \rightarrow 0$, $N \rightarrow \infty$, $Np = \nu$ of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large ν .

39.4.3 Normal or Gaussian distribution

Its cumulative distribution, for mean 0 and variance 1, is often tabulated as the *error function*

$$F(x; 0, 1) = \frac{1}{2} [1 + \text{erf}(x/\sqrt{2})]. \quad (39.26)$$

For mean μ and variance σ^2 , replace x by $(x - \mu)/\sigma$.

$P(x \text{ in range } \mu \pm \sigma) = 0.6827$,

$P(x \text{ in range } \mu \pm 0.6745\sigma) = 0.5$,

$E[|x - \mu|] = \sqrt{2/\pi}\sigma = 0.7979\sigma$,

half-width at half maximum = $\sqrt{2 \ln 2} \cdot \sigma = 1.177\sigma$.

For n Gaussian random variables x_i , the joint p.d.f. is the multivariate Gaussian:

$$f(\mathbf{x}; \boldsymbol{\mu}, V) = \frac{1}{(2\pi)^{n/2} \sqrt{|V|}} \exp \left[-\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^T V^{-1} (\mathbf{x} - \boldsymbol{\mu}) \right], \quad |V| > 0. \quad (39.27)$$

V is the $n \times n$ covariance matrix; $V_{ij} \equiv E[(x_i - \mu_i)(x_j - \mu_j)] \equiv \rho_{ij} \sigma_i \sigma_j$, and $V_{ii} = V[x_i]$; $|V|$ is the determinant of V . For $n = 2$, $f(\mathbf{x}; \boldsymbol{\mu}, V)$ is

$$f(x_1, x_2; \mu_1, \mu_2, \sigma_1, \sigma_2, \rho) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \times \exp \left\{ \frac{-1}{2(1-\rho^2)} \left[\frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2} \right] \right\}. \quad (39.28)$$

The marginal distribution of any x_i is a Gaussian with mean μ_i and variance V_{ii} . V is $n \times n$, symmetric, and positive definite. Therefore for any vector \mathbf{X} , the quadratic form $\mathbf{X}^T V^{-1} \mathbf{X} = C$, where C is any positive number, traces an n -dimensional ellipsoid as \mathbf{X} varies. If $X_i = x_i - \mu_i$, then C is a random variable obeying the χ^2 distribution with n degrees of freedom, discussed in the following section. The probability that \mathbf{X} corresponding to a set of Gaussian random variables x_i lies outside the ellipsoid characterized by a given value of C ($= \chi^2$) is given by $1 - F_{\chi^2}(C; n)$, where F_{χ^2} is the cumulative χ^2 distribution. This may be read from Fig. 40.1. For example, the “ s -standard-deviation ellipsoid” occurs at $C = s^2$. For the two-variable case ($n = 2$), the point \mathbf{X} lies outside the one-standard-deviation ellipsoid with 61% probability. The use of these ellipsoids as indicators of probable error is described in Sec. 40.4.2.2; the validity of those indicators assumes that $\boldsymbol{\mu}$ and V are correct.

39.4.5 χ^2 distribution

If x_1, \dots, x_n are independent Gaussian random variables, the sum $z = \sum_{i=1}^n (x_i - \mu_i)^2 / \sigma_i^2$ follows the χ^2 p.d.f. with n degrees of freedom, which we denote by $\chi^2(n)$. More generally, for n correlated Gaussian variables as components of a vector \mathbf{X} with covariance matrix V , $z = \mathbf{X}^T V^{-1} \mathbf{X}$ follows $\chi^2(n)$ as in the previous section. For a set of z_i , each of which follows $\chi^2(n_i)$, $\sum z_i$ follows $\chi^2(\sum n_i)$. For large n , the χ^2 p.d.f. approaches a Gaussian with mean $\mu = n$ and variance $\sigma^2 = 2n$. The χ^2 p.d.f. is often used in evaluating the level of compatibility between observed data and a hypothesis for the p.d.f. that the data might follow. This is discussed further in Sec. 40.3.2 on tests of goodness-of-fit.

39.4.7 Gamma distribution

For a process that generates events as a function of x (e.g., space or time) according to a Poisson distribution, the distance in x from an arbitrary starting point (which may be some particular event) to the k^{th} event follows a gamma distribution, $f(x; \lambda, k)$. The Poisson parameter μ is λ per unit x . The special case $k = 1$ (i.e., $f(x; \lambda, 1) = \lambda e^{-\lambda x}$) is called the exponential distribution. A sum of k' exponential random variables x_i is distributed as $f(\sum x_i; \lambda, k')$.

The parameter k is not required to be an integer. For $\lambda = 1/2$ and $k = n/2$, the gamma distribution reduces to the $\chi^2(n)$ distribution.

See the full *Review* for further discussion and all references.

Table 39.1: Some common probability density functions, with corresponding characteristic functions and means and variances. In the Table, $\Gamma(k)$ is the gamma function, equal to $(k-1)!$ when k is an integer.

Distribution	Probability density function f (variable; parameters)	Characteristic function $\phi(u)$	Mean	Variance
Uniform	$f(x; a, b) = \begin{cases} 1/(b-a) & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$	$\frac{e^{ibu} - e^{iau}}{(b-a)iu}$	$\frac{a+b}{2}$	$\frac{(b-a)^2}{12}$
Binomial	$f(r; N, p) = \frac{N!}{r!(N-r)!} p^r q^{N-r}$ $r = 0, 1, 2, \dots, N; \quad 0 \leq p \leq 1; \quad q = 1 - p$	$(q + pe^{iu})^N$	Np	Npq
Poisson	$f(n; \nu) = \frac{\nu^n e^{-\nu}}{n!}; \quad n = 0, 1, 2, \dots; \quad \nu > 0$	$\exp[\nu(e^{iu} - 1)]$	ν	ν

40. Statistics

Revised November 2021 by G. Cowan (RHUL).

This chapter gives an overview of statistical methods used in high-energy physics. In statistics, we are interested in using a given sample of data to make inferences about a probabilistic model, *e.g.*, to assess the model's validity or to determine the values of its parameters. There are two main approaches to statistical inference, which we may call frequentist and Bayesian.

40.2 Parameter estimation

An *estimator* $\hat{\theta}$ (written with a hat) is a function of the data used to estimate the value of the parameter θ .

40.2.1 Estimators for mean, variance, and median

Suppose we have a set of n independent measurements, x_1, \dots, x_n , each assumed to follow a p.d.f. with unknown mean μ and unknown variance σ^2 (the measurements do not necessarily have to follow a Gaussian distribution). Then

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^n x_i \quad (40.5)$$

$$\hat{\sigma}^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \hat{\mu})^2 \quad (40.6)$$

are unbiased estimators of μ and σ^2 . The variance of $\hat{\mu}$ is σ^2/n and the variance of $\hat{\sigma}^2$ is

$$V\left[\hat{\sigma}^2\right] = \frac{1}{n} \left(m_4 - \frac{n-3}{n-1} \sigma^4 \right), \quad (40.7)$$

where m_4 is the 4th central moment of x (see Eq. (39.8)). For Gaussian distributed x_i , this becomes $2\sigma^4/(n-1)$ for any $n \geq 2$, and for large n the standard deviation of $\hat{\sigma}$ is $\sigma/\sqrt{2n}$.

If the x_i have different, known variances σ_i^2 , then the weighted average

$$\hat{\mu} = \frac{1}{w} \sum_{i=1}^n w_i x_i, \quad (40.8)$$

where $w_i = 1/\sigma_i^2$ and $w = \sum_i w_i$, is an unbiased estimator for μ with a smaller variance than an unweighted average. The standard deviation of $\hat{\mu}$ is $1/\sqrt{w}$.

40.2.2 The method of maximum likelihood

Suppose we have a set of measured quantities \mathbf{x} and the likelihood $L(\boldsymbol{\theta}) = P(\mathbf{x}|\boldsymbol{\theta})$ for a set of parameters $\boldsymbol{\theta} = (\theta_1, \dots, \theta_N)$. The *maximum likelihood* (ML) estimators for $\boldsymbol{\theta}$ can be found by solving the *likelihood equations*,

$$\frac{\partial \ln L}{\partial \theta_i} = 0, \quad i = 1, \dots, N. \quad (40.9)$$

In the large sample limit, s times the standard deviations σ_i of the ML estimators can be obtained from the distances in θ_i to the planes tangent to the surface defined by

$$\ln L(\boldsymbol{\theta}) = \ln L_{\max} - s^2/2. \quad (40.13)$$

40.2.3 The method of least squares

For Gaussian distributed measurements y_i with mean $\mu(x_i; \theta)$ and known variance σ_i^2 , the log-likelihood function contains the sum of squares

$$\chi^2(\theta) = -2 \ln L(\theta) + \text{constant} = \sum_{i=1}^N \frac{(y_i - \mu(x_i; \theta))^2}{\sigma_i^2}. \quad (40.19)$$

If the y_i have a covariance matrix $V_{ij} = \text{cov}[y_i, y_j]$, then the estimators are determined by the minimum of

$$\chi^2(\theta) = (\mathbf{y} - \boldsymbol{\mu}(\theta))^T V^{-1} (\mathbf{y} - \boldsymbol{\mu}(\theta)), \quad (40.20)$$

40.3 Statistical tests

40.3.1 Hypothesis tests

A frequentist *test* of a hypothesis (often called the null hypothesis, H_0) is a rule that states for which data values \mathbf{x} the hypothesis is rejected. A critical region w is specified such that there is no more than a given probability α , called the *size* or *significance level* of the test, to find $\mathbf{x} \in w$. If the data are discrete, it may not be possible to find a critical region with exact probability content α , and thus we require $P(\mathbf{x} \in w | H_0) \leq \alpha$. If the data are observed in the critical region, H_0 is rejected.

The critical region is not unique, and generally defined relative to some alternative hypothesis (or set of alternatives) H_1 . To maximize the power of the test of H_0 with respect to the alternative H_1 , the *Neyman–Pearson lemma* states that the critical region w should be chosen such that for all data values \mathbf{x} inside w , the likelihood ratio

$$\lambda(\mathbf{x}) = \frac{f(\mathbf{x}|H_1)}{f(\mathbf{x}|H_0)} \quad (40.44)$$

is greater than or equal to a given constant c_α , and everywhere outside the critical region one has $\lambda(\mathbf{x}) < c_\alpha$, where the value of c_α is determined by the size of the test α . Here H_0 and H_1 must be simple hypotheses, *i.e.*, they should not contain undetermined parameters.

40.3.2 Tests of significance (goodness-of-fit)

Often one wants to quantify the level of agreement between the data and a hypothesis without explicit reference to alternative hypotheses. This can be done by defining a statistic t whose value reflects in some way the level of agreement between the data and the hypothesis. For example, if t is defined such that large values correspond to poor agreement with the hypothesis, then the *p-value* would be

$$p = \int_{t_{\text{obs}}}^{\infty} f(t|H_0) dt, \quad (40.45)$$

where t_{obs} is the value of the statistic obtained in the actual experiment.

40.3.2.3 Goodness-of-fit with the method of least squares

For Poisson measurements n_i with variances $\sigma_i^2 = \mu_i$, the χ^2 (40.19) becomes *Pearson's χ^2 statistic*,

$$\chi^2 = \sum_{i=1}^N \frac{(n_i - \mu_i)^2}{\mu_i}. \quad (40.54)$$

Assuming the goodness-of-fit statistic follows a χ^2 p.d.f., the p -value for the hypothesis is then

$$p = \int_{\chi^2}^{\infty} f(z; n_d) dz , \quad (40.55)$$

where $f(z; n_d)$ is the χ^2 p.d.f. and n_d is the appropriate number of degrees of freedom. Values are shown in Fig. 40.1. The p -values obtained for different values of χ^2/n_d are shown in Fig. 40.2.

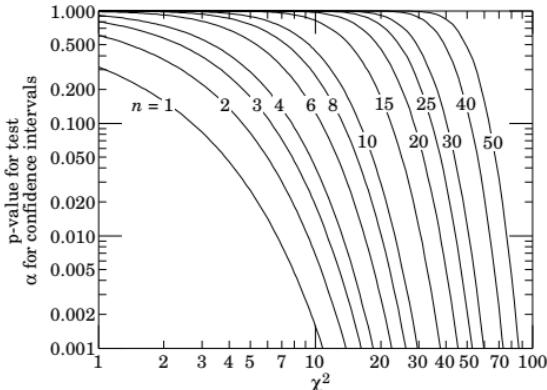

Figure 40.1: One minus the χ^2 cumulative distribution, $1 - F(\chi^2; n)$, for n degrees of freedom. This gives the p -value for the χ^2 goodness-of-fit test as well as one minus the coverage probability for confidence regions (see Sec. 40.4.2.2).

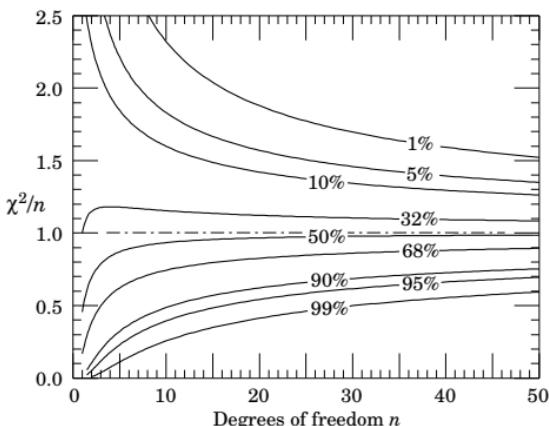

Figure 40.2: The ‘reduced’ χ^2 , equal to χ^2/n , for n degrees of freedom. The curves show as a function of n the χ^2/n that corresponds to a given p -value.

40.3.3 Bayes factors

In Bayesian statistics, one could reject a hypothesis H if its posterior probability $P(H|\mathbf{x})$ is sufficiently small. The full prior probability for two models (hypotheses) H_i and H_j can be written in the form

$$\pi(H_i, \boldsymbol{\theta}_i) = P(H_i)\pi(\boldsymbol{\theta}_i|H_i) . \quad (40.56)$$

The *Bayes factor* is defined as

$$B_{ij} = \frac{\int P(\mathbf{x}|\boldsymbol{\theta}_i, H_i) \pi(\boldsymbol{\theta}_i|H_i) d\boldsymbol{\theta}_i}{\int P(\mathbf{x}|\boldsymbol{\theta}_j, H_j) \pi(\boldsymbol{\theta}_j|H_j) d\boldsymbol{\theta}_j}. \quad (40.59)$$

This gives what the ratio of posterior probabilities for models i and j would be if the overall prior probabilities for the two models were equal.

40.4 Intervals and limits

40.4.1 Bayesian intervals

A Bayesian or credible interval) $[\theta_{lo}, \theta_{up}]$ can be determined which contains a given fraction $1 - \alpha$ of the posterior probability, *i.e.*,

$$1 - \alpha = \int_{\theta_{lo}}^{\theta_{up}} p(\theta|\mathbf{x}) d\theta. \quad (40.61)$$

40.4.2 Frequentist confidence intervals

40.4.2.1 The Neyman construction for confidence intervals

Given a p.d.f. $f(x; \theta)$, we can find using a pre-defined rule and probability $1 - \alpha$ for every value of θ , a set of values $x_1(\theta, \alpha)$ and $x_2(\theta, \alpha)$ such that

$$P(x_1 < x < x_2; \theta) = \int_{x_1}^{x_2} f(x; \theta) dx \geq 1 - \alpha. \quad (40.68)$$

40.4.2.2 Gaussian distributed measurements

When the data consists of a single random variable x that follows a Gaussian distribution with known σ , the probability that the measured value x will fall within $\pm\delta$ of the true value μ is

$$\begin{aligned} 1 - \alpha &= \frac{1}{\sqrt{2\pi}\sigma} \int_{\mu-\delta}^{\mu+\delta} e^{-(x-\mu)^2/2\sigma^2} dx \\ &= \text{erf}\left(\frac{\delta}{\sqrt{2}\sigma}\right) = 2\Phi\left(\frac{\delta}{\sigma}\right) - 1, \end{aligned} \quad (40.71)$$

Fig. 40.4 shows a $\delta = 1.64\sigma$ confidence interval unshaded. Values of α for other frequently used choices of δ are given in Table 40.1.

Table 40.1: Area of the tails α outside $\pm\delta$ from the mean of a Gaussian distribution.

α	δ	α	δ
0.3173	1σ	0.2	1.28σ
4.55×10^{-2}	2σ	0.1	1.64σ
2.7×10^{-3}	3σ	0.05	1.96σ
6.3×10^{-5}	4σ	0.01	2.58σ
5.7×10^{-7}	5σ	0.001	3.29σ
2.0×10^{-9}	6σ	10^{-4}	3.89σ

We can set a one-sided (upper or lower) limit by excluding above $x + \delta$ (or below $x - \delta$). The values of α for such limits are half the values in Table 40.1. Values of $\Delta\chi^2$ or $2\Delta \ln L$ are given in Table 40.2 for several values of the coverage probability $1 - \alpha$ and number of fitted parameters m .

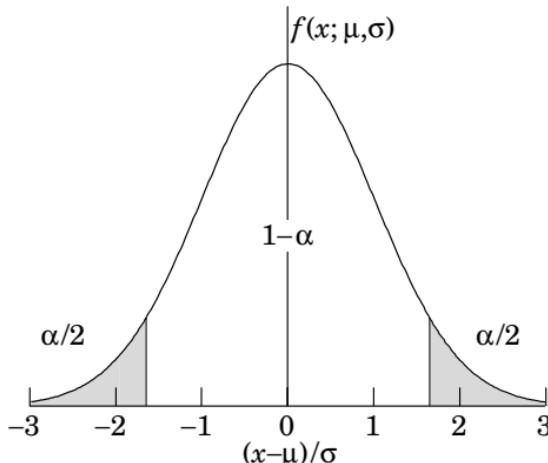

Figure 40.4: Illustration of a symmetric 90% confidence interval (unshaded) for a Gaussian-distributed measurement of a single quantity. Integrated probabilities, defined by $\alpha = 0.1$, are as shown.

Table 40.2: Values of $\Delta\chi^2$ or $2\Delta \ln L$ corresponding to a coverage probability $1-\alpha$ in the large data sample limit, for joint estimation of m parameters.

$(1-\alpha) (\%)$	$m=1$	$m=2$	$m=3$
68.27	1.00	2.30	3.53
90.	2.71	4.61	6.25
95.	3.84	5.99	7.82
95.45	4.00	6.18	8.03
99.	6.63	9.21	11.34
99.73	9.00	11.83	14.16

40.4.2.3 Poisson or binomial data

For Poisson distributed n , the upper and lower limits on the mean value μ from the Neyman procedure are

$$\mu_{\text{lo}} = \frac{1}{2} F_{\chi^2}^{-1}(\alpha_{\text{lo}}; 2n), \quad (40.77\text{a})$$

$$\mu_{\text{up}} = \frac{1}{2} F_{\chi^2}^{-1}(1 - \alpha_{\text{up}}; 2(n+1)), \quad (40.77\text{b})$$

For the case of binomially distributed n successes out of N trials with probability of success p , the upper and lower limits on p are found to be

$$p_{\text{lo}} = \frac{n F_F^{-1}[\alpha_{\text{lo}}; 2n, 2(N-n+1)]}{N-n+1 + n F_F^{-1}[\alpha_{\text{lo}}; 2n, 2(N-n+1)]}, \quad (40.78\text{a})$$

$$p_{\text{up}} = \frac{(n+1) F_F^{-1}[1 - \alpha_{\text{up}}; 2(n+1), 2(N-n)]}{(N-n) + (n+1) F_F^{-1}[1 - \alpha_{\text{up}}; 2(n+1), 2(N-n)]}. \quad (40.78\text{b})$$

Here F_F^{-1} is the quantile of the F distribution (also called the Fisher-Snedecor distribution; see Ref. [4]).

Several problems with such intervals are overcome by using the unified approach of Feldman and Cousins [33]. Properties of these intervals are described further in the *Review*. Table 40.4 gives the unified confidence

Table 40.3: Lower and upper (one-sided) limits for the mean μ of a Poisson variable given n observed events in the absence of background, for confidence levels of 90% and 95%.

n	$1 - \alpha = 90\%$		$1 - \alpha = 95\%$

45. Monte Carlo Particle Numbering Scheme

Revised August 2021 by F. Krauss (Durham U.), S. Navas (Granada U.), P. Richardson (Durham U.) and T. Sjöstrand (Lund U.).

The Monte Carlo particle numbering scheme presented here is intended to facilitate interfacing between matrix-element generators, event generators, detector simulators, and analysis packages used in particle physics, and is widely accepted as the “industry standard”. The general form is a 7-digit number:

$$\pm n \ n_r \ n_L \ n_{q_1} \ n_{q_2} \ n_{q_3} \ n_J .$$

Tetra- and penta-quark state are signified by a 9-digit code, and nuclear codes are 10-digit numbers. This encodes information about the particle’s spin, flavor content, and internal quantum numbers: See the full review for details. An *abbreviated* list of common or well-measured particles follows below.

49. Kinematics

Revised August 2021 by D.J. Miller (Glasgow U.) and D.R. Tovey (Sheffield U.).

Throughout this section units are used in which $\hbar = c = 1$. The following conversions are useful: $\hbar c = 197.3 \text{ MeV fm}$, $(\hbar c)^2 = 0.3894 (\text{GeV})^2 \text{ mb}$.

49.1 Lorentz transformations

The energy E and 3-momentum \mathbf{p} of a particle of mass m form a 4-vector $\mathbf{p} = (E, \mathbf{p})$ whose square $p^2 \equiv E^2 - |\mathbf{p}|^2 = m^2$. The velocity of the particle is $\beta = \mathbf{p}/E$. The energy and momentum (E^*, \mathbf{p}^*) viewed from a frame moving with velocity β_f are given by

$$\begin{pmatrix} E^* \\ p_{\parallel}^* \end{pmatrix} = \begin{pmatrix} \gamma_f & -\gamma_f \beta_f \\ -\gamma_f \beta_f & \gamma_f \end{pmatrix} \begin{pmatrix} E \\ p_{\parallel} \end{pmatrix}, \quad p_T^* = p_T, \quad (49.1)$$

where $\gamma_f = (1 - \beta_f^2)^{-1/2}$ and p_T (p_{\parallel}) are the components of \mathbf{p} perpendicular (parallel) to β_f . Other 4-vectors, such as the space-time coordinates of events, of course transform in the same way. The scalar product of two 4-momenta $p_1 \cdot p_2 = E_1 E_2 - \mathbf{p}_1 \cdot \mathbf{p}_2$ is invariant (frame independent).

49.2 Center-of-mass energy and momentum

In the collision of two particles of masses m_1 and m_2 the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$\begin{aligned} E_{\text{cm}} &= [(E_1 + E_2)^2 - (\mathbf{p}_1 + \mathbf{p}_2)^2]^{1/2}, \\ &= [m_1^2 + m_2^2 + 2E_1 E_2 (1 - \beta_1 \beta_2 \cos \theta)]^{1/2}, \end{aligned} \quad (49.2)$$

where θ is the angle between the particles. In the frame where one particle (of mass m_2) is at rest (lab frame),

$$E_{\text{cm}} = (m_1^2 + m_2^2 + 2E_1 \text{lab} m_2)^{1/2}. \quad (49.3)$$

The velocity of the center-of-mass in the lab frame is

$$\beta_{\text{cm}} = \mathbf{p}_{\text{lab}} / (E_1 \text{lab} + m_2), \quad (49.4)$$

where $\mathbf{p}_{\text{lab}} \equiv \mathbf{p}_1 \text{lab}$ and

$$\gamma_{\text{cm}} = (E_1 \text{lab} + m_2) / E_{\text{cm}}. \quad (49.5)$$

The c.m. momenta of particles 1 and 2 are of magnitude

$$p_{\text{cm}} = p_{\text{lab}} \frac{m_2}{E_{\text{cm}}}. \quad (49.6)$$

For example, if a $0.80 \text{ GeV}/c$ kaon beam is incident on a proton target, the center of mass energy is 1.699 GeV and the center of mass momentum of either particle is $0.442 \text{ GeV}/c$. It is also useful to note that

$$E_{\text{cm}} dE_{\text{cm}} = m_2 dE_1 \text{lab} = m_2 \beta_1 \text{lab} dp_{\text{lab}}. \quad (49.7)$$

49.3 Lorentz-invariant amplitudes

The matrix elements for a scattering or decay process are written in terms of an invariant amplitude $-i\mathcal{M}$. As an example, the S -matrix for $2 \rightarrow 2$ scattering is related to \mathcal{M} by

$$\langle p'_1 p'_2 | S - 1 | p_1 p_2 \rangle = i(2\pi)^4 \delta^4(p_1 + p_2 - p'_1 - p'_2) \mathcal{M}(p_1, p_2; p'_1, p'_2). \quad (49.8)$$

The state normalization is such that

$$\langle p' | p \rangle = (2\pi)^3 2E_p \delta^3(\mathbf{p}' - \mathbf{p}), \quad (49.9)$$

with $E_p = \sqrt{\mathbf{p}^2 + m^2}$.

49.4 Particle decays

The partial decay rate of a particle of mass M into n bodies in its rest frame is given in terms of the Lorentz-invariant matrix element \mathcal{M} by

$$d\Gamma = \frac{(2\pi)^4}{2M} |\mathcal{M}|^2 d\Phi_n(P; p_1, \dots, p_n), \quad (49.11)$$

where $d\Phi_n$ is an element of n -body phase space given by

$$d\Phi_n(P; p_1, \dots, p_n) = \delta^4(P - \sum_{i=1}^n p_i) \prod_{i=1}^n \frac{d^3 p_i}{(2\pi)^3 2E_i}. \quad (49.12)$$

This phase space is reduced by combinatoric factors whenever there are identical particles in the final state. The phase space can be generated recursively, viz.

$$\begin{aligned} d\Phi_n(P; p_1, \dots, p_n) &= d\Phi_j(q; p_1, \dots, p_j) \\ &\times d\Phi_{n-j+1}(P; q, p_{j+1}, \dots, p_n)(2\pi)^3 dq^2, \end{aligned} \quad (49.13)$$

where $q^2 = (\sum_{i=1}^j E_i)^2 - |\sum_{i=1}^j \mathbf{p}_i|^2$. This form is particularly useful in the case where a particle decays into another particle that subsequently decays.

49.4.1 Survival probability

If a particle of mass M has mean proper lifetime τ ($= 1/\Gamma$) and has momentum (E, \mathbf{p}) , then the probability that it lives for a time t_0 or greater before decaying is given by

$$P(t_0) = e^{-t_0 \Gamma/\gamma} = e^{-Mt_0 \Gamma/E}, \quad (49.14)$$

and the probability that it travels a distance x_0 or greater is

$$P(x_0) = e^{-Mx_0 \Gamma/|\mathbf{p}|}. \quad (49.15)$$

49.4.2 Two-body decays

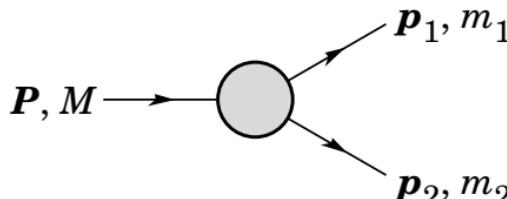

Figure 49.1: Definitions of variables for two-body decays.

In the rest frame of a particle of mass M , decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M}, \quad (49.16)$$

$$|\mathbf{p}_1| = |\mathbf{p}_2| = \frac{1}{2M} \sqrt{\lambda(M^2, m_1^2, m_2^2)}, \quad (49.17)$$

and

$$d\Gamma = \frac{1}{32\pi^2} |\mathcal{M}|^2 \frac{|\mathbf{p}_1|}{M^2} d\Omega, \quad (49.18)$$

where $\lambda(\alpha, \beta, \gamma) = \alpha^2 + \beta^2 + \gamma^2 - 2\alpha\beta - 2\alpha\gamma - 2\beta\gamma$ is the Källén function and $d\Omega = d\phi_1 d(\cos \theta_1)$ is the solid angle of particle 1. The invariant mass M can be determined from the energies and momenta using Eq. (49.2) with $M = E_{\text{cm}}$.

49.4.3 Three-body decays

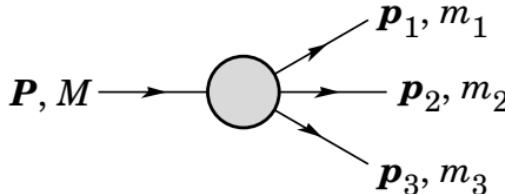

Figure 49.2: Definitions of variables for three-body decays.

Defining $p_{ij} = p_i + p_j$ and $m_{ij}^2 = p_{ij}^2$, then $m_{12}^2 + m_{23}^2 + m_{13}^2 = M^2 + m_1^2 + m_2^2 + m_3^2$ and $m_{12}^2 = (P - p_3)^2 = M^2 + m_3^2 - 2ME_3$, where E_3 is the energy of particle 3 in the rest frame of M . In that frame, the momenta of the three decay particles lie in a plane. The relative orientation of these three momenta is fixed if their energies are known. The momenta can therefore be specified in space by giving three Euler angles (α, β, γ) that specify the orientation of the final system relative to the initial particle. The direction of any one of the particles relative to the frame in which the initial particle is described can be specified in space by two angles (α, β) while a third angle, γ , can be set as the azimuthal angle of a second particle around the first [1]. Then

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M} |\mathcal{M}|^2 dE_1 dE_3 d\alpha d(\cos \beta) d\gamma . \quad (49.19)$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M^2} |\mathcal{M}|^2 |\mathbf{p}_1^*| |\mathbf{p}_3| dm_{12} d\Omega_1^* d\Omega_3 , \quad (49.20)$$

where $(|\mathbf{p}_1^*|, \Omega_1^*)$ is the momentum of particle 1 in the rest frame of 1 and 2, and Ω_3 is the angle of particle 3 in the rest frame of the decaying particle. $|\mathbf{p}_1^*|$ and $|\mathbf{p}_3|$ are given by

$$|\mathbf{p}_1^*| = \frac{1}{2m_{12}} \sqrt{\lambda(m_{12}^2, m_1^2, m_2^2)} , \quad (49.21a)$$

and

$$|\mathbf{p}_3| = \frac{1}{2M} \sqrt{\lambda(M^2, m_{12}^2, m_3^2)} . \quad (49.21b)$$

[Compare with Eq. (49.17).]

If the decaying particle is a scalar or we average over its spin states, then integration over the angles in Eq. (49.19) gives

$$\begin{aligned} d\Gamma &= \frac{1}{(2\pi)^3} \frac{1}{8M} \overline{|\mathcal{M}|^2} dE_1 dE_3 \\ &= \frac{1}{(2\pi)^3} \frac{1}{32M^3} \overline{|\mathcal{M}|^2} dm_{12}^2 dm_{23}^2 . \end{aligned} \quad (49.22)$$

This is the standard form for the Dalitz plot.

49.4.3.1 Dalitz plot

For a given value of m_{12}^2 , the range of m_{23}^2 is determined by its values when \mathbf{p}_2 is parallel or antiparallel to \mathbf{p}_3 :

$$(m_{23}^2)_{\max} = (E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} - \sqrt{E_3^{*2} - m_3^2} \right)^2 , \quad (49.23a)$$

$$(m_{23}^2)_{\min} = (E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} + \sqrt{E_3^{*2} - m_3^2} \right)^2 . \quad (49.23b)$$

Here $E_2^* = (m_{12}^2 - m_1^2 + m_2^2)/2m_{12}$ and $E_3^* = (M^2 - m_{12}^2 - m_3^2)/2m_{12}$ are the energies of particles 2 and 3 in the m_{12} rest frame. The scatter plot in m_{12}^2 and m_{23}^2 is called a Dalitz plot. If $|\mathcal{M}|^2$ is constant, the allowed region of the plot will be uniformly populated with events [see Eq. (49.22)]. A nonuniformity in the plot gives immediate information on $|\mathcal{M}|^2$. For example, in the case of $D \rightarrow K\pi\pi$, bands appear when $m_{(K\pi)} = m_{K^*(892)}$, reflecting the appearance of the decay chain $D \rightarrow K^*(892)\pi \rightarrow K\pi\pi$.

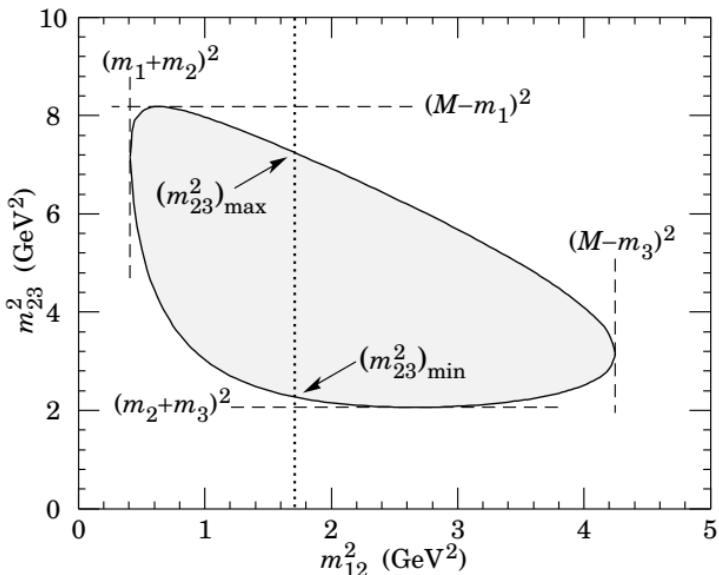

Figure 49.3: Dalitz plot for a three-body final state. In this example, the state is $\pi^+\bar{K}^0 p$ at 3 GeV. Four-momentum conservation restricts events to the shaded region.

49.4.4 Kinematic limits

49.4.4.1 Three-body decays

In a three-body decay (Fig. 49.2) the maximum of $|\mathbf{p}_3|$, [given by Eq. (49.21)], is achieved when $m_{12} = m_1 + m_2$, i.e., particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition, $m_3 > m_1, m_2$, then $|\mathbf{p}_3|_{\max} > |\mathbf{p}_1|_{\max}, |\mathbf{p}_2|_{\max}$. The distribution of m_{12} values possesses an end-point or maximum value at $m_{12} = M - m_3$. This can be used to constrain the mass difference of a parent particle and one invisible decay product.

49.4.5 Multibody decays

The above results may be generalized to final states containing any number of particles by combining some of the particles into “effective particles” and treating the final states as 2 or 3 “effective particle” states. Thus, if $p_{ijk\dots} = p_i + p_j + p_k + \dots$, then

$$m_{ijk\dots} = \sqrt{p_{ijk\dots}^2} , \quad (49.26)$$

and $m_{ijk\dots}$ may be used in place of e.g., m_{12} in the relations in Sec. 49.4.3 or Sec. 49.4.4 above.

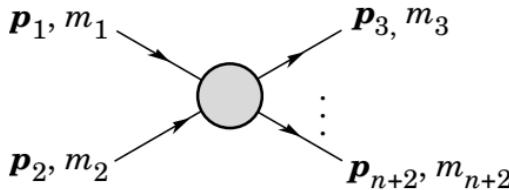

Figure 49.5: Definitions of variables for production of an n -body final state.

49.5 Cross sections

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4 |\mathcal{M}|^2}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}} \times d\Phi_n(p_1 + p_2; p_3, \dots, p_{n+2}) . \quad (49.27)$$

[See Eq. (49.12).] In the rest frame of m_2 (lab),

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = m_2 p_{1\text{lab}} ; \quad (49.28\text{a})$$

while in the center-of-mass frame

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = p_{1\text{cm}} \sqrt{s} . \quad (49.28\text{b})$$

49.5.1 Two-body reactions

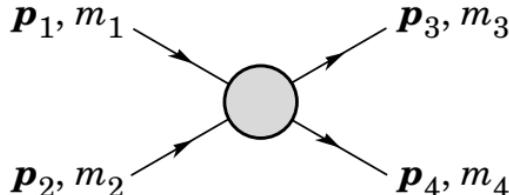

Figure 49.6: Definitions of variables for a two-body final state.

Two particles of momenta p_1 and p_2 and masses m_1 and m_2 scatter to particles of momenta p_3 and p_4 and masses m_3 and m_4 ; the Lorentz-invariant Mandelstam variables are defined by

$$\begin{aligned} s &= (p_1 + p_2)^2 = (p_3 + p_4)^2 \\ &= m_1^2 + 2E_1 E_2 - 2\mathbf{p}_1 \cdot \mathbf{p}_2 + m_2^2 , \end{aligned} \quad (49.29)$$

$$\begin{aligned} t &= (p_1 - p_3)^2 = (p_2 - p_4)^2 \\ &= m_1^2 - 2E_1 E_3 + 2\mathbf{p}_1 \cdot \mathbf{p}_3 + m_3^2 , \end{aligned} \quad (49.30)$$

$$\begin{aligned} u &= (p_1 - p_4)^2 = (p_2 - p_3)^2 \\ &= m_1^2 - 2E_1 E_4 + 2\mathbf{p}_1 \cdot \mathbf{p}_4 + m_4^2 , \end{aligned} \quad (49.31)$$

and they satisfy

$$s + t + u = m_1^2 + m_2^2 + m_3^2 + m_4^2 . \quad (49.32)$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s} \frac{1}{|\mathbf{p}_{1\text{cm}}|^2} |\mathcal{M}|^2 . \quad (49.33)$$

In the center-of-mass frame

$$\begin{aligned} t &= (E_{1\text{cm}} - E_{3\text{cm}})^2 - (p_{1\text{cm}} - p_{3\text{cm}})^2 = t_0 - 4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2) \\ &= t_0 - 4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2), \end{aligned} \quad (49.34)$$

where θ_{cm} is the angle between particle 1 and 3. The limiting values t_0 ($\theta_{\text{cm}} = 0$) and t_1 ($\theta_{\text{cm}} = \pi$) for $2 \rightarrow 2$ scattering are

$$t_0(t_1) = \left[\frac{m_1^2 - m_3^2 - m_2^2 + m_4^2}{2\sqrt{s}} \right]^2 - (p_{1\text{cm}} \mp p_{3\text{cm}})^2. \quad (49.35)$$

In the literature the notation t_{\min} (t_{\max}) for t_0 (t_1) is sometimes used, which should be discouraged since $t_0 > t_1$. The center-of-mass energies and momenta of the incoming particles are

$$E_{1\text{cm}} = \frac{s + m_1^2 - m_2^2}{2\sqrt{s}}, \quad E_{2\text{cm}} = \frac{s + m_2^2 - m_1^2}{2\sqrt{s}}, \quad (49.36)$$

For $E_{3\text{cm}}$ and $E_{4\text{cm}}$, change m_1 to m_3 and m_2 to m_4 . Then

$$p_{i\text{cm}} = \sqrt{E_{i\text{cm}}^2 - m_i^2} \text{ and } p_{1\text{cm}} = \frac{p_{1\text{lab}} m_2}{\sqrt{s}}. \quad (49.37)$$

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (49.2)–(49.4).]

49.5.2 Inclusive reactions

Choose some direction (usually the beam direction) for the z -axis; then the energy and momentum of a particle can be written as

$$E = m_T \cosh y, \quad p_x, \quad p_y, \quad p_z = m_T \sinh y, \quad (49.38)$$

where m_T , conventionally called the ‘transverse mass’, is given by

$$m_T^2 = m^2 + p_x^2 + p_y^2. \quad (49.39)$$

and the rapidity y is defined by

$$\begin{aligned} y &= \frac{1}{2} \ln \left(\frac{E + p_z}{E - p_z} \right) \\ &= \ln \left(\frac{E + p_z}{m_T} \right) = \tanh^{-1} \left(\frac{p_z}{E} \right). \end{aligned} \quad (49.40)$$

Note that the definition of the transverse mass in Eq. (49.39) differs from that used by experimentalists at hadron colliders (see Sec. 49.6.1 below). Under a boost in the z -direction to a frame with velocity β , $y \rightarrow y - \tanh^{-1} \beta$. Hence the shape of the rapidity distribution dN/dy is invariant, as are differences in rapidity. The invariant cross section may also be rewritten

$$E \frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi dy p_T dp_T} \Rightarrow \frac{d^2\sigma}{\pi dy d(p_T^2)}. \quad (49.41)$$

The second form is obtained using the identity $dy/dp_z = 1/E$, and the third form represents the average over ϕ .

Feynman’s x variable is given by

$$x = \frac{p_z}{p_{z\text{ max}}} \approx \frac{E + p_z}{(E + p_z)_{\text{max}}} \quad (p_T \ll |p_z|). \quad (49.42)$$

In the c.m. frame,

$$x \approx \frac{2p_{z\text{cm}}}{\sqrt{s}} = \frac{2m_T \sinh y_{\text{cm}}}{\sqrt{s}} \quad (49.43)$$

and

$$= (y_{\text{cm}})_{\text{max}} = \ln(\sqrt{s}/m) . \quad (49.44)$$

The invariant mass M of the two-particle system described in Sec. 49.4.2 can be written in terms of these variables as

$$M^2 = m_1^2 + m_2^2 + 2[E_T(1)E_T(2)\cosh\Delta y - \mathbf{p}_T(1) \cdot \mathbf{p}_T(2)] , \quad (49.45)$$

where

$$E_T(i) = \sqrt{|\mathbf{p}_T(i)|^2 + m_i^2} , \quad (49.46)$$

and $\mathbf{p}_T(i)$ denotes the transverse momentum vector of particle i .

For $p \gg m$, the rapidity [Eq. (49.40)] may be expanded to obtain

$$\begin{aligned} y &= \frac{1}{2} \ln \frac{\cos^2(\theta/2) + m^2/4p^2 + \dots}{\sin^2(\theta/2) + m^2/4p^2 + \dots} \\ &\approx -\ln \tan(\theta/2) \equiv \eta \end{aligned} \quad (49.47)$$

where $\cos\theta = p_z/p$. The pseudorapidity η defined by the second line is approximately equal to the rapidity y for $p \gg m$ and $\theta \gg 1/\gamma$, and in any case can be measured when the mass and momentum of the particle are unknown. From the definition one can obtain the identities

$$\sinh\eta = \cot\theta , \quad \cosh\eta = 1/\sin\theta , \quad \tanh\eta = \cos\theta . \quad (49.48)$$

49.6 Transverse variables

At hadron colliders, a significant and unknown proportion of the energy of the incoming hadrons in each event escapes down the beam-pipe. Consequently if invisible particles are created in the final state, their net momentum can only be constrained in the plane transverse to the beam direction. Defining the z -axis as the beam direction, this net momentum is equal to the missing transverse energy vector

$$\mathbf{E}_T^{\text{miss}} = - \sum_i \mathbf{p}_T(i) , \quad (49.49)$$

where the sum runs over the transverse momenta of all visible final state particles.

49.6.1 Single production with semi-invisible final state

Consider a single heavy particle of mass M produced in association with visible particles which decays as in Fig. 49.1 to two particles, of which one (labeled particle 1) is invisible. The mass of the parent particle can be constrained with the quantity M_T defined by

$$\begin{aligned} M_T^2 &\equiv [E_T(1) + E_T(2)]^2 - [\mathbf{p}_T(1) + \mathbf{p}_T(2)]^2 \\ &= m_1^2 + m_2^2 + 2[E_T(1)E_T(2) - \mathbf{p}_T(1) \cdot \mathbf{p}_T(2)] , \end{aligned} \quad (49.50)$$

where

$$\mathbf{p}_T(1) = \mathbf{E}_T^{\text{miss}} . \quad (49.51)$$

This quantity is called the ‘transverse mass’ by hadron collider experimentalists but it should be noted that it is quite different from that used in the description of inclusive reactions [Eq. (49.39)]. The distribution of event M_T values possesses an end-point at $M_T^{\text{max}} = M$. If $m_1 = m_2 = 0$ then

$$M_T^2 = 2|\mathbf{p}_T(1)||\mathbf{p}_T(2)|(1 - \cos\phi_{12}) , \quad (49.52)$$

where ϕ_{ij} is defined as the angle between particles i and j in the transverse plane.

49.6.2 Pair production with semi-invisible final states

Consider two identical heavy particles of mass M produced such that their combined center-of-mass is at rest in the transverse plane (Fig. 49.7). Each particle decays to a final state consisting of an invisible particle of fixed mass m_1 together with an additional visible particle. M and m_1 can be constrained with the variables M_{T2} and M_{CT} which are defined in Refs. [4] and [5].¹

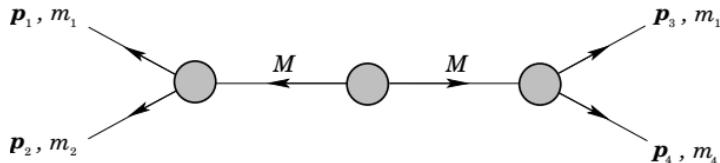

Figure 49.7: Definitions of variables for pair production of semi-invisible final states. Particles 1 and 3 are invisible while particles 2 and 4 are visible.

51. Cross-Section Formulae for Specific Processes

Revised August 2019 by H. Baer (Oklahoma U.) and R.N. Cahn (LBNL).

PART I: Standard Model Processes

Setting aside lepto-production (for which, see Sec. 16 of this *Review*), the cross sections of primary interest are those with light incident particles, e^+e^- , $\gamma\gamma$, $q\bar{q}$, gg , etc., where g and q represent gluons and light quarks. The produced particles include both light particles and heavy ones - t , W , Z , and the Higgs boson H . We provide the production cross sections calculated within the Standard Model for several such processes.

51.1 Resonance Formation

Resonant cross sections are generally described by the Breit-Wigner formula (Sec. 18 of this *Review*).

$$\sigma(E) = \frac{2J+1}{(2S_1+1)(2S_2+1)} \frac{4\pi}{k^2} \left[\frac{\Gamma^2/4}{(E-E_0)^2 + \Gamma^2/4} \right] B_{in} B_{out}, \quad (51.1)$$

where E is the c.m. energy, J is the spin of the resonance, and the number of polarization states of the two incident particles are $2S_1+1$ and $2S_2+1$. The c.m. momentum in the initial state is k , E_0 is the c.m. energy at the resonance, and Γ is the full width at half maximum height of the resonance. The branching fraction for the resonance into the initial-state channel is B_{in} and into the final-state channel is B_{out} . For a narrow resonance, the factor in square brackets may be replaced by $\pi\Gamma\delta(E-E_0)/2$.

51.2 Production of light particles

The production of point-like, spin-1/2 fermions in e^+e^- annihilation through a virtual photon, $e^+e^- \rightarrow \gamma^* \rightarrow f\bar{f}$, at c.m. energy squared s is

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta [1 + \cos^2 \theta + (1 - \beta^2) \sin^2 \theta] Q_f^2, \quad (51.2)$$

where β is v/c for the produced fermions in the c.m., θ is the c.m. scattering angle, and Q_f is the charge of the fermion. The factor N_c is 1 for charged leptons and 3 for quarks. In the ultrarelativistic limit, $\beta \rightarrow 1$,

$$\sigma = N_c Q_f^2 \frac{4\pi\alpha^2}{3s} = N_c Q_f^2 \frac{86.8 \text{ nb}}{s(\text{GeV}^2)}. \quad (51.3)$$

The cross section for the annihilation of a $q\bar{q}$ pair into a distinct pair $q'\bar{q}'$ through a gluon is completely analogous up to color factors, with the replacement $\alpha \rightarrow \alpha_s$. Treating all quarks as massless, averaging over the colors of the initial quarks and defining $t = -s \sin^2(\theta/2)$, $u = -s \cos^2(\theta/2)$, one finds

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q'\bar{q}') = \frac{\alpha_s^2}{9s} \frac{t^2 + u^2}{s^2}. \quad (51.4)$$

Crossing symmetry gives

$$\frac{d\sigma}{d\Omega}(qq' \rightarrow qq') = \frac{\alpha_s^2}{9s} \frac{s^2 + u^2}{t^2}. \quad (51.5)$$

If the quarks q and q' are identical, we have

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q\bar{q}) = \frac{\alpha_s^2}{9s} \left[\frac{t^2 + u^2}{s^2} + \frac{s^2 + u^2}{t^2} - \frac{2u^2}{3st} \right], \quad (51.6)$$

and by crossing

$$\frac{d\sigma}{d\Omega}(qq \rightarrow qq) = \frac{\alpha_s^2}{9s} \left[\frac{t^2 + s^2}{u^2} + \frac{s^2 + u^2}{t^2} - \frac{2s^2}{3ut} \right]. \quad (51.7)$$

Annihilation of $e^+ e^-$ into $\gamma\gamma$ has the cross section

$$\frac{d\sigma}{d\Omega}(e^+ e^- \rightarrow \gamma\gamma) = \frac{\alpha^2}{2s} \frac{u^2 + t^2}{tu} . \quad (51.8)$$

The related QCD process also has a triple-gluon coupling. The cross section is

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow gg) = \frac{8\alpha_s^2}{27s} (t^2 + u^2) \left(\frac{1}{tu} - \frac{9}{4s^2} \right) . \quad (51.9)$$

The crossed reactions are

$$\frac{d\sigma}{d\Omega}(qg \rightarrow qg) = \frac{\alpha_s^2}{9s} (s^2 + u^2) \left(-\frac{1}{su} + \frac{9}{4t^2} \right) , \quad (51.10)$$

$$\frac{d\sigma}{d\Omega}(gg \rightarrow q\bar{q}) = \frac{\alpha_s^2}{24s} (t^2 + u^2) \left(\frac{1}{tu} - \frac{9}{4s^2} \right) , \quad (51.11)$$

$$\frac{d\sigma}{d\Omega}(gg \rightarrow gg) = \frac{9\alpha_s^2}{8s} \left(3 - \frac{ut}{s^2} - \frac{su}{t^2} - \frac{st}{u^2} \right) . \quad (51.12)$$

Lepton-quark scattering is analogous (neglecting Z exchange)

$$\frac{d\sigma}{d\Omega}(eq \rightarrow eq) = \frac{\alpha^2}{2s} e_q^2 \frac{s^2 + u^2}{t^2} , \quad (51.13)$$

e_q is the quark charge. For ν -scattering with the four-Fermi interaction

$$\frac{d\sigma}{d\Omega}(\nu d \rightarrow \ell^- u) = \frac{G_F^2 s}{4\pi^2} , \quad (51.14)$$

where the Cabibbo angle suppression is ignored. Similarly

$$\frac{d\sigma}{d\Omega}(\nu \bar{u} \rightarrow \ell^- \bar{d}) = \frac{G_F^2 s}{4\pi^2} \frac{(1 + \cos\theta)^2}{4} . \quad (51.15)$$

For deep inelastic scattering (presented in more detail in Section 19) we consider quarks of type i carrying a fraction $x = Q^2/(2M\nu)$ of the nucleon's energy, where $\nu = E - E'$ is the energy lost by the lepton in the nucleon rest frame. With $y = \nu/E$ we have the correspondences

$$1 + \cos\theta \rightarrow 2(1 - y) , \quad d\Omega_{cm} \rightarrow 4\pi f_i(x) dx dy , \quad (51.16)$$

where the latter incorporates the quark distribution, $f_i(x)$. We find

$$\begin{aligned} \frac{d\sigma}{dx dy}(eN \rightarrow eX) &= \frac{4\pi\alpha^2 xs}{Q^4} \frac{1}{2} [1 + (1 - y)^2] \\ &\times \left[\frac{4}{9}(u(x) + \bar{u}(x) + \dots) + \frac{1}{9}(d(x) + \bar{d}(x) + \dots) \right] \end{aligned} \quad (51.17)$$

where now $s = 2ME$ is the cm energy squared for the electron-nucleon collision and we have suppressed contributions from higher mass quarks.

Similarly,

$$\frac{d\sigma}{dx dy}(\nu N \rightarrow \ell^- X) = \frac{G_F^2 xs}{\pi} [(d(x) + \dots) + (1 - y)^2 (\bar{u}(x) + \dots)] , \quad (51.18)$$

$$\frac{d\sigma}{dx dy}(\bar{\nu} N \rightarrow \ell^+ X) = \frac{G_F^2 xs}{\pi} [(\bar{d}(x) + \dots) + (1 - y)^2 (u(x) + \dots)] . \quad (51.19)$$

Quasi-elastic neutrino scattering ($\nu_\mu n \rightarrow \mu^- p$, $\bar{\nu}_\mu p \rightarrow \mu^+ n$) is directly related to the crossed reaction, neutron decay.

51.3 Hadroproduction of heavy quarks

For hadroproduction of heavy quarks $Q = c, b, t$, it is important to include mass effects in the formulae. For $q\bar{q} \rightarrow Q\bar{Q}$, one has

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow Q\bar{Q}) = \frac{\alpha_s^2}{9s^3} \sqrt{1 - \frac{4m_Q^2}{s}} \left[(m_Q^2 - t)^2 + (m_Q^2 - u)^2 + 2m_Q^2 s \right] , \quad (51.20)$$

while for $gg \rightarrow Q\bar{Q}$ one has

$$\begin{aligned}
\frac{d\sigma}{d\Omega}(gg \rightarrow Q\bar{Q}) &= \frac{\alpha_s^2}{32s} \sqrt{1 - \frac{4m_Q^2}{s}} \left[\frac{6}{s^2} (m_Q^2 - t)(m_Q^2 - u) \right. \\
&- \frac{m_Q^2(s - 4m_Q^2)}{3(m_Q^2 - t)(m_Q^2 - u)} + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + t)}{(m_Q^2 - t)^2} \\
&\left. + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + u)}{(m_Q^2 - u)^2} \right] \\
&- 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(u - t)}{s(m_Q^2 - t)} - 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(t - u)}{s(m_Q^2 - u)} \Bigg]. \tag{51.21}
\end{aligned}$$

51.4 Production of Weak Gauge Bosons

51.4.1 W and Z resonant production

Resonant production of a single W or Z is governed by the partial widths

$$\Gamma(W \rightarrow \ell_i \bar{\nu}_i) = \frac{\sqrt{2}G_F m_W^3}{12\pi} \tag{51.22}$$

$$\Gamma(W \rightarrow q_i \bar{q}_j) = 3 \frac{\sqrt{2}G_F |V_{ij}|^2 m_W^3}{12\pi} \tag{51.23}$$

$$\begin{aligned}
\Gamma(Z \rightarrow f\bar{f}) &= N_c \frac{\sqrt{2}G_F m_Z^3}{6\pi} \\
&\times [(T_3 - Q_f \sin^2 \theta_W)^2 + (Q_f \sin^2 \theta_W)^2] \tag{51.24}
\end{aligned}$$

The weak mixing angle is θ_W . The CKM matrix elements are V_{ij} . N_c is 3 for $q\bar{q}$ and 1 for leptonic final states. These widths along with associated branching fractions may be applied to the resonance production formula of Sec. 51.1 to gain the total W or Z production cross section.

51.4.2 Production of pairs of weak gauge bosons

The cross section for $f\bar{f} \rightarrow W^+W^-$ is given in term of the couplings of the left-handed and right-handed fermion f , $\ell = 2(T_3 - Qx_W)$, $r = -2Qx_W$, where T_3 is the third component of weak isospin for the left-handed f , Q is its electric charge (in units of the proton charge), and $x_W = \sin^2 \theta_W$:

$$\begin{aligned}
\frac{d\sigma}{dt} &= \frac{2\pi\alpha^2}{N_c s^2} \left\{ \left[\left(Q + \frac{\ell + r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 + \left(\frac{\ell - r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 \right] A(s, t, u) \right. \\
&+ \frac{1}{2x_W} \left(Q + \frac{\ell}{2x_W} \frac{s}{s - m_Z^2} \right) (\Theta(-Q)I(s, t, u) - \Theta(Q)I(s, u, t)) \\
&\left. + \frac{1}{8x_W^2} (\Theta(-Q)E(s, t, u) + \Theta(Q)E(s, u, t)) \right\}, \tag{51.26}
\end{aligned}$$

where $\Theta(x)$ is 1 for $x > 0$ and 0 for $x < 0$, and where

$$\begin{aligned} A(s, t, u) &= \left(\frac{tu}{m_W^4} - 1 \right) \left(\frac{1}{4} - \frac{m_W^2}{s} + 3 \frac{m_W^4}{s^2} \right) + \frac{s}{m_W^2} - 4, \\ I(s, t, u) &= \left(\frac{tu}{m_W^4} - 1 \right) \left(\frac{1}{4} - \frac{m_W^2}{2s} - \frac{m_W^4}{st} \right) + \frac{s}{m_W^2} - 2 + 2 \frac{m_W^2}{t}, \\ E(s, t, u) &= \left(\frac{tu}{m_W^4} - 1 \right) \left(\frac{1}{4} + \frac{m_W^4}{t^2} \right) + \frac{s}{m_W^2}, \end{aligned} \quad (51.27)$$

and s, t, u are the usual Mandelstam variables with $s = (p_f + p_{\bar{f}})^2, t = (p_f - p_{W-})^2, u = (p_f - p_{W+})^2$. The factor N_c is 3 for quarks and 1 for leptons.

The analogous cross-section for $q_i \bar{q}_j \rightarrow W^\pm Z^0$ is

$$\begin{aligned} \frac{d\sigma}{dt} &= \frac{\pi\alpha^2 |V_{ij}|^2}{6s^2 x_W^2} \left\{ \left(\frac{1}{s - m_W^2} \right)^2 \left[\left(\frac{9 - 8x_W}{4} \right) (ut - m_W^2 m_Z^2) \right. \right. \\ &\quad \left. \left. + (8x_W - 6)s(m_W^2 + m_Z^2) \right] \right. \\ &\quad \left. + \left[\frac{ut - m_W^2 m_Z^2 - s(m_W^2 + m_Z^2)}{s - m_W^2} \right] \left[\frac{\ell_j}{t} - \frac{\ell_i}{u} \right] \right. \\ &\quad \left. + \frac{ut - m_W^2 m_Z^2}{4(1 - x_W)} \left[\frac{\ell_j^2}{t^2} + \frac{\ell_i^2}{u^2} \right] + \frac{s(m_W^2 + m_Z^2)}{2(1 - x_W)} \frac{\ell_i \ell_j}{tu} \right\}, \end{aligned} \quad (51.28)$$

where ℓ_i and ℓ_j are the couplings of the left-handed q_i and q_j as defined above. The CKM matrix element between q_i and q_j is V_{ij} .

The cross section for $q_i \bar{q}_i \rightarrow Z^0 Z^0$ is

$$\frac{d\sigma}{dt} = \frac{\pi\alpha^2}{96} \frac{\ell_i^4 + r_i^4}{x_W^2 (1 - x_W^2)^2 s^2} \left[\frac{t}{u} + \frac{u}{t} + \frac{4m_Z^2 s}{tu} - m_Z^4 \left(\frac{1}{t^2} + \frac{1}{u^2} \right) \right]. \quad (51.29)$$

51.5 Production of Higgs Bosons

51.5.1 Resonant Production

The Higgs boson of the Standard Model can be produced resonantly in the collisions of quarks, leptons, W or Z bosons, gluons, or photons. The production cross section is thus controlled by the partial width of the Higgs boson into the entrance channel and its total width. The partial widths are given by the relations

$$\Gamma(H \rightarrow f\bar{f}) = \frac{G_F m_f^2 m_H N_c}{4\pi\sqrt{2}} \left(1 - 4m_f^2/m_H^2 \right)^{3/2}, \quad (51.30)$$

$$\Gamma(H \rightarrow W^+ W^-) = \frac{G_F m_H^3 \beta_W}{32\pi\sqrt{2}} (4 - 4a_W + 3a_W^2), \quad (51.31)$$

$$\Gamma(H \rightarrow ZZ) = \frac{G_F m_H^3 \beta_Z}{64\pi\sqrt{2}} (4 - 4a_Z + 3a_Z^2). \quad (51.32)$$

where N_c is 3 for quarks and 1 for leptons and where $a_W = 1 - \beta_W^2 = 4m_W^2/m_H^2$ and $a_Z = 1 - \beta_Z^2 = 4m_Z^2/m_H^2$. The decay to two gluons proceeds through quark loops, with the t quark dominating. Explicitly,

$$\Gamma(H \rightarrow gg) = \frac{\alpha_s^2 G_F m_H^3}{36\pi^3 \sqrt{2}} \left| \sum_q I(m_q^2/m_H^2) \right|^2, \quad (51.33)$$

where $I(z)$ is complex for $z < 1/4$. For $z < 2 \times 10^{-3}$, $|I(z)|$ is small so the light quarks contribute negligibly. For $m_H < 2m_t$, $z > 1/4$ and

$$I(z) = 3 \left[2z + 2z(1-4z) \left(\sin^{-1} \frac{1}{2\sqrt{z}} \right)^2 \right], \quad (51.34)$$

which has the limit $I(z) \rightarrow 1$ as $z \rightarrow \infty$.

51.5.2 Higgs Boson Production in W^* and Z^* decay

The Standard Model Higgs boson can be produced in the decay of a virtual W or Z (“Higgstrahlung”): In particular, if k is the c.m. momentum of the Higgs boson,

$$\sigma(q_i \bar{q}_j \rightarrow WH) = \frac{\pi \alpha^2 |V_{ij}|^2}{36 \sin^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_W^2}{(s - m_W^2)^2} \quad (51.35)$$

$$\sigma(f \bar{f} \rightarrow ZH) = \frac{2\pi \alpha^2 (\ell_f^2 + r_f^2)}{48 N_c \sin^4 \theta_W \cos^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_Z^2}{(s - m_Z^2)^2}. \quad (51.36)$$

where ℓ and r are defined as above.

51.5.3 W and Z Fusion

Just as high-energy electrons can be regarded as sources of virtual photon beams, at very high energies they are sources of virtual W and Z beams. For Higgs boson production, it is the longitudinal components of the W s and Z s that are important. The distribution of longitudinal W s carrying a fraction y of the electron’s energy is

$$f(y) = \frac{g^2}{16\pi^2} \frac{1-y}{y}, \quad (51.37)$$

where $g = e/\sin \theta_W$. In the limit $s \gg m_H \gg m_W$, the rate $\Gamma(H \rightarrow W_L W_L) = (g^2/64\pi)(m_H^3/m_W^2)$ and in the equivalent W approximation

$$\begin{aligned} \sigma(e^+ e^- \rightarrow \bar{\nu}_e \nu_e H) &= \frac{1}{16m_W^2} \left(\frac{\alpha}{\sin^2 \theta_W} \right)^3 \\ &\times \left[\left(1 + \frac{m_H^2}{s} \right) \log \frac{s}{m_H^2} - 2 + 2 \frac{m_H^2}{s} \right]. \end{aligned} \quad (51.38)$$

There are significant corrections to this relation when m_H is not large compared to m_W . For $m_H = 150$ GeV, the estimate is too high by 51% for $\sqrt{s} = 1000$ GeV, 32% too high at $\sqrt{s} = 2000$ GeV, and 22% too high at $\sqrt{s} = 4000$ GeV. Fusion of ZZ to make a Higgs boson can be treated similarly. Identical formulae apply for Higgs production in the collisions of quarks whose charges permit the emission of a W^+ and a W^- , except that QCD corrections and CKM matrix elements are required. Even in the absence of QCD corrections, the fine-structure constant ought to be evaluated at the scale of the collision, say m_W . All quarks contribute to the ZZ fusion process.¹

¹Further discussion and all references may be found in the full *Review*; the equation and reference numbering corresponds to that version.

52. Neutrino Cross Section Measurements

Revised August 2021 by G.P. Zeller (FNAL).

Highlights from full review.

Neutrino cross sections are an essential ingredient in all neutrino experiments. This work summarizes accelerator-based neutrino cross section measurements performed in the $\sim 0.1 - 300$ GeV range with an emphasis on inclusive, quasi-elastic, and pion production processes, areas where we have the most experimental input at present.

Table 52.1: List of beam properties, nuclear targets, and durations for modern accelerator-based neutrino experiments studying neutrino scattering.

Experiment	beam	$\langle E_\nu \rangle, \langle E_{\bar{\nu}} \rangle$ GeV	neutrino target(s)	run period
ArgoNeuT	$\nu, \bar{\nu}$	4.3, 3.6	Ar	2009 – 2010
ICARUS (at CNGS)	ν	20.0	Ar	2010 – 2012
ICARUS (at FNAL)	ν	0.8	Ar	2021 –
K2K	ν	1.3	CH, H ₂ O	2003 – 2004
MicroBooNE	ν	0.8	Ar	2015 – 2020
MINERvA	$\nu, \bar{\nu}$	3.5 (LE), 5.5 (ME)	He, C, CH, H ₂ O, Fe, Pb	2009 – 2019
MiniBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH ₂	2002 – 2019
MINOS	$\nu, \bar{\nu}$	3.5, 6.1	Fe	2004 – 2016
NOMAD	$\nu, \bar{\nu}$	23.4, 19.7	C-based	1995 – 1998
NOvA	$\nu, \bar{\nu}$	2.0, 2.0	CH ₂	2010 –
SciBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH	2007 – 2008
T2K	$\nu, \bar{\nu}$	0.6, 0.6	CH, H ₂ O, Fe	2010 –

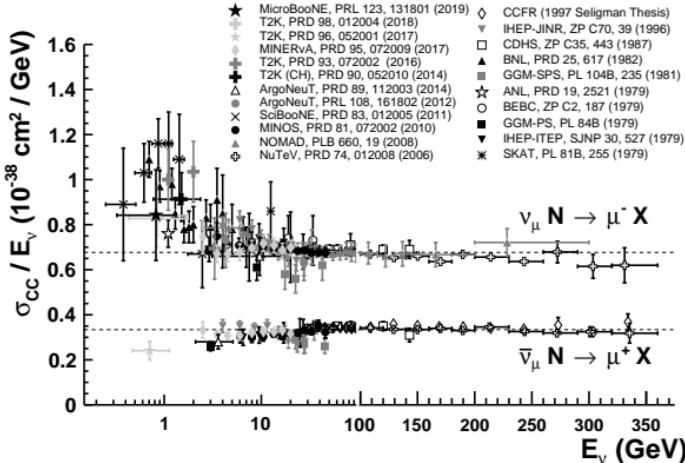

Figure 52.1: Measurements of per nucleon ν_μ and $\bar{\nu}_\mu$ CC inclusive scattering cross sections divided by neutrino energy as a function of neutrino energy. Note the transition between logarithmic and linear scales occurring at 100 GeV.

6. Atomic and Nuclear Properties of Materials

Table 6.1: Abridged from <https://pdg.lbl.gov/AtomicNuclearProperties> by D.E. Groom (2021). See web pages for more detail about entries in this table and for several hundred others. Quantities in parentheses are for gases at 20°C and 1 atm. Boiling points are at 1 atm. Refractive indices n are evaluated at the sodium D line blend (589.2 nm); values $\gg 1$ in brackets indicate $(n - 1) \times 10^6$ for gases at 0°C and 1 atm.

Notes

Table 4.1. Revised June 2021 by D.E. Groom (LBNL). The atomic number (top left) is the number of protons in the nucleus. The atomic masses (bottom) of stable elements are weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of ^{12}C , defined to be exactly 12 unified atomic mass units (u) ($1 \text{ u} \approx 1 \text{ g/mole}$). The exceptions are Th, Pa, and U, which have no stable isotopes but do have characteristic terrestrial compositions. Relative isotopic abundances often vary considerably, both in natural and commercial samples; this is reflected in the number of significant figures given for the mass. Masses may be found at https://physics.nist.gov/cgi-bin/Compositions/stand_alone.pl. If there is no stable isotope, the atomic mass of the most stable isotope known as of June 2019 is given in parentheses.
