Z Boson

Z MASS

OUR AVERAGE is given by the weighted average of the combined CDF result and the combined LEP result, assuming no correlations between CDF and LEP. The combined LEP result, 91.1876 ± 0.0021 GeV, is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). The LEP fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma-Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00Q and ABBIENDI 04G for a detailed investigation of both these issues.

- 1 AALTONEN 22 analyse Z decays in the di-muon and di-electron channels using their full Run-II data set. They obtain Z mass values of $91192.0\pm6.4({\rm stat.})\pm4.0({\rm syst.})$ MeV and $91194.3\pm13.8({\rm stat.})\pm7.6({\rm syst.})$ MeV, respectively. Combining these results using the systematic uncertainty contributions and their correlations as given in AALTONEN 22, we obtain an average of $91192.3\pm5.8({\rm stat.})\pm4.1({\rm syst.})$ MeV.
- ² This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.
- ³ ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.
- 4 ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
- ⁵ ACHARD 04C select $e^+e^- \to Z\gamma$ events with hard initial–state radiation. Z decays to $q\overline{q}$ and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
- ⁶ ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- ⁷ The error includes 1.6 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- ⁸ The error includes 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- 9 ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of ± 2.3 MeV due to the uncertainty on the γZ interference.
- ¹⁰ BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- 11 MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization
- ¹² Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (± 0.93) has two contributions: one (± 0.92) cancels in m_W/m_Z and one (± 0.12) is noncancelling. These were added in quadrature.
- ¹³ First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
- ¹⁴ ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
- 15 ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

Z WIDTH

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $\it Z$ boson" and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included.

¹ JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.

² VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity bias.

 $^{^3}$ ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit-Wigner fits.

⁴ ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.

⁵ The error includes 1.2 MeV due to LEP energy uncertainty.

⁶ The error includes 1.3 MeV due to LEP energy uncertainty.

 $^{^7}$ ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.

⁸BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.

⁹ ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \rightarrow Z \rightarrow \mu^+\mu^-$.

 $^{^{10}}$ ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.

¹¹ ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

 $^{^{12}}$ Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z)<(1.09\pm0.07)\times\Gamma(W),$ CL =90% or $\Gamma(Z)=(0.82^{+}0.19_{-}0.14\pm0.06)\times\Gamma(W).$ Assuming Standard-Model value $\Gamma(W)=2.65$ GeV then gives $\Gamma(Z)<2.89\pm0.19$ or $=2.17^{+}0.50_{-}0.37\pm0.16.$

- [a] ℓ indicates each type of lepton $(e, \mu, \text{ and } \tau)$, not sum over them.
- [b] Here ℓ indicates e or μ .
- [c] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [d] This value is updated using the product of (i) the $Z \to b \, \overline{b}$ fraction from this listing and (ii) the b-hadron fraction in an unbiased sample of weakly decaying b-hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).
- [e] See the Particle Listings below for the γ energy range used in this measurement.

[f] For $m_{\gamma\gamma}=$ (60 \pm 5) GeV.

Z PARTIAL WIDTHS

 $\Gamma(e^+e^-)$ For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06.

 $\Gamma(\ell^+\ell^-)$ ℓ indicates each type of lepton $(e,\,\mu,\,{\rm and}\,\, au)$, not sum over them.

In our fit $\Gamma(\ell^+\ell^-)$ is defined as the partial Z width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

 Γ (invisible) Γ 7

The \vec{Z} boson also decays to final states invisible in any detector, for example, the decay to a neutrino pair as predicted in the Standard Model. Measurements of Γ (invisible) fall into two categories: direct or indirect. Direct measurements look for final states with missing energy, missing momentum, or missing mass, corresponding to the invisible decay of a produced Z boson, including single-photon final states which arise from initial-state radiation. The indirect determination is based on Z lineshape analyses performed at the LEP collider, where the invisible decay width is calculated by subtracting all visible partial decay widths from the total decay width of the Z boson. Within the framework of the Standard Model these two determinations should be identical, but not in non-SM scenarios.

 $^{^1}$ TUMASYAN 23E analyses leptonic Z decay modes, with the invisible Z decay identified by missing momentum.

$\Gamma(\text{hadrons})$

This parameter is not directly used in the 5-parameter fit assuming lepton universality, but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

² The LEP Collaborations perform a combined fit to their line-shape results and determine this quantity as a difference between the total width and the sum of all the visible widths, assuming lepton universality. This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.

 $^{^3}$ This analysis selects single-photon events arising from inital state radiation.

⁴ This is an indirect determination of Γ (invisible) from a fit to the visible Z decay modes. It is included in the determination of the LEP average LEP-SLC 06 reported above.

VALUE	DOCUMENT ID	TECN	COMMENT
1.0010 ± 0.0026 OUR AVERAGE			
1.01 ± 0.05	¹ AAIJ	18AR LHCB	$E_{cm}^{pp} = 8 \; TeV$
1.0010 ± 0.0026	² LEP-SLC	06	$E_{\rm cm}^{ee} = 88-94 \; {\rm GeV}$

 $^{^1}$ AAIJ 18AR obtain the result from the ratio of the measured pp $\to~Z+~X$ cross sections in the corresponding Z decay channels.

 $^{^1}$ AABOUD 17Q make a precise determination of $Z\to e\,e$ and $Z\to \mu\mu$ production in the lepton pseudo-rapidity range $\left|\eta\right|<2.5$ and determine the ratio of the Z branching fractions B(Z $\to e\,e)/$ B(Z $\to \mu\mu)=1.0026\pm0.0013\pm0.0048=1.0026\pm0.0050.$

 $^{^2}$ This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06.

 $\Gamma(\ell^+\ell^-\ell^+\ell^-)/\Gamma_{\text{total}}$

 Γ_6/Γ

Here ℓ indicates either e or μ . The branching fractions in this node are given within the phase-space defined by the requirements that (i) the 4-lepton invariant mass is between 80 GeV and 100 GeV, and (ii) any opposite-sign same-flavor lepton pair has a di-lepton invariant mass larger than 4 GeV.

$VALUE$ (units 10^{-6})	EVTS	DOCUMENT ID	TECN	COMMENT

$4.6 \ ^{+1.0}_{-0.9} \ \pm 0.2$	28	⁵ CHATRCHYAN	I 12BN CMS	$E_{cm}^{pp} = 7 \; TeV$

 $^{^1}$ AAD 21AQ analyze differential cross-sections in four-lepton events. Based on the measured cross section in the $Z\to~4\ell$ channel, a branching fraction of B($Z\to~4\ell$) = (4.41 $\pm~0.13~\pm~0.23~\pm~0.09~\pm~0.12)\times10^{-6}$ is obtained, where the uncertainties are statistical, systematic, theory and luminosity, respectively.

 2 AABOUD 19N reports (4.70 \pm 0.32 \pm 0.21 \pm 0.14) \times 10 $^{-6}$, where the uncertainties are statistical, systematic, and luminosity. We have combined the latter two in quadrature.

 $^{^5}$ CHATRCHYAN 12BN reports $(4.2^{+0.9}_{-0.8}\pm0.2)\times10^{-6}$ value. Their result (both central value and uncertainties) is scaled up by 10% to account for the different phase-space definition used here (see RAINBOLT 19).

- 1 ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events using a double tag method. The single c–tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and R_c is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of ± 0.0006 due to the uncertainty on R_b .
- ² ABREU 00 obtain this result properly combining the measurement from the D^{*+} production rate (R_c = 0.1610 \pm 0.0104 \pm 0.0077 \pm 0.0043 (BR)) with that from the overall charm counting (R_c = 0.1692 \pm 0.0047 \pm 0.0063 \pm 0.0074 (BR)) in $c\overline{c}$ events. The systematic error includes an uncertainty of \pm 0.0054 due to the uncertainty on the charmed hadron branching fractions.
- 3 BARATE 00B use exclusive decay modes to independently determine the quantities $R_c\times {\rm f}(c\to {\rm X}),\,{\rm X}{=}D^0,\,D^+,\,D_s^+,\,{\rm and}\,\Lambda_c.$ Estimating $R_c\times {\rm f}(c\to \Xi_c/\Omega_c){=}$ 0.0034, they simply sum over all the charm decays to obtain $R_c{=}$ 0.1738 \pm 0.0047 \pm 0.0088 \pm 0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, $R_c{=}$ 0.1681 \pm 0.0054 \pm 0.0062) to obtain the quoted value.
- ⁴ ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ± 0.006 due to the external branching ratios.

 $^{
m 5}$ ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0 , D^+ , D_s^+ , and Λ_c^+ , and assuming that strange-charmed baryons account for the 15% of the Λ_c^+ production. An uncertainty of ± 0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics. 6 ABREU 95D perform a maximum likelihood fit to the combined p and $p_{\mathcal{T}}$ distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0124 due to models and branching ratios.

 $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$ OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

The Standard Model predicts R_b =0.21581 for m_t =174.3 GeV and M_H =150 GeV.

- $^{
 m 1}$ ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events using a double tag method. The single b-tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the *D*-meson mass). ABE 05F obtain R_b =0.21604 \pm 0.00098 \pm 0.00074 where the systematic error includes an uncertainty of ± 0.00012 due to the uncertainty on R_c . The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of ± 0.00012 due to the uncertainty on R_c .
- 2 ACCIARRI 00 obtain this result using a double-tagging technique, with a high $p_{\mathcal{T}}$ lepton tag and an impact parameter tag in opposite hemispheres.
- 3 ABBIENDI 99B tag $Z
 ightarrow \ b \, \overline{b}$ decays using leptons and/or separated decay vertices. The b-tagging efficiency is measured directly from the data using a double-tagging technique.
- ⁴ ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For R_c different from its Standard Model value of 0.172, R_b varies as $-0.024 \times (R_c - 0.172)$.
- 5 BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z o b \overline{b}$ candidates. They further use c- and $u\,d\,s$ -selection tags to identify the background. For R_c different from its Standard Model value of 0.172, R_b varies as $-0.019 \times (R_c - 0.172)$.
- 6 ABREU 95D perform a maximum likelihood fit to the combined p and $p_{\mathcal{T}}$ distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0023 due to models and branching ratios.
- 7 BUSKULIC 94G perform a simultaneous fit to the p and $p_{\mathcal{T}}$ spectra of both single and dilepton events.
- 8 JACOBSEN 91 tagged $b\,\overline{b}$ events by requiring coincidence of $\,\geq 3$ tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (± 0.014).

 95 1 SIRUNYAN 19AJ CMS $E_{\rm cm}^{pp}=13$ TeV $<2.3 \times 10^{-6}$ 95 2 AABOUD 18BL ATLS $E_{\rm cm}^{pp}=13$ TeV $<2.6 \times 10^{-6}$ 95 3 AAD 15I ATLS $E_{\rm cm}^{pp}=8$ TeV

- 1 SIRUNYAN 19AJ study $Z\to J/\psi\gamma$ with $J/\psi\to\mu^+\mu^-$. Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is require to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the $\mu\mu~(\mu\mu\gamma)$ system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the Z branching fraction is obtained assuming the J/ψ to be unpolarized.
- 2 AABOUD 18BL study $Z\to J/\psi\,\gamma$ in 13 TeV $p\,p$ interactions. Two triggers were used: isolated photon of $p_T>35(25)$ GeV and a muon with $p_T>18(24)$ GeV. The J/ψ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the J/ψ in the plane transverse to the beam direction is $>\pi/2$. The number of observed/expected background events is $92/89\pm 6$ in the dimuon mass range 2.9--3.3 GeV leading to the quoted 95% C.L. limit.
- ³ AAD 15I use events with the highest p_T muon in the pair required to have $p_T > 20$ GeV, the dimuon mass required to be within 0.2 GeV of the $J/\psi(1S)$ mass and it's transverse momentum required to be > 36 GeV. The photon is also required to have it's $p_T > 36$ GeV.

$\Gamma(J/\psi(1S)\ell^{+}\ell^{-})/\Gamma(\mu^{+}\mu^{-}\mu^{+}\mu^{-})$

 Γ_{30}/Γ_{5}

 $0.67 \pm 0.18 \pm 0.05$

¹SIRUNYAN 18DZ observe the decay $Z \to \Psi \ell^+ \ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV, where Ψ includes J/ψ as well as $\psi(2S) \to J/\psi X$, and $\ell^+\ell^-$ represents an electron or muon pair while the J/ψ is detected via its $\mu^+\mu^-$ decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of $Z \rightarrow$ $\mu^+\mu^-\mu^+\mu^-$ within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and J/ψ transverse momentum. The number of selected $\Psi \mu^+ \mu^-$ ($\Psi e^+ e^-$) candidate events is 29 (18). Analyzing the $\mu^+ \mu^-$ and $\mu^+\mu^-\ell^+\ell^-$ invariant mass distributions, a yield of 13.0 \pm 3.9 (11.2 \pm 3.4) events for the $\psi\mu^+\mu^-$ (ψe^+e^-) mode is obtained. The ratio of the branching fractions is determined as $0.67 \pm 0.18 \pm 0.05$ within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of $B(Z \to \mu^+ \mu^- \mu^+ \mu^-) = (1.20 \pm 0.08) \times 10^{-6}$, they estimate $B(Z \to J/\psi \ell^+ \ell^-)$ $= 8 \times 10^{-7}$

$\Gamma(D_{s1}(2536)^{\pm}X)/\Gamma(\text{hadrons})$

 Γ_{46}/Γ_{8}

 $D_{s1}(2536)^{\pm}$ is an expected orbitally-excited state of the D_s meson.

VALUE (%)	EVTS	DOCUMENT ID		TECN	COMMENT
0.52±0.09±0.06	92	¹ HEISTER	02 B	ALEP	E ^{ee} _{cm} = 88–94 GeV

 $^{^1}$ HEISTER 02B reconstruct this meson in the decay modes $D_{s1}(2536)^\pm \to D^{*\pm} K^0$ and $D_{s1}(2536)^\pm \to D^{*0} K^\pm$. The quoted branching ratio assumes that the decay width of the $D_{s1}(2536)$ is saturated by the two measured decay modes.

$\Gamma(D_{sJ}(2573)^{\pm}X)/\Gamma(\text{hadrons})$

 Γ_{47}/Γ_{8}

Created: 4/29/2024 18:59

 D_{sJ} (2573) $^{\pm}$ is an expected orbitally-excited state of the D_{s} meson.

VALUE (%)EVTSDOCUMENT IDTECNCOMMENT $0.83 \pm 0.29 ^{+0.07}_{-0.13}$ 641 HEISTER02BALEP $E^{ee}_{cm} = 88-94$ GeV

 $^{^1}$ AAIJ 23AM also quotes the branching fraction limit B($Z \to D^0 \gamma$) $< 2.1 \times 10^{-3}$, using the known $Z \to \mu\mu$ branching fraction.

 $^{^1}D^*(2010)^\pm$ in ABREU 93I are reconstructed from $D^0\pi^\pm$, with $D^0\to K^-\pi^+$. The new CLEO II measurement of B($D^{*\pm}\to D^0\pi^\pm$) = (68.1 \pm 1.6) % is used. This is a corrected result (see the erratum of ABREU 93I).

² DECAMP 91J report B($D^*(2010)^+ \to D^0\pi^+$) B($D^0 \to K^-\pi^+$) $\Gamma(D^*(2010)^\pm X)$ / $\Gamma(\text{hadrons}) = (5.11 \pm 0.34) \times 10^{-3}$. They obtained the above number assuming B($D^0 \to K^-\pi^+$) = (3.62 \pm 0.34 \pm 0.44)% and B($D^*(2010)^+ \to D^0\pi^+$) = (55 \pm 4)%. We have rescaled their original result of 0.26 \pm 0.05 taking into account the new CLEO II branching ratio B($D^*(2010)^+ \to D^0\pi^+$) = (68.1 \pm 1.6)%.

 $^{^1}$ HEISTER 02B reconstruct this meson in the decay mode $D_{s2}^*(2573)^\pm \to D^0 \, K^\pm$. The quoted branching ratio assumes that the detected decay mode represents 45% of the full decay width.

$\Gamma(D^{*\prime}(2629)^{\pm}X)/\Gamma(\text{hadrons})$

 Γ_{48}/Γ_{8}

 $D^{*\prime}(2629)^{\pm}$ is a predicted radial excitation of the $D^{*}(2010)^{\pm}$ meson.

The first error is the total experiment's error and the second error is the systematic error due to the branching fraction uncertainty.
- ² BUSKULIC 96Y obtain the production fraction of Λ_c^+ baryons in hadronic Z decays $f(b \to \Lambda_c^+ X) = 0.110 \pm 0.014 \pm 0.006$ using $B(\Lambda_c^+ \to p K^- \pi^+) = (4.4 \pm 0.6)\%$; we have rescaled using our best value $B(\Lambda_c^+ \to p K^- \pi^+) = (5.0 \pm 1.3)\%$ obtaining $f(b \to \Lambda_c^+ X) = 0.097 \pm 0.013 \pm 0.025$ where the first error is their total experiment's error and the second error is the systematic error due to the branching fraction uncertainty. The value quoted here is obtained multiplying this production fraction by our value of $R_b = \Gamma(b \, \overline{b})/\Gamma(\text{hadrons})$.

$\Gamma(\Xi_c^0 X)/\Gamma(hadrons)$

 Γ_{55}/Γ_{8}

ALUE <u>DOCUMENT ID</u> <u>TECN</u> <u>COMMENT</u>

 \bullet \bullet We do not use the following data for averages, fits, limits, etc. \bullet \bullet

seen 1 ABDALLAH 05C DLPH $E_{cm}^{ee} = 88-94$ GeV

 1 ABDALLAH 05C searched for the charmed strange baryon Ξ_c^0 in the decay channel $\Xi_c^0 \to \Xi^-\pi^+ \ (\Xi^- \to \Lambda\pi^-)$. The production rate is measured to be $f_{\Xi_c^0} \times \ {\rm B}(\Xi_c^0 \to \Xi^-\pi^+) = (4.7 \pm 1.4 \pm 1.1) \times 10^{-4}$ per hadronic Z decay.

$\Gamma(\Xi_b X)/\Gamma(hadrons)$

[⁻]56/Г8

Created: 4/29/2024 18:59

Here Ξ_b is used as a notation for the strange b-baryon states Ξ_b^- and Ξ_b^0 .

• • We do not use the following data for averages, fits, limits, etc. • •

seen 1 ABDALLAH 0 05C DLPH ee 0 88–94 GeV seen 2 BUSKULIC 0 96T ALEP ee 0 88–94 GeV seen 3 ABREU 0 95V DLPH ee 0 88–94 GeV

- ¹ ABDALLAH 05C searched for the beauty strange baryon Ξ_b in the inclusive semileptonic decay channel $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell X$. Evidence for the Ξ_b production is seen from the observation of Ξ^\mp production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$ the production rate is measured to be B($b \to \Xi_b$) \times B($\Xi_b \to \Xi^- \ell^- X$) = (3.0 \pm 1.0 \pm 0.3) \times 10⁻⁴ per lepton species, averaged over electrons and muons.
- ²BUSKULIC 96T investigate Ξ -lepton correlations and find a significant excess of "right-sign" pairs $\Xi^{\mp}\ell^{\mp}$ compared to "wrong-sign" pairs $\Xi^{\mp}\ell^{\pm}$. This excess is interpreted as evidence for Ξ_b semileptonic decay. The measured product branching ratio is B($b \to \Xi_b$) \times B($\Xi_b \to X_c X \ell^- \overline{\nu}_\ell$) \times B($X_c \to \Xi^- X'$) = (5.4 \pm 1.1 \pm 0.8) \times 10⁻⁴ per lepton species, averaged over electrons and muons, with X_c a charmed baryon.
- ³ ABREU 95V observe an excess of "right-sign" pairs $\Xi^{\mp}\ell^{\mp}$ compared to "wrong-sign" pairs $\Xi^{\mp}\ell^{\pm}$ in jets: this excess is interpreted as evidence for the beauty strange baryon Ξ_b production, with $\Xi_b \to \Xi^-\ell^-\overline{\nu}_\ell X$. They find that the probability for this signal to come from non b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events. The Ξ_b production rate is then measured to be $B(b \to \Xi_b) \times B(\Xi_b \to \Xi^-\ell^- X) = (5.9 \pm 2.1 \pm 1.0) \times 10^{-4}$ per lepton species, averaged over electrons and muons.

 $\Gamma(b$ -baryon X)/ $\Gamma(hadrons)$

$2.40 \pm 0.06 \pm 0.43$	ACKERSTAFE 08A	ΩΡΔΙ	Fee - 91.2 GeV

 $^{^{1}}$ BEDDALL 09 analyse 3.2 million hadronic Z decays as archived by ALEPH collaboration and report a value of 2.59 \pm 0.03 \pm 0.15 \pm 0.04. The first error is statistical, the second systematic, and the third arises from extrapolation to full phase space. We combine the systematic errors in quadrature.

Z HADRONIC POLE CROSS SECTION

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $\it Z$ boson" and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included. This quantity is defined as

$$\sigma_h^0 = rac{12\pi}{M_Z^2} \; rac{\Gamma(e^+\,e^-)\,\Gamma(ext{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

- ¹ JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.
- ² VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity
- ³ ABBIENDI 01A error includes approximately 0.031 due to statistics, 0.033 due to event selection systematics, 0.029 due to uncertainty in luminosity measurement, and 0.011 due to LEP energy uncertainty.
- ⁴BARATE 00C error includes approximately 0.030 due to statistics, 0.026 due to experimental systematics, and 0.025 due to uncertainty in luminosity measurement.

Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e , A_μ , and A_τ . By convention the sign of g_A^e is fixed to be negative (and opposite to that of $g^{\nu}e$ obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e , A_μ , and A_τ measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p_{\overline{p}}$ and $e_{\overline{p}}$ data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

<u>VALUE</u>	<u>DOCUMENT ID</u>		TECN	COMMENT
0.502±0.017	1 VILAIN	94	CHM2	From $\nu_{\mu} e$ scattering

 1 VILAIN 94 derive this value from their measurement of the couplings $g_A^{e\,\nu_\mu}=-0.503\pm0.017$ and $g_V^{e\,\nu_\mu}=-0.035\pm0.017$ obtained from $\nu_\mu\,e$ scattering. We have re-evaluated this value using the current PDG values for g_A^e and g_V^e .

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

¹ ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in $\mu^+\mu^-$ decays of the Z boson obtained with a polarized electron beam.

² AAD 15BT study $pp \to Z \to \ell^+\ell^-$ events where ℓ is an electron or a muon in the dilepton mass region 70–1000 GeV. The background in the Z peak region is estimated to be < 1% for the muon channel. The muon asymmetry parameter is derived from the measured forward-backward asymmetry assuming the value of the quark asymmetry parameter from the SM. For this reason it is not used in the average.

The LEP Collaborations derive this quantity from the measurement of the τ polarization in $Z \to \tau^+ \tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z \to \tau^+ \tau^-$ produced using a polarized e^- beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e .

0.670 ± 0.027 OUR FIT				
$0.6712 \pm 0.0224 \pm 0.0157$	$^{ m 1}$ ABE	05	SLD	$E_{\rm cm}^{\it ee}=$ 91.24 GeV
• • • We do not use the followi	ng data for ave	rages, fits,	limits,	etc. • • •
$0.583 \pm 0.055 \pm 0.055$	² ABE	02 G	SLD	E ^{ee} _{cm} = 91.24 GeV
0.688 ± 0.041	³ ABE	01 C	SLD	$E_{\mathrm{cm}}^{\mathrm{ee}} = 91.25 \; \mathrm{GeV}$

 $^{^1}$ ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\,\overline{c}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events) $A_{C}=0.6747\pm0.0290\pm0.0233$. Taking into account all correlations with earlier results reported in ABE 02G and ABE 01C, they obtain the quoted overall SLD result.

³ ABE 01C tag $Z \to c \, \overline{c}$ events using two techniques: exclusive reconstruction of D^{*+} , D^+ and D^0 mesons and the soft pion tag for $D^{*+} \to D^0 \pi^+$. The large background from D mesons produced in $b \, \overline{b}$ events is separated efficiently from the signal using precision vertex information. When combining the A_C values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $b\overline{b}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e . OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

 $^{^1}$ ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\,\overline{b}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events) $A_b=0.9173\pm0.0184\pm0.0173.$ Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.

 $^{^2}$ ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c

 $^{^2}$ ABE 03F obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying b quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure $A_b=0.906\pm0.022\pm0.023$. The value quoted here is obtained combining the above with the result of ABE 98I (1993–1995 data sample).

TRANSVERSE SPIN CORRELATIONS IN $Z \rightarrow \tau^+ \tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^{\tau}|^2 - |g_V^{\tau}|^2}{|g_A^{\tau}|^2 + |g_V^{\tau}|^2}$$

$$C_{TN} = -2 \frac{|g_A^{\tau}| |g_V^{\tau}|}{|g_A^{\tau}|^2 + |g_V^{\tau}|^2} \sin(\Phi_{g_V^{\tau}} - \Phi_{g_A^{\tau}})$$

 C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal τ polarization P_{τ} $(=-A_{\tau})$ is given by:

$$P_{\tau} = -2 \frac{|g_A^{\tau}||g_V^{\tau}|}{|g_A^{\tau}|^2 + |g_V^{\tau}|^2} \cos(\Phi_{g_V^{\tau}} - \Phi_{g_A^{\tau}})$$

Here Φ is the phase and the phase difference $\Phi_{\mathcal{G}_{V}^{\mathcal{T}}} - \Phi_{\mathcal{G}_{A}^{\mathcal{T}}}$ can be obtained using both the measurements of C_{TN} and $P_{\mathcal{T}}$.

$A_{FB}^{(0, au)}$ CHARGE ASYMMETRY IN $e^+e^ightarrow~ au^+ au^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). For the Z peak, we report the pole asymmetry defined by $(3/4)A_{\rm e}A_{\rm T}$ as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

- ¹ ABDALLAH 05 obtain an enriched samples of $b\overline{b}$ events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.
- ² ABDALLAH 04F tag b- and c-quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.
- ³ ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0 - \overline{B}^0 mixing.
- ⁴ ABBIENDI 02I tag $Z^0 \to b\overline{b}$ decays using a combination of secondary vertex and lepton tags. The sign of the *b*-quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.
- 5 HEISTER 02H measure simultaneously b and c quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.
- ⁶ HEISTER 01D tag $Z \rightarrow b \, \overline{b}$ events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The b-quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of A_{FB}^c and R_b is given as +0.103 ($A_{FB}^c 0.0651$) -0.440 ($R_b 0.21585$).
- ⁷ ABREU 99Y tag $Z \rightarrow b\overline{b}$ and $\overline{Z} \rightarrow c\overline{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+} , D^0 , and D^+ with their charge-conjugate states).
- ⁸ ACCIARRI 99D tag $Z \to b \, \overline{b}$ events using high p and p_T leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.
- ⁹ ACCIARRI 980 tag $Z \rightarrow b\overline{b}$ events using lifetime and measure the jet charge using the hemisphere charge.

CHARGE ASYMMETRY IN $e^+e^- \rightarrow q\overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B^0 - \overline{B}^0 mixing and on other electroweak parameters.

ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND ZZV COUPLINGS

Revised September 2013 by M.W. Grünewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell $Z\gamma$ production, deviations from the Standard Model for the $Z\gamma\gamma^*$ and $Z\gamma Z^*$ couplings may be described in terms of eight parameters, h_i^V ($i=1,4;\ V=\gamma,Z$) [1]. The parameters h_i^γ describe the $Z\gamma\gamma^*$ couplings and the parameters h_i^Z the $Z\gamma Z^*$ couplings. In this formalism h_1^V and h_2^V lead to CP-violating and h_3^V and h_4^V to CP-conserving effects. All these anomalous contributions to the cross section increase

 $^{^2}$ ACTON 92L use the weight function method on 259k selected $Z\to$ hadrons events. The systematic error includes a contribution of 0.2 due to B^0 - $\overline B{}^0$ mixing effect, 0.4 due to Monte Carlo (MC) fragmentation uncertainties and 0.3 due to MC statistics. ACTON 92L derive a value of $\sin^2\!\theta_W^{\rm eff}$ to be 0.2321 \pm 0.0017 \pm 0.0028.

rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{i\circ}^V/(1+s/\Lambda^2)^n$, where Λ is the energy scale for the manifestation of a new phenomenon and n is a sufficiently large power. By convention one uses n=3 for $h_{1,3}^V$ and n=4 for $h_{2,4}^V$. Usually limits on h_i^V 's are put assuming some value of Λ , sometimes ∞ .

In on-shell ZZ production, deviations from the Standard Model for the $ZZ\gamma^*$ and ZZZ^* couplings may be described by means of four anomalous couplings f_i^V $(i=4,5;V=\gamma,Z)$ [2]. As above, the parameters f_i^{γ} describe the $ZZ\gamma^*$ couplings and the parameters f_i^Z the ZZZ^* couplings. The anomalous couplings f_5^V lead to violation of C and P symmetries while f_4^V introduces CP violation. Also here, formfactors depending on a scale Λ are used.

All these couplings h_i^V and f_i^V are zero at tree level in the Standard Model; they are measured in e^+e^- , $p\bar{p}$ and pp collisions at LEP, Tevatron and LHC.

 h_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$\begin{array}{lll} -0.12 < h_1^Z < +0.11, & -0.07 < h_2^Z < +0.07, \\ -0.19 < h_3^Z < +0.06, & -0.04 < h_4^Z < +0.13, \\ -0.05 < h_1^\gamma < +0.05, & -0.04 < h_2^\gamma < +0.02, \\ -0.05 < h_3^\gamma < +0.00, & +0.01 < h_4^\gamma < +0.05. \end{array}$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

 1 AAD 16Q study $Z\gamma$ production in pp collisions. In events with no additional jets, 10268 (12738) Z decays to electron (muon) pairs are selected, with an expected background of 1291 \pm 340 (1537 \pm 408) events, as well as 1039 Z decays to neutrino pairs with an expected background of 450 \pm 96 events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-7.8\times10^{-4} < h_3^Z < 8.6\times10^{-4}, -3.0\times10^{-6} < h_4^Z < 2.9\times10^{-6}, -9.5\times10^{-4} < h_3^\gamma < 9.9\times10^{-4}, -3.2\times10^{-6} < h_4^\gamma < 3.2\times10^{-6}.$

 2 KHACHATRYAN 16AE determine the $Z\gamma \to \nu \overline{\nu} \gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and $E_T > 140$ GeV. 630 candidate events are observed with an expected SM background of 269 ± 26 . The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $-1.5 \times 10^{-3} < h_3^Z < 1.6 \times 10^{-3}, -3.9 \times 10^{-6} < h_4^Z < 4.5 \times 10^{-6}, -1.1 \times 10^{-3} < h_3^\gamma < 0.9 \times 10^{-3}, -3.8 \times 10^{-6} < h_4^\gamma < 4.3 \times 10^{-6}.$

 3 KHACHATRYAN 15AC study $Z\gamma$ events in 8 TeV pp interactions, where the Z decays into 2 same-flavor, opposite sign leptons (e or μ) and a photon with $p_T>15$ GeV. The p_T of a lepton is required to be >20 GeV/c, their effective mass >50 GeV, and the photon should have a separation $\Delta R>0.7$ with each lepton. The observed p_T distribution of the photons is used to extract the 95% C.L. limits: $-3.8\times 10^{-3}< h_3^Z<3.7\times 10^{-3}, -3.1\times 10^{-5}< h_4^Z<3.0\times 10^{-5}, -4.6\times 10^{-3}< h_3^\gamma<4.6\times 10^{-3}, -3.6\times 10^{-5}< h_4^N<3.5\times 10^{-5}.$

 4 CHATRCHYAN 14AB measure $Z\gamma$ production cross section for ${\rm p}_T^\gamma>15$ GeV and R($\ell\gamma)>0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity $(\phi-\eta)$ plane. The di-lepton mass is required to be >50 GeV. After background subtraction the number of $e\,e\gamma$ and $\mu\mu\gamma$ events is determined to be 3160 ± 120 and 5030 ± 233 respectively, compatible with expectations from the SM. This leads to a 95% CL limits of -1×10^{-2} < h_3^γ < 1×10^{-2} , -9×10^{-5} < h_4^γ < 9×10^{-5} , -9×10^{-3} < h_3^Z < 9×10^{-3} , -8×10^{-5} < h_4^Z < 8×10^{-5} , assuming h_1^V and h_2^V have SM values, $V=\gamma$ or Z.

⁵ AAD 13AN study $Z\gamma$ production in pp collisions. In events with no additional jet, 1417 (2031) Z decays to electron (muon) pairs are selected, with an expected background of

- $156 \pm 54 \ (244 \pm 64)$ events, as well as $662 \ Z$ decays to neutrino pairs with an expected background of 302 ± 42 events. Analysing the photon p_T spectrum above $100 \ \text{GeV}$ yields the 95% C.L. limts: $-0.013 \ < \ h_3^Z \ < 0.014, \ -8.7 \times 10^{-5} \ < \ h_4^Z \ < \ 8.7 \times 10^{-5}, \ -0.015 \ < \ h_3^{\gamma} \ < 0.016, \ -9.4 \times 10^{-5} \ < \ h_4^{\gamma} \ < \ 9.2 \times 10^{-5}.$ Supersedes AAD 12BX.
- 6 CHATRCHYAN 13BI determine the $Z\gamma \to \nu \overline{\nu} \gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and a $E_T > 130$ GeV. 73 candidate events are observed with an expected SM background of 30.2 ± 6.5 . The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $\left|h_3^Z\right| < 2.7 \times 10^{-3}, \left|h_4^Z\right| < 1.3 \times 10^{-5}, \left|h_3^{\gamma}\right| < 2.9 \times 10^{-3}, \left|h_4^{\gamma}\right| < 1.5 \times 10^{-5}.$
- ⁷ ABAZOV 12S study $Z\gamma$ production in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV using 6.2 fb⁻¹ of data where the Z decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255 ± 16 (285 ± 24) events. Based on the photon p_T spectrum, and including also earlier data and the $Z\to \nu\overline{\nu}$ decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported: $|h_{03}^Z|<0.026, |h_{04}^Z|<0.0013, |h_{03}^\gamma|<0.027, |h_{04}^\gamma|<0.0014$ for a form factor scale of Λ = 1.5 TeV.
- ⁸ AALTONEN 11s study $Z\gamma$ events in $p\overline{p}$ interactions at $\sqrt{s}=1.96$ TeV with integrated luminosity 5.1 fb $^{-1}$ for $Z\to e^+e^-/\mu^+\mu^-$ and 4.9 fb $^{-1}$ for $Z\to \nu\overline{\nu}$. For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one >20 GeV and the other >10 GeV. The isolated photon must have $E_T>50$ GeV. They observe 91 events with 87.2 \pm 7.8 events expected from standard model processes. For the $\nu\overline{\nu}$ case they require solitary photons with $E_T>25$ GeV and missing $E_T>25$ GeV and observe 85 events with standard model expectation of 85.9 \pm 5.6 events. Taking the form factor $\Lambda=1.5$ TeV they derive 95% C.L. limits as $|h_3^{\gamma}, Z|<0.022$ and $|h_4^{\gamma}, Z|<0.0009$.
- ⁹ CHATRCHYAN 11M study $Z\gamma$ production in pp collisions at $\sqrt{s}=7$ TeV using $36~{\rm pb}^{-1}$ pp data, where the Z decays to e^+e^- or $\mu^+\mu^-$. The total cross sections are measured for photon transverse energy $E_T^\gamma>10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma)>0.7$ with the dilepton invariant mass requirement of $M_{\ell\ell}>50$ GeV. The number of $e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ candidates is 81 and 90 with estimated backgrounds of 20.5 ± 2.5 and 27.3 ± 3.2 events respectively. The 95% CL limits for $ZZ\gamma$ couplings are $-0.05< h_3^Z<0.06$ and $-0.0005< h_4^Z<0.0005$, and for $Z\gamma\gamma$ couplings are $-0.07< h_3^\gamma<0.07$ and $-0.0005< h_4^\gamma<0.0006$.
- 10 ABAZOV 09L study $Z\gamma,\,Z\to\,\nu\overline{\nu}$ production in $p\overline{p}$ collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy E_T larger than 90 GeV, with an expected background of 17 events. Based on the photon E_T spectrum and including also Z decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported: $|h_{30}^{\gamma}|<0.033,\,|h_{40}^{\gamma}|<0.0017,\,|h_{30}^{Z}|<0.033,\,|h_{40}^{Z}|<0.0017.$
- 11 ABAZOV 07M use 968 $p\overline{p}\to {\rm e^+\,e^-/\mu^+\,\mu^-}\,\gamma X$ candidates, at 1.96 TeV center of mass energy, to tag $p\overline{p}\to Z\gamma$ events by requiring $E_T(\gamma)\!>\!7$ GeV, lepton-gamma separation $\Delta {\rm R}_{\ell\gamma}\!>\!0.7$, and di-lepton invariant mass > 30 GeV. The cross section is in agreement with the SM prediction. Using these $Z\gamma$ events they obtain 95% C.L. limits on each h_i^V , keeping all others fixed at their SM values. They report: $-0.083 < h_{30}^Z < 0.082$, $-0.0053 < h_{40}^Z < 0.0054$, $-0.085 < h_{30}^\gamma < 0.084$, $-0.0053 < h_{40}^\gamma < 0.0054$, for the form factor scale $\Lambda\!=\!1.2$ TeV.
- ¹² Using data collected at $\sqrt{s}=183$ –208, ABDALLAH 07C select 1,877 $e^+e^- \rightarrow Z\gamma$ events with $Z \rightarrow q \overline{q}$ or $\nu \overline{\nu}$, 171 $e^+e^- \rightarrow ZZ$ events with $Z \rightarrow q \overline{q}$ or lepton pair

(except an explicit au pair), and 74 $e^+e^- o Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on h_i^V . Each limit is derived with other parameters set to zero. They report: $-0.23 < h_1^Z < 0.23, \, -0.30 < h_3^Z < 0.16, \, -0.14 < h_1^\gamma < 0.14, \, -0.049 < h_3^\gamma < 0.044.$

- ^{13} ACHARD 04H select 3515 $e^+e^- o Z\gamma$ events with $Z o q \overline{q}$ or $\nu \overline{\nu}$ at $\sqrt{s} = 189$ –209 GeV to derive 95% CL limits on h_i^V . For deriving each limit the other parameters are fixed at zero. They report: $-0.153 < h_1^Z < 0.141, -0.087 < h_2^Z < 0.079, -0.220 < h_3^Z < 0.112, -0.068 < h_4^Z < 0.148, -0.057 < h_1^{\gamma} < 0.057, -0.050 < h_2^{\gamma} < 0.023, -0.059 < h_3^{\gamma} < 0.004, -0.004 < h_4^{\gamma} < 0.042.$
- 14 ABBIENDI,G 00C study $e^+e^- \rightarrow Z\gamma$ events (with $Z \rightarrow q\overline{q}$ and $Z \rightarrow \nu\overline{\nu}$) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings: $h_1^Z = 0.000 \pm 0.100 \; (-0.190, 0.190), \; h_2^Z = 0.000 \pm 0.068 \; (-0.128, 0.128), \; h_3^Z = -0.074^{+0.102}_{-0.103} \; (-0.269, 0.119), \; h_4^Z = 0.046 \pm 0.068 \; (-0.084, 0.175), \; h_1^{\gamma} = 0.000 \pm 0.061 \; (-0.115, 0.115), \; h_2^{\gamma} = 0.000 \pm 0.041 \; (-0.077, 0.077), \; h_3^{\gamma} = -0.080^{+0.039}_{-0.041} \; (-0.164, -0.006), \; h_4^{\gamma} = 0.064^{+0.033}_{-0.030} \; (+0.007, +0.134). \;$ The results are derived assuming that only one coupling at a time is different from zero.
- \$\$ ABBOTT 98M study \$\$ \$p \overline{p} \to Z \gamma + X\$, with \$Z \to e^+ e^-\$, \$\$ \$\mu^+ \mu^-\$, \$\overline{v} \nu\$ at 1.8 TeV, to obtain 95% CL limits at \$\Lambda = 750 \text{ GeV}\$: \$\$ \$|h_{30}^Z| < 0.36\$, \$\$|h_{40}^Z| < 0.05\$ (keeping \$h_i^{\gamma} = 0\$)\$, and \$\$|h_{30}^{\gamma}| < 0.37\$, \$\$|h_{40}^{\gamma}| < 0.05\$ (keeping \$h_i^{Z} = 0\$)\$. Limits on the \$CP\$-violating couplings are \$\$|h_{10}^Z| < 0.36\$, \$\$|h_{20}^Z| < 0.05\$ (keeping \$h_i^{\gamma} = 0\$)\$, and \$\$|h_{10}^{\gamma}| < 0.37\$, \$\$|h_{20}^{\gamma}| < 0.05\$ (keeping \$h_i^{Z} = 0\$)\$.
- ¹⁶ ABREU 98K determine a 95% CL upper limit on $\sigma(e^+e^- \to \gamma + \text{invisible particles}) < 2.5 pb using 161 and 172 GeV data. This is used to set 95% CL limits on <math>|h_{30}^{\gamma}| < 0.8$ and $|h_{30}^{Z}| < 1.3$, derived at a scale $\Lambda = 1$ TeV and with n = 3 in the form factor representation.

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.28 < f_4^Z < +0.32,$$
 $-0.34 < f_5^Z < +0.35,$ $-0.17 < f_4^{\gamma} < +0.19,$ $-0.35 < f_5^{\gamma} < +0.32.$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

- 1 AAD 23CH measure ZZ production with the Z bosons decaying to electrons or muons. Analysing the angular information of the final-state four-lepton system, the following limits are derived at 95% C.L.: -0.012 < f_4^Z < 0.012, -0.015 < f_4^γ < 0.015.
- 2 SIRUNYAN 21Q measure ZZ production where both Z bosons decay in the electron or muon channel. Analyzing the four-lepton invariant mass distribution, the following limits are derived at 95% C.L. in units of 10^{-4} : $-6.6 < f_4^Z < 6.0, -5.5 < f_5^Z < 7.5, -7.8 < <math display="inline">f_4^\gamma < 7.1, -6.8 < f_5^\gamma < 7.5$. This set of parameters is linearly related to a set of EFT parameters, resulting in the following limits at 95% C.L. in units of TeV $^{-4}$: $-2.3 < c_{\widetilde{B}W}/\Lambda^4 < 2.5, -1.4 < c_{WW}/\Lambda^4 < 1.2, -1.4 < c_{BW}/\Lambda^4 < 1.3, -1.2 < c_{BB}/\Lambda^4 < 1.2.$
- ³AABOUD 19AY study ZZ production in the $\ell\ell\nu\nu$ decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (dimuon) events are found, with a total expected background of 128 ± 8 (143 ± 8) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of 10^{-3} : $-1.2 < f_4^{\gamma} < 1.2, -1.0 < f_4^{Z} < 1.0, -1.2 < f_5^{\gamma} < 1.2, -1.0 < f_5^{Z} < 1.0$.
- ⁴ AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s}=13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the 4e, 2e 2μ , and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of 10^{-4} : $-1.8 < f_4^{\gamma} < 1.8$, $-1.5 < f_4^{Z} < 1.5$, $-1.8 < f_5^{\gamma} < 1.8$, $-1.5 < f_5^{Z} < 1.5$.
- 5 SIRUNYAN 18BT study ppZZ events at $\sqrt{s}=13$ TeV with $Z\to e^+e^-$ or $Z\to \mu^+\mu^-$. The number of events observed in the 4e, $2e2\mu$, and 4μ channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of 10^{-3} : $-1.2 < f_4^\gamma < 1.3, -1.2 < f_4^Z < 1.0, -1.2 < f_5^\gamma < 1.3, -1.0 < f_5^Z < 1.3.$
- 6 KHACHATRYAN 15B study ZZ production in 8 TeV $p\,p$ collisions. In the decay modes $ZZ\to 4e,\,4\mu,\,2e\,2\mu,\,54,\,75,\,148$ events are observed, with an expected background of $2.2\pm0.9,\,1.2\pm0.6,\,$ and 2.4 ± 1.0 events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained: $\left|f_4^Z\right|\,<0.004,\,\left|f_5^Z\right|\,<0.004,\,\left|f_4^\gamma\right|\,<0.005,\,\left|f_5^\gamma\right|\,<0.005.$
- 7 KHACHATRYAN 15BC use the cross section measurement of the final state $p\,p\to Z\,Z\to 2\ell 2\nu$, (ℓ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T>$ 45 GeV. The reduced missing E_T is required to be > 65 GeV, which takes into account the fake missing E_T due to detector effects. The numbers of $e^+\,e^-$ and $\mu^+\,\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement

with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032$, $-0.0037 < f_4^\gamma < 0.0033$, $-0.0029 < f_5^Z < 0.0031$, $-0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \to ZZ \to 2\ell 2\ell'$ where ℓ and ℓ' are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026$, $-0.0029 < f_4^\gamma < 0.0026$, $-0.0023 < f_5^Z < 0.0023$, $-0.0026 < f_5^\gamma < 0.0027$.

- ⁸ AAD 13Z study ZZ production in pp collisions at $\sqrt{s}=7$ TeV. In the $ZZ\to \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of 0.9 ± 1.3 . In the $ZZ\to \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of 46.9 ± 5.2 . The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in p^Z_T . The 95% C.L. are as follows: for form factor scale $\Lambda=\infty$, -0.015 < f^γ_4 < 0.015, -0.013 < f^Z_5 < 0.013, -0.016 < f^γ_5 < 0.015, -0.013 < f^Z_5 < 0.013; for form factor scale $\Lambda=3$ TeV, -0.022 < f^γ_4 < 0.023, -0.019 < f^Z_4 < 0.019, -0.023 < f^γ_5 < 0.023, -0.020 < f^ζ_5 < 0.019.
- ⁹ CHATRCHYAN 13B study ZZ production in pp collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of 1.4 ± 0.5 events. The resulting 95% C.L. ranges are: $-0.013 < f_4^{\gamma} < 0.015, -0.011 < f_4^{Z} < 0.012, -0.014 < f_5^{\gamma} < 0.014, -0.012 < f_5^{Z} < 0.012.$
- 10 Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+\,e^-\to~ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^\gamma < 0.318, \, -0.534 < f_4^Z < 0.534, \, -0.724 < f_5^\gamma < 0.733, \, -1.194 < f_5^Z < 1.190.$
- 11 ABAZOV 08K search for ZZ and $Z\gamma^*$ events with $1\,\mathrm{fb}^{-1}$ $p\overline{p}$ data at $\sqrt{s}=1.96$ TeV in $(e\,e)(e\,e),\,(\mu\mu)(\mu\mu),\,(e\,e)(\mu\mu)$ final states requiring the lepton pair masses to be >30 GeV. They observe 1 event, which is consistent with an expected signal of 1.71 ± 0.15 events and a background of 0.13 ± 0.03 events. From this they derive the following limits, for a form factor (Λ) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28,\, -0.31 < f_{50}^Z < 0.29,\, -0.26 < f_{40}^\gamma < 0.26,\, -0.30 < f_{50}^\gamma < 0.28.$
- Using data collected at $\sqrt{s}=183$ –208 GeV, ABDALLAH 07C select 171 $e^+e^- \to ZZ$ events with $Z \to q \overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q \overline{q} \mu^+ \mu^-$ or $q \overline{q} e^+ e^-$ signature, to derive 95% CL limits on f_i^V . Each limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42$, $-0.38 < f_5^Z < 0.62$, $-0.23 < f_4^\gamma < 0.25$, $-0.52 < f_5^\gamma < 0.48$.
- ¹³ ABBIENDI 04C study ZZ production in e^+e^- collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58$, $-0.94 < f_5^Z < 0.25$, $-0.32 < f_4^\gamma < 0.33$, and $-0.71 < f_5^\gamma < 0.59$.
- 14 ACHARD 03D study Z-boson pair production in e^+e^- collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 011 results (656 events, expected background of 512 events), they report the following 95%

CL limits: $-0.48 \le f_4^Z \le 0.46$, $-0.36 \le f_5^Z \le 1.03$, $-0.28 \le f_4^{\gamma} \le 0.28$, and $-0.40 \le f_5^{\gamma} \le 0.47$.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised November 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, WWZZ, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the $SU(2)\times U(1)$ gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n , are expressed in terms of the following dimension-6 operators [1,2];

$$L_{6}^{0} = -\frac{e^{2}}{16\Lambda^{2}} a_{0} F^{\mu\nu} F_{\mu\nu} \vec{W}^{\alpha} \cdot \vec{W}_{\alpha}$$

$$L_{6}^{c} = -\frac{e^{2}}{16\Lambda^{2}} a_{c} F^{\mu\alpha} F_{\mu\beta} \vec{W}^{\beta} \cdot \vec{W}_{\alpha}$$

$$L_{6}^{n} = -i \frac{e^{2}}{16\Lambda^{2}} a_{n} \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} F^{\mu\nu}$$

$$\widetilde{L}_{6}^{0} = -\frac{e^{2}}{16\Lambda^{2}} \widetilde{a}_{0} F^{\mu\nu} \widetilde{F}_{\mu\nu} \vec{W}^{\alpha} \cdot \vec{W}_{\alpha}$$

$$\widetilde{L}_{6}^{n} = -i \frac{e^{2}}{16\Lambda^{2}} \widetilde{a}_{n} \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} \widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately (\widetilde{L}_6^0 conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP (\widetilde{L}_6^n violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2 , where V=W or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\mathcal{L}_{AQGC} = -\frac{e^2}{8} \frac{a_0^W}{\Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+a} W_a^{-}$$

$$-\frac{e^2}{16} \frac{a_c^W}{\Lambda^2} F_{\mu\nu} F^{\mu a} (W^{+\nu} W_a^{-} + W^{-\nu} W_a^{+})$$

$$-e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+a} W_a^{-}$$

$$-\frac{e^2 g^2}{2} \frac{\kappa_c^W}{\Lambda^2} F_{\mu\nu} Z^{\mu a} (W^{+\nu} W_a^{-} + W^{-\nu} W_a^{+})$$

$$+\frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}]$$

The energy scale of possible new physics is Λ , and $g = e/\sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{{q'}^2} \frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{{q'}^2} \frac{f_{M,3}}{\Lambda^4}$$

where $g'=e/\cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0}=2f_{M,2}$ and $f_{M,1}=2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total $-f_{S,i}$, $i=1,2,f_{M,i}$, $i=0,\ldots,8$ and $f_{T,i}$, $i=0,\ldots,9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5 , which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

a_0/Λ^2 , a_c/Λ^2

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$

 $-0.029 < a_c^Z/\Lambda^2 < +0.039$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous W/Z quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the W or only to the Z or to both. Thus, results on all other AQGCs are reported together in the W listings.

¹ ABBIENDI 04L OPAL ² HEISTER 04A ALEP ³ ACHARD 02G L3

 2 In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+\,e^-\to\nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be > 5°, $E_\gamma/\sqrt{s}>$ 0.025 (the more energetic photon having energy > 0.2 \sqrt{s}), p $_T_\gamma/\rm E_{beam}>$ 0.05 and $|\cos\theta_\gamma|<$ 0.94. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95%

¹ ABBIENDI 04L select 20 $e^+e^- \rightarrow \nu \overline{\nu} \gamma \gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \rightarrow q \overline{q} \gamma \gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma \gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one-parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023 \ {\rm GeV^{-2}}, -0.029 < a_c^Z/\Lambda^2 < 0.029 \ {\rm GeV^{-2}}, -0.020 < a_0^W/\Lambda^2 < 0.020 \ {\rm GeV^{-2}}, -0.052 < a_c^W/\Lambda^2 < 0.037 \ {\rm GeV^{-2}}.$

CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019 \; {\rm GeV}^{-2}, \, -0.041 < a_c^Z/\Lambda^2 < 0.044 \; {\rm GeV}^{-2}, \, -0.060 < a_0^W/\Lambda^2 < 0.055 \; {\rm GeV}^{-2}, \, -0.099 < a_c^W/\Lambda^2 < 0.093 \; {\rm GeV}^{-2}.$

 3 ACHARD 02G study $e^+\,e^-\to Z\gamma\gamma\to q\overline{q}\gamma\gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy >5 GeV and $|\cos\theta|<0.97$, and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ($\beta<0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q\overline{q}\gamma\gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2=0.00^{+0.02}_{-0.01}$ GeV $^{-2}$ and $a_c/\Lambda^2=0.03^{+0.01}_{-0.02}$ GeV $^{-2}$, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits $-0.02~{\rm GeV}^{-2}< a_0/\Lambda^2<0.03~{\rm GeV}^{-2}$ and $-0.07~{\rm GeV}^{-2}< a_c/\Lambda^2<0.05~{\rm GeV}^{-2}$.
