Neutrino Mixing

NODE=S067 NODE=S067200

With the possible exceptions of "short-baseline anomalies," such as LSND, all neutrino data can be described within the framework of a 3×3 mixing matrix between the mass eigenstates ν_1 , ν_2 , and ν_3 , leading to the flavor eigenstates ν_e , ν_μ , and ν_τ , as described in the review "Neutrino masses, mixing and oscillations."

The Listings are divided in the following sections:

- (A) Neutrino fluxes and event ratios: shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically, ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.
- (B) Neutrino mixing parameters: shows measurements of $\sin^2(\theta_{12})$, $\sin^2(\theta_{23})$, $\sin^2(\theta_{13})$, Δm_{21}^2 , Δm_{32}^2 , and δ_{CP} as extracted from the measured data in the quoted publications in the frame of the three-neutrino mixing scheme. The quoted averages are not the result of a global fit, as in the review "Neutrino masses, mixing, and oscillations," and, as a consequence, might slightly differ from them. In some cases, measurements depend on the mass order (normal when $\Delta m_{32}^2 > 0$ or inverted when $\Delta m_{32}^2 < 0$) or octant of θ_{23} (lower when $\theta_{23} < 45^\circ$ or upper when $\theta_{23} > 45^\circ$).

(C) Other neutrino mixing results:

The LSND anomaly [AGUILAR 01], reported a signal which is consistent with $\overline{\nu}_{\mu} \to \overline{\nu}_{e}$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm_{21}^{2} . This does not appear to be consistent with the interpretation of other neutrino data. It has been interpreted as evidence for a 4th "sterile" neutrino. The following listings include results which might be relevant towards understanding this observation. They include searches for $\nu_{\mu} \to \nu_{e}$, $\overline{\nu}_{\mu} \to \overline{\nu}_{e}$, sterile neutrino oscillations, and others.

(A) Neutrino fluxes and event ratios

Events (observed/expected) from accelerator ν_{μ} experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

$0.71^{+0.08}_{-0.09}$	⁴ ALIU	05	K2K	KEK to Super-K
$0.70^{+0.10}_{-0.11}$	⁵ AHN	03	K2K	KEK to Super-K

 $^{^1}$ The rate of ν_e from μ decay was measured to be 0.68 \pm 0.30 compared to the predicted flux. From K decay 1.10 \pm 0.14 compared to the predicted flux.

Events (observed/expected) from reactor $\overline{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\overline{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels (235 U, 239 Pu, 241 Pu) and on calculations for 238 U.

A recent re-evaluation of the spectral conversion of electron to $\overline{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\overline{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

 1 ALMAZAN 20 use the RHF research reactor at ILL to compare their measured antineutrino event rate to the calculation by HUBER 11. Reported 0.948 \pm 0.008 \pm 0.023 \pm 0.023 measurement with uncertainties from statistics, systematic, and model. Note that this result is obtained for highly enriched ^{235}U reactor fuel while most other reactor experiments utilize a low-enrichment mix of fissile nuclides.

 2 ADEY 19 present a re-analysis of 1230 days of Daya Bay near detector data with reduced systematic uncertainties on the neutron detection efficiency. Note that ADEY 19 report the measured to predicted antineutrino ratio using the reactor model of MUELLER 11 (Huber-Mueller model). The ratio using the older ILL-Vogel model is $1.001\pm0.015\pm0.027$.

 3 AN 16 use 217 days of data (338k events) to determine the neutrino flux ratio relative to the prediction of Mueller-Huber and ILL-Vogel models (see AN 16 for details). The reported flux ratios were corrected for θ_{13} oscillation effect. The flux measurement is consistent with results from previous short-baseline reactor experiments. The measured inverse beta decay yield is $(1.55\pm0.04)\times10^{-18}~{\rm cm}^2/({\rm GW~day})$ or $\sigma_f=(5.92\pm0.14)\times10^{-43}~{\rm cm}^2/{\rm fission}$. About 4σ excess of events was observed in the 4–6 MeV prompt energy region.

 4 DENIZ 10 observe reactor $\overline{\nu}_e \, e$ scattering with recoil kinetic energies 3–8 MeV using CsI(TI) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2\!\theta_W = 0.251 \pm 0.031(\mathrm{stat}) \pm 0.024(\mathrm{sys}).$

⁵ Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

 $^{^2}$ Based on the observation of 112 events when $158.1^{+9.2}_{-8.6}$ were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3 σ . Supersedes ALIU 05.

 $^{^3}$ This ratio is based on the observation of 215 events compared to an expectation of 336 \pm 14 without oscillations. See also ADAMSON 08.

 $^{^4}$ This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of 151^{+12}_{-10} .

 $^{^5\,\}text{This}$ ratio is based on the observation of 56 events with an expectation of $80.1^{+6.2}_{-5.4}$

 $^6\,\text{EGUCHI}$ 03 observe reactor neutrino disappearance at $\sim 180\,\text{km}$ baseline to various Japanese nuclear power reactors.

 7 BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

 8 APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\overline{\nu}_e\, p \to e^+\, n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

 $^9\,\mbox{GREE}\mbox{NWOOD}$ 96 search for neutrino oscillations at 18 m and 24 m from the reactor at $_2\mbox{Savannah}$ River.

10 DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.

 11 KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

Atmospheric neutrinos -

Neutrinos and antineutrinos produced in the atmosphere induce μ -like and e-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e , $R(\mu/e)$, or that of experimental to theoretical $\mu/total$, $R(\mu/total)$ with total $=\mu+e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for μ (N $_{up}(\mu)/N_{down}(\mu)$) or e (N $_{up}(e)/N_{down}(e)$) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

$R(\mu/e) = (Measured Ratio \mu/e) / (Expected Ratio \mu/e)$

 1 ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring e-like events with 0.1 GeV/c < p_e and μ -like events 0.2 GeV/c < p_{μ} , both having a visible energy < 1.33 GeV. These criteria match the definition used by FUKUDA 94.

 2 ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy >1.33 GeV and partially-contained events. All partially-contained events are classified as $\mu\text{-like}.$

 3 SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained e-flavor and $\mu\text{-flavor}$ events having lepton momentum > 0.3 GeV/c.

⁴ FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

 5 DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report $R(\mu/e)=0.99\pm0.13\pm0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

 6 FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e-like events with 0.1 < $p_e < 1.33~{\rm GeV}/c$ and fully-contained μ -like events with 0.2 < $p_{\mu} < 1.5~{\rm GeV}/c$.

⁷ FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy > 1.33 GeV and partially contained μ -like events.

⁸ BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

 1 ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 \pm 13 without oscillations.

AMBROSIO 01 result is based on the upward through-going muon tracks with $E_{\mu}>1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

3 AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

⁴ AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

 5 AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of ± 0.13 . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2\!2\theta{=}1.0$ and $\Delta(m^2)\sim a$ few times 10^{-3} eV². However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation hypothesis.

 6 CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_{\mu}$ induced) fraction is 0.41 \pm 0.03 \pm 0.02, as compared with expected 0.51 \pm 0.05 (syst).

 7 AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define $\rho=$ (measured number of ν_e 's)/(measured number of ν_μ 's). They report $\rho({\rm measured}){=}\rho({\rm expected})=0.96^{+0.28}_{-0.28}.$

⁸ From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$ for maximal mixing, $\nu_\mu \not\to \nu_\mu$ type oscillation.

$R(\mu/\text{total}) = (Measured Ratio <math>\mu/\text{total}) / (Expected Ratio <math>\mu/\text{total})$

Solar neutrinos -

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of $^8{\rm B}.$ Solar neutrino fluxes are composed of all active neutrino species, $\nu_e,~\nu_\mu,~{\rm and}~\nu_\tau.$ In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes

¹ KAFTHER 10 report	ts the reanalysis	result	sofac	complete GALLEX data (GALLEX	NODE—S06		

TECN COMMENT

¹ KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

NODE=S067SNU;LINKAGE=KA

 2 Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

 3 ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense $^{51}\mathrm{Cr}$ (twice by GALLEX and once by SAGE) and $^{37}\mathrm{Ar}$ (by SAGE) result in an average ratio of 0.87 ± 0.05 of the observed to calculated rates.

⁴ ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

NODE=S067SNU;LINKAGE=KE NODE=S067SNU;LINKAGE=AB

NODE=S067SNU;LINKAGE=AL

⁵ Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

 6 HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is 118.4 \pm 17.8 \pm 6.6 SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 71 Ge events were observed. Note that a \sim 15% systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense 51 Cr (twice by GALLEX and once by SAGE) and 37 Ar (by SAGE) result in an average ratio of 0.87 \pm 0.05 of the observed to calculated rates.

NODE=S067SNU;LINKAGE=AT NODE=S067SNU;LINKAGE=HP

 7 CLEVELAND 98 is a detailed report of the 37 Cl experiment at the Homestake Mine. The average solar neutrino-induced 37 Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

NODE=S067SNU;LINKAGE=MC

 ϕ_{ES} (8B)

 $VALUE (10^6 \text{ cm}^{-2} \text{s}^{-1})$

 $^8{\rm B}$ solar-neutrino flux measured via $\nu\,e$ elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu,~\nu_\tau$ due to the cross-section difference, $\sigma(\nu_{\,\mu,\tau}\,e)\sim 0.16\sigma(\nu_e\,e).$ If the $^8{\rm B}$ solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.16 times of $\nu_e.$

³ ALLEGA 24 report	s this result from the	he ν_e	e elastic	scattering rate using the full data	NODE=S067SES;LINKAGE=J

 3 ALLEGA 24 reports this result from the $\nu_e e$ elastic scattering rate using the full data from the SNO+ detector's initial water phase. The events over the reconstructed electron kinetic energy range of 3.5–15 MeV were analyzed. Supersedes ANDERSON 19.

 4 AGOSTINI 20A obtained this result from the $\nu_e\,e$ elastic scattering rate over the period between January 2008 and December 2016. Uses the same data as AGOSTINI 18B, but the analysis technique is significantly improved.

 5 ANDERSON 19 reports this result from the $\nu_e\,e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase. The events over the reconstructed electron kinetic energy range of 5–15 MeV were analyzed. Superseded by ALLEGA 24.

 6 AGOSTINI 18B obtained this result from the $\nu_e\,e$ elastic scattering rate over the period between January 2008 and December 2016.

⁷ ABE 16C reports the combined results of the four phases of the Super-Kamiokande average flux measurements. Here the revised Super-Kamiokande-III result is used. Superseded by ABE 24B.

⁸ ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold is total electron energy of 4.0 MeV. Superseded by ABE 24B.

NODE=S067SES;LINKAGE=J

NODE=S067SES;LINKAGE=G

NODE=S067SES;LINKAGE=F

NODE=S067SES;LINKAGE=D

NODE=S067SES;LINKAGE=A

NODE=S067SES;LINKAGE=B

⁹ ABE 16C revised the Super-Kamiokande-III average flux value reported in ABE 11. Super-Kamiokande-III results are for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron energy range has a total live time of 298 days. Superseded by ABE 24B.

 $^{10}\,\mathrm{ABE}$ 11 recalculated the Super-Kamiokande-II results using $^{8}\,\mathrm{B}$ spectrum of WINTER 06A.

 11 ABE 11 recalculated the Super-Kamiokande-I results using 8 B spectrum of WINTER 06A.

 12 ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the 8 B solar neutrino flux. They utilize $\nu-e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157 \pm 23.6 are assigned to background.

13 BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.

14 AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape.

15 CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.

16 HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

17 AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.

with AHMAD 02 results.

18 AHMAD 02 reports the ⁸B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

 19 AHMAD 01 reports the $^{8}\mathrm{B}$ solar-neutrino flux measured via $\nu\,e$ elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

 $^{20}\,\text{FUKUDA}$ 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $\text{E}_e>9.3\,\text{MeV}$ (first 449 days), $>7.5\,\text{MeV}$ (middle 794 days), and $>7.0\,\text{MeV}$ (last 836 days). These results update the HIRATA 90 result for the average ^8B solar-neutrino flux and HIRATA 91 result for the day-night variation in the ^8B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

ϕ_{CC} (8B)

 $^8{\rm B}$ solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to $\nu_{\rm e}.$

¹ APRILE 24A reports measurements of ⁸B solar neutrinos through coherent scattering with xenon nuclei based on an exposure of 3.51 ton·yr with the XENONnT experiment.

 $^2\,\text{BO}$ 24 reports measurements of ^8B solar neutrinos through coherent scattering with xenon nuclei in the commissioning run and the first science run of the PandaX-4T experiment. Supersedes MA 23A.

³ MA 23A searched for ⁸B solar neutrinos elastically scattered off xenon nuclei in the commissioning phase of the PANDAX-4T experiment with an effective exposure of 0.48 ton yr. This experiment is dedicated to dark matter direct search using a dual-phase xenon TPC with a sensitive volume of 3.7 tons of liquid Xe. Superseded by BO 24.

 4 AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the 8 B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

⁵ AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

⁶ AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape.

AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.

 8 AHMAD 02 reports the first SNO result of the 8 B solar-neutrino flux measured with the neutral-current reaction on deuterium, $\nu_\ell d \to n p \nu_\ell$, above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

1				

 1 ANDERSON 19 reports this result from the measured $\nu_e\,e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase, assuming the neutrino mixing parameters given in PDG 16 and a standard solar model given in BAHCALL 05.

 2 AGOSTINI 18B obtained this result from the measured $\nu_e\,e$ elastic scattering rate over the period between January 2008 and December 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17. Assuming a high-metalicity standard solar model, the electron neutrino survival probability for the $^8{\rm B}$ solar neutrino is calculated to be $0.37\pm0.08.$

³AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the ⁸B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

⁴AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total 8 B neutrino flux and the energy-dependent ν_{ρ} survival probability.

⁵ AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape

⁶ AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.

⁷ AHMAD 02 determined the total flux of active ⁸B solar neutrinos by directly measuring the neutral-current reaction, $\nu_\ell d \to n p \nu_\ell$, which is equally sensitive to ν_e , ν_μ , and ν_τ . The complete description of the SNO Phase I data set is given in AHARMIM 07.

 8 AHMAD 01 deduced the total flux of active 8 B solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande $\nu\,e$ elastic-scattering result (FUKUDA 01).

Total Flux of Active CNO Solar Neutrinos

Total flux of active neutrinos $(\nu_e, \nu_\mu, \nu_\tau)$.

 1 AGOSTINI 20A obtained this result from an upper limit of the $u_{
m e}\,{
m e}$ e elastic scattering rate and NC-mediated inelastic scattering on carbon nuclei with 15.1 MeV deexcitation γ -ray for the hep neutrino. The dataset corresponds to an effective exposure of 0.745 kt yr from November 2009 to October 2017. A FADC DAQ system, optimized for the acquisition of high-energy events was used for data collection. The MSW-LMA oscillation parameters derived by ESTEBAN 17 were assumed.

² AHARMIM 20 uses the entire SNO dataset, corresponding to 2.47 kton yrs of exposure after fiducialization. With the $D_2\mbox{O}$ target, SNO was sensitive to charged current, neutral current, and elastic scattering channels.

 3 AGOSTINI 18B obtained this result from an upper limit of the $u_e e$ elastic scattering rate for the hep neutrino using the dataset corresponding to an exposure of 0.8 kt-yr and assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17.

 $^{^2}$ ABE 24B reports the day-night flux asymmetry of the Super-Kamiokande IV data (2970 live days). Amplitude fit method is used. Supersedes ABE 16C.

 $^{^3\}mathrm{ABE}$ 16C reports the combined day-night flux asymmetry results of the four phases of the Super-Kamiokande measurements. Amplitude fit method is used. See footnote to RENSHAW 14. Superseded by ABE 24B.

 $^{^4}$ ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold for day-night flux asymmetry is recoil electron energy of 4.49 MeV (total electron energy of 5.0 MeV). Amplitude fit method is used. See footnote to RENSHAW 14. Superseded by ABE 24B.

 5 RENSHAW 14 obtains this result by using the "amplitude fit" introduced in SMY 04. The data from the Super-Kamiokande(SK)-I, -II, -III, and 1306 live days of the SK-IV measurements are used. The analysis threshold is recoil-electron kinetic energy of 4.5 MeV for SK-III, and SK-IV except for 250 live days in SK-III (6.0 MeV). The analysis threshold for SK-I and SK-II is the same as in the previous reports. (Note that in the previous SK solar-neutrino results, the analysis threshold is quoted as recoil-electron total energy.) This day-night asymmetry result is consistent with neutrino oscillations for $4\times 10^{-5}~{\rm eV}^2~<\Delta m_{21}^2~<7\times 10^{-5}~{\rm eV}^2$ and large mixing values of θ_{12} at the 68% CI

⁶ CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV except for the first 159 live days (8.0 MeV).

⁷ HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

 8 This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via ν_e elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of ± 0.0004 coming from uncertainty of oscillation parameters.

 9 AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the $^8\mathrm{B}$ shape.

10 AHMAD 02B results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

 11 AHMAD 02B results are derived from the charged-current interactions, neutral-current interactions, and $\nu\,e$ elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

$\phi_{\it ES}$ (⁷Be)

 ^7Be solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu,\,\nu_\tau$ due to the cross-section difference, $\sigma(\nu_{\,\mu,\tau}\,e)\sim 0.2~\sigma(\nu_e\,e).$ If the ^7Be solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.2 times that of $\nu_e.$

 1 GANDO 15 uses 165.4 kton·day exposure of the KamLAND liquid scintillator detector to measure the 862 keV 7 Be solar neutrino flux via $\nu-e$ elastic scattering

 2 BELLINI 11A reports the 7 Be solar neutrino flux measured via $\nu-e$ elastic scattering. The data correspond to 740.7 live days between May 16, 2007 and May 8, 2010, and also correspond to 153.6 ton-year fiducial exposure. BELLINI 11A measured the 862 keV 7 Be solar neutrino flux, which is an 89.6% branch of the 7 Be solar neutrino flux, to be $(2.78\pm0.13)\times10^9~{\rm cm}^{-2}~{\rm s}^{-1}$. Supercedes ARPESELLA 08A.

ϕ_{ES} (pep)

 $p\,e\,p$ solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu,\,\nu_\tau$ due to the cross section difference, $\sigma(\nu_{\mu,\tau}\,\,e)\sim\,$ 0.2 $\sigma(\nu_e\,e).$ If the $p\,e\,p$ solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is $\sim\,$ 0.2 times that of $\nu_e.$

 $^{^1}$ BELLINI 12A reports 1.44 MeV $p\,e\,p$ solar-neutrino flux measured via ν_e elastic scattering. The data were collected between January 13, 2008 and May 9, 2010, corresponding to 20,4009 ton-day fiducial exposure. The listed flux value is calculated from the observed rate of $p\,e\,p$ solar neutrino interactions in Borexino (3.1 \pm 0.6 \pm 0.3 counts/(day·100 ton)) and the corresponding rate expected for no neutrino flavor oscillations (4.47 \pm 0.05 counts/(day·100 ton)), using the SSM prediction for the $p\,e\,p$ solar neutrino flux of (1.441 \pm 0.012) \times 10 8 cm $^{-2}$ s $^{-1}$.

ϕ_{FS} (CNO)

CNO solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_{\mu},\,\nu_{ au}$ due to the cross section difference, $\sigma(\nu_{\mu,\tau}~e)\sim~0.2~\sigma(\nu_e\,e)$. If the CNO solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is $\sim\,$ 0.2 times that of ν_e .

(B) Three-neutrino mixing parameters

DOCUMENT ID TECN COMMENT

NODE=S067260

$\sin^2(\theta_{12})$

If an experiment reports $\sin^2(2\theta_{12})$ we convert the value to $\sin^2(\theta_{12})$.

NODE=S067P12 NODE=S067P12 NODE=S067P12

 $^{^1}$ AGOSTINI 21 derived this result relative to the Standard Solar Model 8B solar neutrino flux, under an assumption of high solar metallicity, of 5.46 (1 \pm 0.12) \times 10 6 cm $^{-2}$ s $^{-1}$ (see VINYOLES 17).

²Superseded by AGOSTINI 21.

 $^{^3}$ BALATA 06 obtained this result from the search for $\overline{\nu}_e$ interactions with Counting Test Facility (the prototype of the Borexino detector).

 1 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0218\pm0.0007$ coming from reactor neutrino experiments, using all solar and KamLAND data. The result includes the full Super-Kamiokande I to IV data. CPT invariance is assumed. Supersedes ABE 16C.

 2 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0218 \pm 0.0007$ coming from reactor neutrino experiments, using all solar data. *CPT* invariance is assumed. Supersedes ABE 16C.

 3 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0218\pm0.0007$ coming from reactor neutrino experiments and a constraint on 8 B(hep) flux based on the SNO neutral current event rate, using full Super-Kamiokande (I+II+III+IV) data. $\it CPT$ invariance is assumed. Supersedes ABE 16C.

 4 SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

 5 ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

 6 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. CPT invariance is assumed. Superseded by ABE 24B.

 7 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data. Superseded by ABE 24B.

⁸ ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data. Superseded by ABE 24B.

 9 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data. Superseded by ABE 24B.

10 FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

 11 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $0.304 {+0.013 \atop -0.012}$ for normal and $0.305 {+0.012 \atop -0.013}$ for inverted mass ordering.

12 AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

 13 AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active 8 B neutrino flux and energy-dependent ν_{e} survival probability parameters, measurements of CI (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)),

- and ^7Be (BELLINI 11A) rates, and ^8B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.
- 14 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.45\times 10^{-3}~\text{eV}^2$, using global solar neutrino data.
- 15 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.45 \times 10 $^{-3}$ eV 2 , using global solar neutrino and KamLAND (GANDO 11) data. CPT invariance is assumed.
- 16 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.
- 17 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.
- 18 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.
- 19 ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.
- ²⁰ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.
- 21 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.4\times 10^{-3}~\text{eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.
- 22 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.4\times 10^{-3}~\text{eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- 23 BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ⁸B flux was left free. CPT invariance is assumed
- 24 BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal 743 24 (2011)) with the exception that the ⁸B flux was left free.
- $^{\rm 25}\,{\rm GANDO}$ 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.
- 26 GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.
- 27 AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALT-MANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- $^{28}\,\text{AHARMIM}\,$ 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- 29 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- 30 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to $2.3\times 10^{-3}~\text{eV}^2$, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- 31 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to $2.3\times 10^{-3}~\text{eV}^2$, using global solar neutrino data.
- 32 ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm^2_{21} and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.
- 33 ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. CPT invariance is assumed. Superseded by GANDO 11. 34 The result given by AHARMIM 08 is $\theta = (34.4^{+1.3}_{-1.2})^{\circ}$. This result is obtained by
- 34 The result given by AHARMIM 08 is $\theta=(34.4^{+1.3}_{-1.2})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- 35 HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK $\nu_{\rm e}$ data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). CPT invariance is assumed.
- 36 HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.

37 HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

 38 The result given by AHARMIM 05A is $\theta=(33.9\pm1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuteron and salt phase data, SK ν_e data, CI and Ga CC data, and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes $\theta=(33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^22\theta=0.86^{+0.05}_{-0.06}$.

 39 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\tan^2\theta=0.45 {+0.09 \atop -0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2\!2~\theta=0.86 {+0.05 \atop -0.07}$

 40 ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The 1σ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2\theta=0.40^{+0.07}_{-0.05}$. The corresponding number quoted in ARAKI 05 is $\tan^2\theta=0.40^{+0.10}_{-0.07}$ (sin^22 $\theta=0.82\pm0.07$), which envelops the 68% CL two-dimensional region.

41 The result given by AHMED 04A is $\theta=(32.5 {+} 1.7)^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\theta=(32.5 {+} 2.4)^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2 \theta = 0.82 \pm 0.06$.

 42 AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2)=6.5\times 10^{-5}~\rm eV^2$, $\tan^2\theta=0.40~(\sin^22~\theta=0.82)$.

 43 The result given by SMY 04 is $\tan^2\theta=0.44\pm0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

⁴⁴SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.

 $^{45}\,\text{SMY}$ 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.

 46 AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2)=5.0\times 10^{-5}~{\rm eV}^2$ and $\tan\theta=0.34~(\sin^22~\theta=0.76).$

⁴⁷ FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$ and $\tan^2\theta = 0.38$ ($\sin^2\theta = 0.80$).

¹ ABE 24B obtain	ed this result by a thre	e-neut	rino osc	cillation analysis, with a constraint of	NODE=S06

 1 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0218 \pm 0.0007$ coming from reactor neutrino experiments, using all solar and Kaml-AND data. The result includes the full Super-Kamiokande I to IV data. CPT invariance is assumed. Supersedes ABE 16C.

 2 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0218 \pm 0.0007$ coming from reactor neutrino experiments and a constraint on $^8\text{B}(\text{hep})$ flux based on the SNO neutral current event rate, using the full Super-Kamiokande I to IV data. Supersedes ABE 16C.

 3 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0218\pm0.0007$ coming from reactor neutrino experiments, using SNO and full Super-Kamiokande I to IV data. Supersedes ABE 16C.

 4 ABE 24B obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0218 \pm 0.0007$ coming from reactor neutrino experiments and a constraint on 8 B(hep) flux based on the SNO neutral current event rate, using the full Super-Kamiokande IV data. Supersedes ABE 16C.

 5 SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

 6 ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

 7 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

 8 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data. Superseded by ABE 24B.

 9 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data. Superseded by ABE 24B.

 10 ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13})=0.0219\pm0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

 11 FORERO 14 performs a global fit to Δm^2_{21} using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

 12 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(7.50^{+0.19}_{-0.17})\times 10^{-5}~\text{eV}^2$ for normal and $(7.50^{+0.18}_{-0.17})\times 10^{-5}~\text{eV}^2$ for inverted mass ordering.

 13 AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

 14 AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active 8 B neutrino flux and energy-dependent ν_{e} survival probability parameters, measurements of CI (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and 7 Be (BELLINI 11A) rates, and 8 B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

 15 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.45 \times 10 $^{-3}$ eV 2 , using global solar neutrino data.

 16 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.45 \times 10^{-3} eV 2 , using global solar neutrino and KamLAND data (GANDO 11). CPT invariance is assumed.

17 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

18 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

 19 GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

20 ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

21 ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

 22 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.4\times 10^{-3}~{\rm eV}^2,$ using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

 23 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.4\times 10^{-3}~\text{eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

²⁴ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ⁸B flux was left free. CPT invariance is assumed.

25 BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal 743 24 (2011)) with the exception that the ⁸B flux was left free.

 $^{26}\,\mbox{GANDO}$ 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

27 GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.

AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALT-MANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

29 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed. NODE=S067DM3;LINKAGE=L

30 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

31 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to 2.3×10^{-3} eV², using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

 32 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to $2.3\times 10^{-3}~\text{eV}^2$, using global solar neutrino data.

 33 ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm^2_{21} and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.

 34 ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

35 AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.

³⁶ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.

³⁷ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.

38 HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

 39 HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the 1σ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta=0.44$ because the fit depends only very weekly on it.

 40 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes $\Delta(m^2)=(8.0^{+0.6}_{-0.4})\times10^{-5}~\text{eV}^2$ as the error enveloping the 68% CL two-dimensional region.

 41 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\Delta(m^2)=(6.5^{+}_{-2.3}^{+4.4})\times 10^{-5}~{\rm eV}^2$ as the error enveloping the 68% CL two-dimensional region.

⁴² ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The 1σ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$, envelops the 68% CL two-dimensional region.

 43 AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\Delta(m^2)=(7.1^{+1.2}_{-0.6})\times 10^{-5}~\text{eV}^2$ as the error enveloping the 68% CL two-dimensional region.

⁴⁴ AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$, $\tan^2\theta = 0.40 \text{ (sin}^2 2 \theta = 0.82)$.

 45 SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

⁴⁶ SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.

 $^{47}\,\text{SMY}$ 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.

 48 AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2)=5.0\times 10^{-5}~{\rm eV}^2$ and $\tan\theta=0.34~(\sin^2\!2~\theta=0.76).$

 49 FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2)=6.9\times 10^{-5}~{\rm eV}^2$ and $\tan^2\theta=0.38$ (sin^22 $\theta=0.80$).

time of the Neutrino2020 conference. 15 AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the ν_{μ} disappearance.

 $^{\mu}$. ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 σ and θ_{23} values in octant II by 1.6 σ . Supersedes $^{12.20}$ ACERO 18. 17 Errors are from normal mass ordering and θ_{13} octant II fits.

NODE=S067P23;LINKAGE=GA

NODE=S067P23;LINKAGE=P

NODE=S067P23;LINKAGE=JA

- ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.
- 19 AARTSEN 18A uses three years (April 2012 May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit result for the inverted mass ordering as $\Delta m_{32}^2 = -2.32 \times 10^{-3} \ \text{eV}^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.
- 20 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm^2_{32} , $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV 2 and $\sin^2\theta_{12} = 0.304 \pm 0.014$. Superseded by WESTER 24.
- ²¹ ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{32}^2 , $\sin^2(\theta_{23})$, and δ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$ eV², $\sin^2(\theta_{12}) = 0.304 \pm 0.014$, and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$. Superseded by WESTER 24.

²² ABE 18G data prefers normal mass ordering is with a posterior probability of 87%. Supersedes ABE 17F.

 23 ACERO 18 performs a joint fit to the data for ν_{μ} disappearance and ν_{e} appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

 24 Errors are from the projections of the 68% contour on 2D plot of Δm^2 versus $\sin^2(\theta_{23})$. ABE 17F supersedes ABE 17A. Superseded by ABE 18G.

 25 Superseded by ACERO 18.

²⁶ ABE 16D reports oscillation results using $\overline{\nu}_{\mu}$ disappearance in an off-axis beam.

 27 ADAMSON 16A obtains $\sin^2(\theta_{23})$ in the 68% C.L. range [0.38, 0.65] ([0.37, 0.64]), with two statistically degenerate best-fit values of 0.44 and 0.59 (0.44 and 0.59) for normal (inverted) mass ordering. Superseded by ADAMSON 17A.

28 AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

 29 ABE 14 results are based on ν_{μ} disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. Superseded by ABE 17A.

 $^{ADC TIA.}$ ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the ν_{μ} disappearance and ν_{e} appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for first θ_{23} octant and inverted mass ordering.

 31 FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

32 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.

33 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

 $^{34}\,\text{The best fit value is}\,\sin^2(\theta_{23}) = 0.514 \pm 0.082.$ Superseded by ABE 14.

 35 ADAMSON 13B obtained this result from ν_{μ} and $\overline{\nu}_{\mu}$ disappearance using ν_{μ} (10.71 \times 10 20 POT) and $\overline{\nu}_{\mu}$ (3.36 \times 10 20 POT) beams, and atmospheric (37.88kton-years) data from MINOS The fit assumed two-flavor neutrino hypothesis and identical ν_{μ} and $\overline{\nu}_{\mu}$ oscillation parameters. Superseded by ADAMSON 14.

³⁶ ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\sin^2(2\theta_{23}) = 0.98$.

 37 ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is $\sin^2(2\theta_{23})=0.95^{+0.10}_{-0.11}\pm0.01.$

 38 ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.

 39 The best fit point is $\Delta m^2=0.0019~\text{eV}^2$ and $\sin^2\!2\theta=0.99.$ The 90% single-parameter confidence interval at the best fit point is $\sin^2\!2\theta\,>\,0.86.$

 40 The data are separated into pure samples of νs and $\overline{\nu} s$, and separate oscillation parameters for νs and $\overline{\nu} s$ are fit to the data. The best fit point is $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$ and $(\Delta \overline{m}^2, \sin^2 2\overline{\theta}) = (0.0016 \text{ eV}^2, 1.00)$. The quoted result is taken from the 90% C.L. contour in the $(\Delta m^2, \sin^2 2\theta)$ plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

- 41 ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.
- 42 ABE 11C obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11C also reported results under a two-neutrino disappearance model with separate mixing parameters between ν and $\overline{\nu}$, and obtained $\sin^2\!2\theta > 0.93$ for ν and $\sin^2\!2\theta > 0.83$ for $\overline{\nu}$ at 90% C.L.

43 ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

- Consistent with the neutrino measurements of ADAMSON 12 at 2.7 4.4 WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.407 0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming $\theta_{13} = 0$ but including the solar oscillation parameters Δm_{21}^2 and $\sin^2\theta_{12}$ in the fit.
- 45 WENDELL 10 obtained this result (sin $^2\theta_{23}=0.43$ –0.61) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 46 WENDELL 10 obtained this result (sin $^2\theta_{23}=0.44-0.63$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 47 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ⁴⁸ Supercedes ALIU 05.
- ⁴⁹ MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- 50 The best fit is for maximal mixing.
- 51 ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017 \ \text{eV}^2$ and $\sin^2(2\theta) = 0.97.$
- 52 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- 53 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- 54 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_{μ} disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- 55 There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- 56 AMBROSIO 03 obtained this result on the basis of the ratio R = N_{low}/N_{high}, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.
- 57 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- ⁵⁸SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the *e*-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta) = 0.97$.
- 59 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- 60 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_{\mu}~>1$ GeV. See the previous footnote.
- 61 FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_{\mu} > 1.6$ GeV, the observed flux is (1.74 \pm 0.07 \pm 0.02) \times 10 $^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. The best fit is $\sin^2(2\theta) = 0.95$.
- 62 FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is (0.39 \pm

 $\rm 0.04\pm0.02)\times10^{-13}~cm^{-2}s^{-1}sr^{-1}.$ This is compared to the expected flux of (0.73 \pm 0.16 (theoretical error)) \times 10 $^{-13}~cm^{-2}s^{-1}sr^{-1}.$ The best fit is to maximal mixing.

63 FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.

 64 FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.

 65 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_{\mu} > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10 {+0.07 \atop -0.06}) \times 10^{-13} \ {\rm cm}^{-2} {\rm s}^{-1} {\rm sr}^{-1}$. This is compared to the expected flux of (2.46 \pm 0.54 (theoretical error)) \times 10 $^{-13}$ cm $^{-2} {\rm s}^{-1} {\rm sr}^{-1}$. The best fit is for maximal mixing.

66 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) = 0.95$.

67 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

Δm_{32}^2

The sign of Δm_{32}^2 is not known at this time. If given, values are shown separately for the normal and inverted mass ordering. Unless otherwise specified, the ranges below correspond to the projection onto the Δm_{32}^2 axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

- $^{
 m 1}$ AIELLO 24 uses atmospheric neutrino data measured between January 2020 and November 2021 with the first six detection units of ORCA, corresponding to 433 kton yrs.
- 2 AIELLO 24 reports $\Delta m^2_{31} = (2.18 ^{+0.25}_{-0.35}) \times 10^{-3}~\text{eV}^2$ for normal mass ordering. We convert to Δm_{32}^2 using PDG 24 value of $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$. 3 AIELLO 24 reports $\Delta m_{31}^2 = -2.25 \times 10^{-3} \text{ to} -1.76 \times 10^{-3} \text{ eV}^2$ at 68% CL for inverted
- mass ordering. We convert to Δm_{32}^2 using PDG 24 value of $\Delta m_{21}^2 = (7.53 \pm 0.18) \times$ $10^{-5}~{\rm eV}^2$. The inverted mass ordering is disfavored with a p-value of 0.25.
- $^4\,\mathrm{AN}$ 24A report results from 1958 days of data taking with the Daya Bay experiment. This analysis makes use of neutron capture on protons and is independent of previous results in AN 23, utilizing neutron capture on Gd.
- ⁵WESTER 24 uses 484.2 kton·years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{32}^2 , $\sin^2(\theta_{23})$, and δ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV², $\sin^2(\theta_{12}) = 0.307 \pm 0.013$, and $\sin^2(\theta_{13}) = 0.0220 \pm 0.0007$. Supersedes ABE 18B.
- $^6\mathrm{ABBASI}$ 23 uses atmospheric neutrino data measured between 2011 and 2019 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Supersedes AARTSEN 18A.
- ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of $1.97 \times 10^{21}~(1.63 \times 10^{21})$ protons on target. Supersedes ABE 20F.
- ⁸ ABE 23F reports $\Delta m_{13}^2 = (2.463 + 0.042) \times 10^{-3} \text{ eV}^2$ for inverted mass ordering. We convert to Δm^2_{32} using PDG 23 value of $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}~\text{eV}^2$.
- ⁹ AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in $5.55 \times 10^6 \ \overline{\nu}_e$ candidate events. Solar oscillation parameters are fixed in the analysis to $\sin^2(\theta_{12})=0.307\pm0.013,$ $\Delta m_{21}^2=(7.53\pm0.18)\times10^{-5}~\text{eV}^2$ from PDG 20. Supersedes ADEY 18A.
- 10 ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 (12.5 \times 10 20 POT) and Feb 6, 2014 to Mar 20, 2020 (13.6 \times 10 20 POT). For normal mass ordering and θ_{23} octant I (lower octant), best fit is 0.00239 eV^2 ; for inverted mass ordering and octant I, best fit is -0.00244 eV^2 . Uncertainties are reported relative to the global minima in normal mass ordering. Supersedes ACERO 19.
- 11 ADAMSON 20A uses the complete dataset from MINOS and MINOS+ experiments. The data were collected using a total exposure of 23.76×10^{20} protons on target and 60.75kton-yr exposure to atmospheric neutrinos. Supersedes ADAMSON 14.
- $^{12}\,\mathrm{BAK}$ 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. We convert the results to Δm_{32}^2 using the PDG 18 values of $\sin^2\!\theta_{12} =$ $0.307^{+0.013}_{-0.012}$ and $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV². Supersedes SEO 18.
- $^{13}\,\mathrm{ABE}$ 25 reports the results of a joint analysis of Super-Kamiokande atmospheric neutrino data and T2K beam neutrino data, using 3244.4 days of atmospheric data and a (anti)neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target.

 14 ABE 25 reports $-\Delta m_{13}^2 = (2.480^{+0.052}_{-0.048}) \times 10^{-3}$ eV² for inverted mass ordering.
- We convert to Δm^2_{32} using PDG 24 value of $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2.$
- $^{15}\hspace{0.05cm}\mathsf{ACERO}$ 24 reanalyzed the dataset first examined in ACERO 22 using an alternative statistical approach based on Bayesian Markov chain Monte Carlo.
- 16 ABE 23D uses the same dataset as ABE 23F. The measurement of Δm^2_{32} is performed independently for u_{μ} and $\overline{
 u}_{\mu}$.
- $^{17}\,\text{ABE}$ 21A results are based on 1.49×10^{21} POT in neutrino mode and 1.64×10^{21} POT in antineutrino mode.
- 18 ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of 1.49×10^{21} (1.64 \times 10²¹) protons on target. Supersedes ABE 18G.
- $^{19}\,\text{ABE}$ 20F reports $\Delta\text{m}^2_{13}\text{=}(2.43\,\pm\,0.07)\times10^{-3}~\text{eV}^2$ for inverted mass ordering. We convert to Δm^2_{32} using PDG 20 value of $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}~\text{eV}^2$
- $^{20}\,\text{ESTEBAN}$ 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.
- 21 AARTSEN 19C uses three years (April 2012 May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the u_{μ} disappearance.
- 22 ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 σ and θ_{23} values in octant II by 1.6 σ . Superseded by ACERO 22.

23 ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

 24 AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit values for the inverted mass ordering as $\Delta m_{32}^2 = -2.32 \times 10^{-3} \ \text{eV}^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

 25 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\!\theta_{23}$, $\sin^2\!\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$ eV² and $\sin^2\!\theta_{12} = 0.304 \pm 0.014$.

 26 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{32}^2 , $\sin^2(\theta_{23})$, and δ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$ eV², $\sin^2(\theta_{12}) = 0.304 \pm 0.014$, and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$. Superseded by WESTER 24.

27 ABE 18G data prefers normal ordering with a posterior probability of 87%. Supersedes ABE 17F.

 28 ABE 18G reports $\Delta m^2_{13} {=} (2.432 \pm 0.070) \times 10^{-3} \text{ eV}^2$ for inverted mass ordering. We convert to Δm^2_{32} using PDG 18 value of $\Delta m^2_{21} {=} (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$.

 29 ACERO 18 performs a joint fit to the data for ν_{μ} disappearance and ν_{e} appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

 30 The error for octant I is taken from the result for octant II.

31 ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with 3.9 \times 10⁶ $\bar{\nu}_e$ candidates. The fit to the data gives $\Delta m_{ee}^2=(2.522^{+0.068}_{-0.070})\times 10^{-3}~\text{eV}^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12})=0.307^{+0.013}_{-0.012},~\Delta m_{21}^2=(7.53\pm0.18)\times 10^{-5}~\text{eV}^2$, from PDG 18. Supersedes AN 17A.

 $^{32}\mathrm{AGAFONOVA}$ 18 assumes maximal θ_{23} mixing.

 33 SEO 18 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm^2_{ee} yields $\Delta m^2_{ee} = (2.62^{+0.21}_{-0.23}^{+0.12}) \times 10^{-3}$ eV 2 . We convert the results to Δm^2_{32} using the PDG 18 values of $\sin^2\theta_{12}$ and Δm^2_{21} . SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18

 34 ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

 $^{35}\,\mathrm{Superseded}$ by ACERO 18.

 36 AN 17A report results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^6 inverse beta-decay events with neutron capture on Gd. The fit to the data gives $\Delta_{ee}^2 = (2.50\pm0.06\pm0.06)\times10^{-3}$ eV. Superseded by ADEY 18A.

 $^{37}\,\mathrm{ABE}$ 16D reports oscillation results using $\overline{\nu}_{\mu}$ disappearance in an off-axis beam.

 38 Superseded by ADAMSON 17A.

 39 CHOI 16 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm^2_{ee} yields $\Delta m^2_{ee} = (2.62^{+0.21}_{-0.23}^{+0.12}) \times 10^{-3}$ eV. We convert the results to Δm^2_{32} using PDG 18 values of $\sin^2(\theta_{12})$ and Δm^2_{21} .

40 AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

 41 AGAFONOVA 15A result is based on 5 $\nu_{\mu} \to ~\nu_{\tau}$ appearance candidates with an expected background of 0.25 \pm 0.05 events. The best fit is for $\Delta m^2_{32}{=}3.3\times 10^{-3}~\text{eV}^2.$

 42 AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of 6.9×10^5 GW $_{th}$ -ton-days. They derive $\Delta m_{ee}^2=(2.42\pm0.11)\times10^{-3}$ eV 2 . Assuming the normal (inverted) ordering, the fitted $\Delta m_{32}^2=(2.37\pm0.11)\times10^{-3}$ $((2.47\pm0.11)\times10^{-3})$ eV 2 . Superseded by AN 17A.

 43 ABE 14 results are based on ν_{μ} disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as $\Delta m_{13}^2 = (2.48 \pm 0.10) \times 10^{-3} \text{ eV}^2$ which we converted to Δm_{32}^2 by adding PDG 14 value of $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$. Superseded by ABE 17c.

 44 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines The analysis combines the ν_{μ} disappearance and ν_{e} appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.

 45 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive $\Delta m_{ee}^2 = (2.59 ^{+}_{-0.20}^{+}) \times 10^{-3} \text{ eV}^2$. Assuming the normal (inverted) ordering, the fitted $\Delta m_{32}^2 = (2.54 ^{+}_{-0.20}^{+0.19}) \times 10^{-3} \ ((2.64 ^{+0.19}_{-0.20}) \times 10^{-3}) \ \text{eV}^2$. Superseded by AN 15

46 FORERO 14 performs a global fit to Δm_{31}^2 using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

 47 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as (2.460 \pm 0.046)×10 $^{-3}$ eV 2 for normal and (2.445 $^{+0.047}_{-0.045})\times10^{-3}$ eV 2 for inverted mass ordering.

⁴⁸ The value for normal mass ordering is actually a measurement of Δm_{31}^2 which differs from Δm_{32}^2 by a much smaller value of Δm_{12}^2 .

49 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

 50 Based on the observation of 58 ν_{μ} events with 205 \pm 17(syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.

 51 ADAMSON 13B obtained this result from ν_{μ} and $\overline{\nu}_{\mu}$ disappearance using ν_{μ} (10.71 \times 10 20 POT) and $\overline{\nu}_{\mu}$ (3.36 \times 10 20 POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical ν_{μ} and $\overline{\nu}_{\mu}$ oscillation parameters.

 52 ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\Delta m_{32}^2=2.65\times 10^{-3}~\text{eV}^2.$

⁵³ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.

54 ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.

 55 The 90% single-parameter confidence interval at the best fit point is $\Delta m^2=0.0019\pm0.0004~eV^2.$

The data are separated into pure samples of νs and $\overline{\nu} s$, and separate oscillation parameters for νs and $\overline{\nu} s$ are fit to the data. The best fit point is $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$ and $(\Delta \overline{m}^2, \sin^2 2\overline{\theta}) = (0.0016 \text{ eV}^2, 1.00)$. The quoted result is taken from the 90% C.L. contour in the $(\Delta m^2, \sin^2 2\theta)$ plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

57 ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19

58 ÅBE 11C obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2 = 1.7 - 3.0 \times 10^{-3} \ {\rm eV}^2$.

 59 ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

bu ADAMSON 11C obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.

 61 WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21}=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

 $^{62}\,\text{ADAMSON}$ 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

⁶³ The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.

64 Supercedes ALIU 05.

 65 MICHAEL 06 best fit is 2.74×10^{-3} eV 2 . See also ADAMSON 08.

66 ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ = eV^2 and $\sin^2 2\theta = 0.97$.

67 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3} \text{ eV}^2$.

 68 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino

interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2=2.3\times 10^{-3}~\text{eV}^2.$

detector. The Dest III is for $\Delta m=2.5\times 10^{-2}$ GeV. ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_{μ} disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2=2.4\times 10^{-3}~{\rm eV}^2$.

 70 There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.

71 AMBROSIO 03 obtained this result on the basis of the ratio R = N $_{low}/N_{high}$, where N $_{low}$ and N $_{high}$ are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \, \mathrm{eV}^2$.

72 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$. 73 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a

⁷³SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3} \text{ eV}^2$.

 74 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.

75 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_{\mu} > 1$ GeV. See the previous footnote.

 76 FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_{\mu}~>1.6$ GeV, the observed flux is $(1.74\pm0.07\pm0.02)\times10^{-13}~{\rm cm}^{-2}{\rm s}^{-1}{\rm sr}^{-1}$.

The best fit is for $\Delta m^2 = 5.9 \times 10^{-3} \text{ eV}^2$.

77 FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2} \text{s}^{-1} \text{sr}^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2} \text{s}^{-1} \text{sr}^{-1}$. The best fit is for $\Delta m^2 = 3.9 \times 10^{-3} \text{ eV}^2$.

 78 FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2=3.1\times 10^{-3}~\text{eV}^2$.

 79 FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$.

 80 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_{\mu} > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10 {+0.07 \atop -0.06}) \times 10^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. This is compared to the expected flux of (2.46 \pm 0.54 (theoretical error)) \times 10 $^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3}$ eV 2 .

⁸¹ HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2 = 13 \times 10^{-3} \text{ eV}^2$.

⁸² FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2 = 16 \times 10^{-3} \text{ eV}^2$.

$\sin^2(\theta_{13})$

At present time direct measurements of $\sin^2(\theta_{13})$ are derived from the reactor $\overline{\nu}_e$ disappearance at distances corresponding to the Δm_{32}^2 value, i.e. L $\sim \,$ 1km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \to \, \nu_e$ experiments.

If an experiment reports $\sin^2(2\theta_{13})$ we convert the value to $\sin^2(\theta_{13})$.

 1 ACERO 24 reanalyzed the NOvA dataset of 13.6×10^{20} POT in neutrino beam node and 12.5×10^{20} POT in antineutrino mode using Bayesian statistical approach. The reported value $\sin^2(2\theta_{13}){=}0.087^{+}_{-}0.020$ marginalized over both mass orderings.

 2 AN 24A performed a combined analysis of data taken by the Daya Bay experiment. 1958 days use neutron capture on protons, 3158 days neutron capture on Gd, as reported in AN 23. Combining these data sets results in 8% error reduction compared to AN 23.

 3 ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of $1.97\times10^{21}~(1.63\times10^{21})$ protons on target.

⁴ DE-KERRET 20 uses 481 days of data from single detector operation and also 384 days of data with both near and far detectors operating. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 16B.

 5 SHIN 20 uses the RENO detector and 1500 live days of data. The near (far) detector observed 567,690 (90,747) $\overline{\nu}_e$ candidate events with a delayed neutron capture on hydrogen. The extracted value of $\sin^2\!\theta_{13}$ is consistent with the previous analysis with neutron capture on Gd in BAK 18.

 6 BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. Supersedes SEO 18.

⁷ AN 24A report results from 1958 days of data taking with the Daya Bay experiment. This analysis makes use of neutron capture on protons and is independent of previous results in AN 23, utilizing neutron capture on Gd.

 8 AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in $5.55\times10^6~\overline{\nu}_e$ candidate events. Solar oscillation parameters are fixed in the analysis to $\sin^2(\theta_{12})=0.307\pm0.013,$ $\Delta m_{21}^2=(7.53\pm0.18)\times10^{-5}~\text{eV}^2$ from PDG 20. Supersedes ADEY 18A.

 9 ABRAHAO 21 uses 865 days of data collected in both near and far detectors with at least one reactor in operation. The analysis is based on a background model independent approach, so called Reactor Rate Modulation, to determine the mixing angle θ_{13} . Adding the background model reduces the uncertainty to 0.0041. Supersedes ABE 16B.

 10 SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

 11 ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

¹² ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\theta_{23}$,

 $\sin^2\!\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$ eV 2 and $\sin^2\!\theta_{12} = 0.304 \pm 0.014$.

 13 ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with 3.9 \times 10 6 $\overline{\nu}_e$ candidates. The fit to the data gives $\Delta m^2_{ee}=$ $(2.522^{+0.068}_{-0.070}) \times 10^{-3} \text{ eV}^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}, \ \Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5} \ \text{eV}^2,$ from PDG 18. Supersedes AN 17A.

 14 AGAFONOVA 18A reports $\sin^2(2\theta_{13})<0.43$ at 90% C.L. The result on the sterile neutrino search in the context of 3+1 model is also reported. A 90% C.L. upper limit on $\sin^2(2\theta_{\mu\,e})=0.021$ for $\Delta m_{41}^2~\geq~0.1~\rm eV^2$ is set.

 $^{15}\,\mathrm{SEO}$ 18 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.

 16 Using T2K data only. For inverted mass ordering, all values of $heta_{13}$ are ruled out at 68%

 $17\,\mathrm{AN}$ 17A reports results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^{6} inverse beta-decay events with neutron capture on Gd. A simultaneous fit to θ_{13} and $\Delta \mathrm{m}^2_{ee}$ is performed. Superseded by ADEY 18A.

18 ABE 16B uses 455.57 live days of data from a detector 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. This analysis uses 7.15 reactor-off days for constraining backgrounds. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 14H and ABE 13C.

19 AN 16A uses data from the eight antineutrino detectors (404 days) and six antineutrino detectors (217 days) runs to determine the mixing parameter $\sin^2(2\theta_{13})$ using the neutron capture on H only. Supersedes AN 14B.

 20 CHOI 16 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. Supersedes AHN 12.

 $^{21}\,\mathrm{AN}$ 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of 6.9 $\times\,10^{5}$ GW $_{th}$ -ton-days. Superseded by AN 17A.

 $^{22}\,\mathrm{ABE}$ 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2 \theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supercedes ABE 12B. 23 ABE 14C result is for ν_e appearance and assumes $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\sin^2(\theta_{23})$

= 0.5, and $\delta=$ 0.

 $^{24}\,\mathrm{ABE}$ 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2 \; \theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Superceded by ABE 16B.

 25 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.

 26 AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of ~ 500 m and ~ 1.6 km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only. $\Delta m_{31}^2 = 2.32 \times 10^{-3} \text{ eV}^2$ is assumed. Superseded by AN 16A.

27 FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, longbaseline accelerator, and atmospheric neutrino data.

 28 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.18 + 0.10) \times 10^{-2} \ \text{eV}^2$ for normal and $(2.19 + 0.12) \times 10^{-2} \ \text{eV}^2$ for inverted mass ordering.

 $^{29}\,\mathrm{ABE}$ 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 16B.

 $^{30}\,\mathrm{ABE}$ 13E assumes maximal θ_{23} mixing and CP phase $\delta=0.$

 31 ADAMSON 13A results obtained from $u_{
m e}$ appearance, assuming $\delta=$ 0, and $\sin^2(2~ heta_{23})$

 32 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $^{2.45} \times 10^{-3}$ eV², using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the NODE=S067P13:LINKAGE=DA

total active $^8{\rm B}$ neutrino flux and energy-dependent ν_e survival probability parameters, measurements of CI (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and $^7{\rm Be}$ (BELLINI 11A) rates, and $^8{\rm B}$ solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is $\sin^2(2~\theta_{13})=(9.1^{+2.9}_{-3.1})\times 10^{-2}$.

 33 AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the $\overline{\nu}_e$ interaction rate ratios. Superseded by AN 14.

34 ABE 12 determines the $\overline{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m_{31}^2 = 2.4 \times 10^{-3} \text{ eV}^2$ is used in the analysis. Superseded by ABE 12B.

 35 ABE 12B determines the neutrino mixing angle θ_{13} using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.

 36 AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle θ_{13} . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \ \text{eV}^2$ was assumed in the analysis. Superseded by CHOI 16.

37 AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$ was assumed in the analysis. Superseded by AN 13.

 38 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to 2.4 \times 10 $^{-3}$ eV 2 , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\!\theta_{13} < 0.059$ (95% CL) or $\sin^2\!2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass ordering and CPT invariance are assumed.

 39 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $^{2.4} \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

neutrino mass ordering is assumed. 40 The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of δ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.

90% region from 0.02 to 0.32. ⁴¹ The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of δ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

⁴² The quoted limit is for $\Delta m_{32}^2=2.32\times 10^{-3}~\text{eV}^2$, $\theta_{23}=\pi/2$, $\delta=0$, and the normal mass ordering. For other values of δ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

 43 The quoted limit is for $\Delta m^2_{32}=2.32\times 10^{-3}~\text{eV}^2,~\theta_{23}=\pi/2,~\delta=0,$ and the inverted mass ordering. For other values of $\delta,$ the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

 44 FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor $\overline{\nu}_e$ fluxess, and using these fluxes, the fitted result becomes 0.10 \pm 0.03.

 45 GANDO 11 report $\sin^2\!\theta_{13}=0.020\pm0.016.$ This result was obtained with three-neutrino fit using the KamLAND+ solar data.

 46 GANDO 11 report $\sin^2\!\theta_{13}=0.032\pm0.037.$ This result was obtained with three-neutrino fit using the KamLAND data only.

⁴⁷ This result corresponds to the limit of <0.12 at 90% CL for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{22} = \pi/2$, and $\delta = 0$. For other values of δ , the 90% CL region spans from 0 to 0.16.

 $\theta_{23}=\pi/2$, and $\delta=0$. For other values of δ , the 90% CL region spans from 0 to 0.16. ⁴⁸ This result corresponds to the limit of <0.20 at 90% CL for $\Delta m_{32}^2=2.43\times 10^{-3}~{\rm eV}^2$, $\theta_{23}=\pi/2$, and $\delta=0$. For other values of δ , the 90% CL region spans from 0 to 0.21.

49 AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALT-MANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

 50 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to $2.3\times 10^{-3}~\text{eV}^2$, using global solar neutrino data and KamLAND data

ABE 25 reports the results of a joint analysis of Super-Kamiokande atmospheric neutrino data and T2K beam neutrino data, using 3244.4 days of atmospheric data and a (anti)neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target.

⁹ ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

 10 ACERO 19 is based on a sample size of 1.33×10^{20} protons on target with combined antineutrino and neutrino data. Superseded by ACERO 22.

 11 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\!\theta_{23}$, $\sin^2\!\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$ eV 2 and $\sin^2\!\theta_{12} = 0.304 \pm 0.014$. Superseded by WESTER 24.

 12 ABE 18B uses 328 kton·years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm^2_{32} , $\sin^2\theta_{23}$, and δ , while the solar parameters and $\sin^2\theta_{23}$ are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, $\sin^2\theta_{12} = 0.304 \pm 0.014$, and $\sin^2\theta_{13} = 0.0219 \pm 0.0012$. Superseded by WESTER 24.

13 ABE 18G confidence intervals are marginalized over both mass orderings. Normal order preferred with a posterior probability of 87%. The 1-sigma result for normal mass ordering used in the average was provided by the experiment via private communications. Supersedes ABE 17F.

14 ACERO 18 performs a joint fit to the data for ν_{μ} disappearance and ν_{e} appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

 15 ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

 $^{16}\,\mathrm{Errors}$ are projections of 68% C.L. curve of δ_{CP} vs. $\sin^2\!\theta_{23}.$

 17 ADAMSON 16 result is based on a data sample with 2.74 \times 10^{20} protons on target. The likelihood-based analysis observed 6 ν_e events with an expected background of 0.99 \pm 0.11 events.

¹⁸ ADAMSON 14 result is based on three-flavor formalism and $\theta_{23} > \pi/4$. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.

19 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.

 20 ADAMSON 13A result is based on ν_e appearance in MINOS and the calculated $\sin^2(2\theta_{23})=0.957, \theta_{23}>\pi/4,$ and normal mass hierarchy. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.

(C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\overline{\nu}_{\mu} \rightarrow \ \overline{\nu}_{e}$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm^2_{21} . This does not appear to be consistent with most of the other neutrino data. The following listings include results from $\nu_{\mu} \rightarrow \ \nu_{e}, \ \overline{\nu}_{\mu} \rightarrow \ \overline{\nu}_{e}$ appearance and $\nu_{\mu}, \ \overline{\nu}_{\mu}, \ \nu_{e},$ and $\overline{\nu}_{e}$ disappearance experiments, and searches for CPT violation.

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ $(\nu_{\mu} \rightarrow \nu_{e})$

NODE=S067D1 NODE=S067D1 1 AGUILAR-AREVALO 21 result is based on a total of 18.75 \times 10^{20} POT in neutrino mode, and 11.27 \times 10^{20} POT in anti-neutrino mode. Best fit at 0.043 eV 2 . The allowed region does not extend to large Δm^2 . The quoted value is the entire allowed region of Δm^2 at 90% C.L. for all values of $\sin^2(2\theta)$. Supersedes AGUILAR-AREVALO 18C.

 2 AGUILAR-AREVALO 18C result is based on $\nu_{\mu} \rightarrow \ \nu_{e}$ appearance of 460.5 \pm 99.0 events; The best fit value is $\Delta m^2 = 0.041 \text{ eV}^2$. Superseded by AGUILAR-AREVALO 21.

 3 AGUILAR-AREVALO 13A result is based on $\nu_{\mu} \rightarrow ~\nu_{e}$ appearance of 162.0 \pm 47.8 events; marginally compatible with two neutrino oscillations. The best fit value is $\Delta m^2=3.14$ eV^2

4 MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of Δm^2 up to 25 eV². The best limit is 0.04 at 7 eV².

SAGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $u_{\mu}
ightarrow \
u_{\rm e}$ oscillations using u_{μ} from π^+ decay in flight by observing beam-on electron events from $\nu_{\rm e}$ C ightarrow e^- X. Present analysis results in 8.1 \pm 12.2 \pm 1.7 excess events in the $60 < E_e < 200$ MeV energy range, corresponding to oscillation probability of $0.10 \pm 0.16 \pm 0.04\%$. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

 6 ATHANASSOPOULOS 98 is a search for the $\nu_{\mu} \to ~\nu_{\rm e}$ oscillations using ν_{μ} from π^+ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e\,{\rm C}$ ightarrow e^- X; the expected background is 21.9 \pm 2.1. Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability $(0.26 \pm 0.10 \pm 0.05)\%$. Although the significance is only 2.3σ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\overline{\nu}_{\mu} \to \, \overline{\nu}_{\it e}$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98B.

 $^{7}\mathsf{LOVERRE}$ 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 1 AGUILAR-AREVALO 21 result is based on a total of 18.75×10^{20} POT in neutrino mode, and 11.27×10^{20} POT in anti-neutrino mode. The best fit value is $\sin^2(2\theta) = 0.807$. The allowed region does not extend to large Δm^2 . The quoted value is the entire allowed region of $\sin^2(2\theta)$ at 90% C.L. for all values of Δm^2 . Supersedes AGUILAR-

AREVALO 18C. 2 AGUILAR-AREVALO 18C result is based on $\nu_{\mu} \to ~\nu_{\rm e}$ appearance of 460.5 \pm 99.0 events; The best fit value is $\sin^2(2\theta) = 0.92$. The quoted limit for the two-neutrino mixing angle θ is valid above $\Delta m^2 = 0.59 \text{ eV}^2$. Superseded by AGUILAR-AREVALO 21.

 3 AGUILAR-AREVALO 13A result is based on $\nu_{\mu} \rightarrow ~\nu_{\rm e}$ appearance of 162.0 \pm 47.8 events; marginally compatible with two neutrino oscillations. The best fit value is $\sin^2(2\theta) =$

 4 ANTONELLO 13 use the ICARUS T600 detector at LNGS and \sim 20 GeV beam of u_{μ} from CERN 730 km away to search for an excess of ν_e events. Two events are found with 3.7 \pm 0.6 expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13A.

 5 Based on four events with a background of 6.4 \pm 0.9 from conventional sources with an average energy of 20 GeV and 730 km from the source of ν_μ

 6 MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data. 7 The limit is $\sin^2\!2\theta~<~0.9\times10^{-3}$ at $\Delta m^2=2~\rm eV^2$. That value of Δm^2 corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

OCCUR=2

NODE=S067S1;LINKAGE=F

NODE=S067S1;LINKAGE=D

NODE=S067S1;LINKAGE=A

NODE=S067S1:LINKAGE=C

NODE=S067S1;LINKAGE=B

NODE=S067S1;LINKAGE=MA NODE=S067S1;LINKAGE=AI

 8 The limit becomes $\sin^2\!2\theta < 0.15$ at $\Delta m^2 = 2.8\times 10^{-3}$ eV², the bets-fit value of the ν_{tt} disappearance analysis in K2K.

 9 AGUILAR 01 is the final analysis of the LSND full data set of the search for the $\nu_{\mu} \to \nu_e$ oscillations. See footnote in preceding table for further details.

 10 ATHANASSOPOULOS 98 report (0.26 \pm 0.10 \pm 0.05)% for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2 . See also ATHANASSOPOULOS 98B.

11 LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 12 VILAIN 94C limit derived by combining the ν_{μ} and $\overline{\nu}_{\mu}$ data assuming CP conservation.

¹ Based on $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e}$ appearance of 78.4 \pm 28.5 events. The best fit values are $\Delta m^2 = 0.043 \text{ eV}^2$ and $\sin^2 2\theta = 0.88$.

²CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

 3 This value is for a two neutrino oscillation analysis for excess antineutrino events with E $_{\nu} >$ 475 MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.

⁴ This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_{\nu} > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV².

 5 ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\overline{\nu}_e$, detected by the inverse β -decay reaction on protons and 12 C. 15 candidate events are observed, and 15.8 \pm 0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

⁶ AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly for π^+ decay at rest. $\overline{\nu}_e$ are detected through $\overline{\nu}_e p \to e^+ n$ (20< $E_{e^+} <$ 60 MeV) in delayed coincidence with $np \to d\gamma$. Authors observe 87.9 \pm 22.4 \pm 6.0 total excess events. The observation is attributed to $\overline{\nu}_{\mu} \to \overline{\nu}_e$ oscillations with the oscillation probability of 0.264 \pm 0.067 \pm 0.045%, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from 0.2–2.0 eV². Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

7 ATHANASSOPOULOS 96 is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\overline{\nu}_e$ could come from either $\overline{\nu}_\mu \to \overline{\nu}_e$ or $\nu_e \to \overline{\nu}_e$; our entry assumes the first interpretation. They are detected through $\overline{\nu}_e \, p \to e^+ \, n$ (20 MeV $<\!E_{e^+} <\!60$ MeV) in delayed coincidence with $np \to d\gamma$. Authors observe 51 \pm 20 \pm 8 total excess events over an estimated background 12.5 \pm 2.9. ATHANASSOPOULOS 96B is a shorter version of this paper.

⁸ ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18}\pm0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96

ATHANASSOPOULOS 96. 9 HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e}$ and obtains only upper limits.

 10 FREEDMAN 93 is a search at LAMPF for $\overline{\nu}_e$ generated from any of the three neutrino types $\nu_\mu,\,\overline{\nu}_\mu,$ and ν_e which come from the beam stop. The $\overline{\nu}_e$'s would be detected by the reaction $\overline{\nu}_e\,p\to\,e^+\,n.$ FREEDMAN 93 replaces DURKIN 88.

 1 AN 24 use the full data set of the Daya Bay reactor experiment, corresponding to 3158 days of detector operation, to place a limit on $\overline{\nu}_e \to \overline{\nu}_s$ oscillations. The result is in terms of $\sin^2(2\theta_{14})$ for $0.01~\text{eV}^2 < \Delta m_{41}^2 < 0.1~\text{eV}^2$. A 3+1 mixing model is assumed.

 2 AUGIER 24 use of 1.47 kg·yr of 100 Mo exposure of the CUPID-Mo scintillating cryogenic calorimeter, operated at the Laboratoire Souterrain de Modane, to place a range of limits on the admixture of sterile neutrinos. Two different $2\nu\beta\beta$ spectral analysis approaches are used. $\sin^2(\theta_{14})$ is given for sterile neutrino masses ranging from 0.5 to 1.5 MeV. The limit above is for 0.5 MeV mass.

 3 AKER 23 assume a 3+1 neutrino mixing model, use low-rate commissioning data of the KATRIN tritium β decay experiment to place a limit on $\sin^2(\theta_{14})$ for a admixture sterile neutrino mass $\rm m_4$ of $\sim~300$ eV.

 4 ALMAZAN 23 use inverse beta decay data collected by the STEREO experiment, placed 9 to 11 m from the ILL research reactor, to search for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations. The ILL research reactor uses highly enriched 235 U fuel. No indication of the oscillation to sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m_{41}^2 \sim 1 \text{ eV}^2$ where the exclusion is maximal. Supersedes ALMAZAN 18.

 5 AKER 22A uses the first two science runs of the KATRIN tritium β decay neutrino mass experiment to search for an admixture of sterile neutrinos. No evidence is found for a spectral anomaly, indicating such admixture. The resulting limit is on $\sin^2(2\theta_{14})$ for sterile neutrino masses $m_4 <$ 40 eV. It is most restrictive at $\Delta m_{41}^2 \sim 400$ eV 2 . A $_3+1$ model is assumed.

 6 ATIF 22 report results from the combined analysis of the RENO (419 m) and NEOS (24 m) experiments data, collected at the Hanbit Nuclear Power Plant. Results, in terms of $\sin^2(2\theta_{14})$, constrain for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations. The authors report both excluded and allowed parameter combinations. The exclusion result reported here is based on the Feldman-Cousins method and for $\Delta m_{41}^2 \simeq 0.55 \text{ eV}^2$. Part of the allowed area is excluded by the STEREO and PROSPECT experiments.

⁷ BARINOV 22A report an event deficit observed using the segmented Baksan Ga neutrino detector, exposed to a 3.4 MCi 51 Cr source. Equal suppression factors are observed for the inner and outer segments. The deficit is interpreted as evidence for oscillations to sterile neutrinos. The result is in terms of $\sin^2(2\theta_{14})$, for a best fit of $\Delta m_{41}^2 = 3.3^{+\infty}_{-2.3}$

 $\mbox{eV}^2.$ Some, but not all, of the allowed neutrino parameter space conflicts with other experiments.

 8 ANDRIAMIRADO 21 reports a search for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations at the HFIR research reactor, at baselines from 6.7 to 9.2 m. The reactor has a 235 U core. 4 tons of 6 Li-doped liquid scintillator are used in a segmented detector. Oscillations into sterile neutrinos are disfavored. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m_{41}^2 \sim 2 \text{ eV}^2$ where the sensitivity is maximal.

 9 SEREBROV 21 searches for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations with a moveable detector with baseline 6–12 m from the SM-3 research reactor with highly enriched 235 U fuel. Analyzing the L/E dependence a χ^2 minimum is found at $\Delta m_{41}^2 = 7.3 \pm 0.13 \pm 1.16 \ eV^2$ and $\sin^2(2\theta_{14}) = 0.36 \pm 0.12$. The quoted limit of 0.005 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m_{41}^2 \sim 2 \ eV^2$. This is the result from 720 days of reactor ON and 860 days of reactor OFF measurements. The significance of the χ^2 minimum is 2.9 σ . Supersedes SEREBROV 20, SEREBROV 19 and SEREBROV 18A.

 10 SKROBOVA 20 searches for $\overline{\nu}_e - \overline{\nu}_s$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW $_{th}$ power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. No evidence for sterile neutrinos is found. The quoted limit 0.008, the smallest excluded $\sin^2(2\theta_{14})$, corresponds to $\Delta m_{41}^2 \sim 1.0 \ \text{eV}^2$. Supersedes ALEKSEEV 18.

 11 ALEKSEEV 18 searches for $\overline{\nu}_e \rightarrow \overline{\nu}_{\mathcal{S}}$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW $_{th}$ power reactor. The DANSS detector is highly segmented

and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. The best fit point is at $\Delta m_{41}^2=1.4~\text{eV}^2$ and $\sin^2(2\theta_{14})=0.05$ with $\Delta\chi^2=13.1$ (statistical errors only) compared to the fit with 3 active neutrinos only. The quoted limit of 0.01 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m_{41}^2~\sim~1.0~\text{eV}^2$. Superseded by SKROBOVA 20.

 12 ALMAZAN 18 searches for the $\overline{\nu}_e \to \overline{\nu}_s$ oscillations with baseline from 9.4 to 11.1 m from the ILL research reactor with highly enriched 235 U fuel. The STEREO detector consists of six separated cells with Gd loaded scintillator, with 15 m water equivalent overburden. The detected rate is $396.3 \pm 4.7~\overline{\nu}_e/\text{day}$ with signal to background ratio of about 0.9. The reported results corresponds to 66 days of reactor-on. The analysis uses the relative rates normalized to the cell number 1. No indication of the oscillation to the sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m_{41}^2 \sim 3.5~\text{eV}^2$ where the exclusion is maximal. Superseded by ALMAZAN 23.

 13 ASHENFELTER 18 searches for the $\overline{\nu}_e \to \overline{\nu}_s$ oscillations at baseline from 6.7 to 9.2 m from the 85 MW research reactor with pure 235 U core. The segmented 4 ton 6 Li-doped liquid scintillator is operated with about 1 m water equivalent overburden and recorded 25461 ± 283 IBD events. No indication of oscillations into sterile neutrinos was observed. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m_{41}^2 \sim 2 \text{ eV}^2$ where the sensitivity is maximal.

 14 AARTSEN 17B uses three years of upward-going atmospheric neutrino data in the energy range of 10-60 GeV to constrain their disappearance into light sterile neutrinos. The reported limit $\sin^2\!\theta_{24}~<0.11$ at 90% C.L. is for $\Delta m_{41}^2=1.0~\text{eV}^2$. We convert the result to $\sin^2\!2\theta_{24}$ for the listing. AARTSEN 17B also reports $\cos^2\!\theta_{24}\cdot\sin^2\!\theta_{34}~<0.15$ at 90% C.L. for $\Delta m_{41}^2=1.0~\text{eV}^2$.

 15 ABDURASHITOV 17 use the Troitsk nu-mass experiment to search for sterile neutrinos with mass 0.1 - 2 keV. We convert the reported limit from U_{e4}^2 $<\!0.002$ to $\sin^2\!2\theta_{14}$ $<\!0.008$ assume $U_{e4}\sim \sin\theta_{14}.$ The stated limit corresponds to the smallest $U_{e4}^2.$ The exclusion curve begins at U_{e4}^2 of 0.02 for $\mathrm{m_4}=0.1$ keV.

 16 KO 17 reports on short baseline reactor oscillation search $(\overline{\nu}_e \rightarrow \overline{\nu}_s)$, motivated be the so-called "reactor antineutrino anomaly". The experiment is conducted at 23.7 m from the core of unit 5 of the Hanbit Nuclear Power Complex in Korea. the reported limited on $\sin^2(2\theta_{41})$ for sterile neutrinos was determined using the reactor antineutrino spectrum determined by the Daya Bay experiment for Δm_{14}^2 around 0.55 eV 2 where the sensitivity is maximal. A fraction of the parameter space derived from the "reactor antineutrino anomaly" is excluded by this work. Compared to reactor models an event excess is observed at about 5 MeV, in agreement with other experiments.

 17 AARTSEN 16 use one year of upward-going atmospheric muon neutrino data in the energy range of 320 GeV to 20 TeV to constrain their disappearance into light sterile neutrinos. Sterile neutrinos are expected to produce distinctive zenith distribution for these energies for 0.01 $\leq \Delta \text{m}^2 \leq$ 10 eV². The stated limit is for $\sin^2\!2\theta_{24}$ at Δm^2 around 0.3 eV².

around 0.3 eV . 18 ADAMSON 16B combine the results of AN 16B, ADAMSON 16C, and Bugey-3 reactor experiments to constrain ν_{μ} to ν_{e} mixing through oscillations into light sterile neutrinos. The stated limit for $\sin^{2}\!2\theta_{\mu\,e}$ is at $\left|\Delta m_{41}^{2}\right|=1.2$ eV².

 19 ADAMSON 16C use the NuMI beam and exposure of 10.56×10^{20} protons on target to search for the oscillation of ν_{μ} dominated beam into light sterile neutrinos with detectors at 1.04 and 735 km. The reported limit $\sin^2(\theta_{24}) < 0.022$ at 95% C.L. is for $\left|\Delta m_{41}^2\right| = 0.5 \text{ eV}^2$. We convert the result to $\sin^2(2\theta_{24})$ for the listing.

 20 AN 16B utilize 621 days of data to place limits on the $\overline{\nu}_e$ disappearance into a light sterile neutrino. The stated limit corresponds to the smallest $\sin^2(2\theta_{14})$ at $|\Delta m_{41}^2|\sim 3\times 10^{-2}~\text{eV}^2$ (obtained from Figure 3 in AN 16B). The exclusion curve begins at $|\Delta m_{41}^2|\sim 1.5\times 10^{-4}~\text{eV}^2$ and extends to $\sim 0.25~\text{eV}^2$. The analysis assumes $\sin^2(2\theta_{12})=0.846\pm 0.021,$ $\Delta m_{21}^2=(7.53\pm 0.18)\times 10^{-5}~\text{eV}^2,$ and $|\Delta m_{32}^2|=(2.44\pm 0.06)\times 10^{-3}~\text{eV}^2$

eV². 21 AMBROSIO 01 tested the pure 2-flavor $\nu_{\mu} \rightarrow \nu_{s}$ hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and Δm^2 around 0.0024 eV², the $\nu_{\mu} \rightarrow \nu_{s}$ oscillation is disfavored with 99% confidence level with respect to the $\nu_{\mu} \rightarrow \nu_{\tau}$ hypothesis.

 22 FUKUDA 00 tested the pure 2-flavor $\nu_{\mu} \rightarrow \nu_{s}$ hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the $\Delta \rm m^2$ and $\rm sin^2 2\theta$ region preferred by the Super-Kamiokande data, the $\nu_{\mu} \rightarrow \nu_{s}$ hypothesis isrejected at the 99% confidence level, while the $\nu_{\mu} \rightarrow \nu_{\tau}$ hypothesis consistently fits all of the data sample.
