

## 14. STRUCTURE FUNCTIONS

Written Summer 2001 by B. Foster (University of Bristol), A.D. Martin (University of Durham), M.G. Vinciter (University of Alberta).

### 14.1. Deep inelastic scattering

High energy lepton-nucleon scattering (deep inelastic scattering) plays a key role in determining the partonic structure of the proton. The process  $\ell N \rightarrow \ell' X$  is illustrated in Fig. 14.1. The filled circle in this figure represents the internal structure of the proton which can be expressed in terms of structure functions.

**Figure 14.1:** Kinematic quantities for the description of deep inelastic scattering. The quantities  $k$  and  $k'$  are the four-momenta of the incoming and outgoing leptons,  $P$  is the four-momentum of a nucleon with mass  $M$ , and  $W$  is the mass of the recoiling system  $X$ . The exchanged particle is a  $\gamma$ ,  $W^\pm$ , or  $Z$ ; it transfers four-momentum  $q = k - k'$  to the nucleon.

Invariant quantities:

$\nu = \frac{q \cdot P}{M} = E - E'$  is the lepton's energy loss in the nucleon rest frame (in earlier literature sometimes  $\nu = q \cdot P$ ). Here,  $E$  and  $E'$  are the initial and final lepton energies in the nucleon rest frame.

$Q^2 = -q^2 = 2(EE' - \vec{k} \cdot \vec{k}') - m_\ell^2 - m_{\ell'}^2$ , where  $m_\ell(m_{\ell'})$  is the initial (final) lepton mass. If  $EE' \sin^2(\theta/2) \gg m_\ell^2, m_{\ell'}^2$ , then

$\approx 4EE' \sin^2(\theta/2)$ , where  $\theta$  is the lepton's scattering angle in the nucleon rest frame with respect to the lepton beam direction.

$x = \frac{Q^2}{2M\nu}$  where, in the parton model,  $x$  is the fraction of the nucleon's momentum carried by the struck quark.

$y = \frac{q \cdot P}{k \cdot P} = \frac{\nu}{E}$  is the fraction of the lepton's energy lost in the nucleon rest frame.

$W^2 = (P + q)^2 = M^2 + 2M\nu - Q^2$  is the mass squared of the system  $X$  recoiling against the scattered lepton.

$s = (k + P)^2 = \frac{Q^2}{xy} + M^2 + m_\ell^2$  is the center-of-mass energy squared of the lepton-nucleon system.

## 2 14. Structure functions

The process in Fig. 14.1 is called deep ( $Q^2 \gg M^2$ ) inelastic ( $W^2 \gg M^2$ ) scattering (DIS). In what follows, the masses of the initial and scattered leptons,  $m_\ell$  and  $m'_\ell$ , are neglected.

### 14.1.1. DIS cross sections:

$$\frac{d^2\sigma}{dx dy} = x(s - M^2) \frac{d^2\sigma}{dx dQ^2} = \frac{2\pi M\nu}{E'} \frac{d^2\sigma}{d\Omega_{\text{Nrest}} dE'} . \quad (14.1)$$

In lowest order perturbation theory the cross section for the scattering of polarised leptons on polarised nucleons can be expressed in terms of the products of leptonic and hadronic tensors associated with the coupling of the exchanged bosons at the upper and lower vertices in Fig. 14.1 (see Refs. [1,2,3,4])

$$\frac{d^2\sigma}{dxdy} = \frac{2\pi y\alpha^2}{Q^4} \sum_j \eta_j L_j^{\mu\nu} W_{\mu\nu}^j . \quad (14.2)$$

For neutral-current processes the summation is over  $j = \gamma, Z$  and  $\gamma Z$  representing photon and  $Z$  exchange and the interference between them, whereas for charged-current interactions there is only  $W$  exchange,  $j = W$ . (For transverse nucleon polarization there is a dependence on the azimuthal angle of the scattered lepton.)  $L_{\mu\nu}$  is the lepton tensor associated with the coupling of the exchange boson to the leptons. For incoming leptons of charge  $e = \pm 1$  and helicity  $\lambda = \pm 1$

$$\begin{aligned} L_{\mu\nu}^\gamma &= 2 \left( k_\mu k'_\nu + k'_\mu k_\nu - k \cdot k' g_{\mu\nu} - i\lambda \varepsilon_{\mu\nu\alpha\beta} k^\alpha k'^\beta \right) \\ L_{\mu\nu}^{\gamma Z} &= (g_V^e + e\lambda g_A^e) L_{\mu\nu}^\gamma \\ L_{\mu\nu}^Z &= (g_V^e + e\lambda g_A^e)^2 L_{\mu\nu}^\gamma \\ L_{\mu\nu}^W &= (1 + e\lambda)^2 L_{\mu\nu}^\gamma \end{aligned} \quad (14.3)$$

where

$$g_V^e = -\frac{1}{2} - 2e \sin^2 \theta_W, \quad g_A^e = -\frac{1}{2} .$$

Although here the helicity formalism is adopted, an alternative approach is to express the tensors in Eq. (14.3) in terms of the polarization of the lepton.

The factors  $\eta_j$  in Eq. (14.2) denote the ratios of the corresponding propagators and couplings to the photon propagator and coupling squared

$$\begin{aligned} \eta_\gamma &= 1 \\ \eta_{\gamma Z} &= \left( \frac{G_F M_Z^2}{2\sqrt{2}\pi\alpha} \right) \left( \frac{Q^2}{Q^2 + M_Z^2} \right) \\ \eta_Z &= \eta_{\gamma Z}^2 \\ \eta_W &= \frac{1}{2} \left( \frac{G_F M_W^2}{4\pi\alpha} \frac{Q^2}{Q^2 + M_W^2} \right)^2 . \end{aligned} \quad (14.4)$$

The hadronic tensor, which describes the interaction of the appropriate electroweak currents with the target nucleon, is given by

$$W_{\mu\nu} = \frac{1}{4\pi} \int d^4z e^{iq \cdot z} \langle P, S | [J_\mu^\dagger(z), J_\nu(0)] | P, S \rangle, \quad (14.5)$$

where  $S$  denotes the nucleon-spin 4-vector, with  $S^2 = -M^2$  and  $S \cdot P = 0$ .

## 14.2. Structure functions of the proton

The structure functions are defined in terms of the hadronic tensor (see Refs. [1,2,3])

$$\begin{aligned} W_{\mu\nu} = & \left( -g_{\mu\nu} + \frac{q_\mu q_\nu}{q^2} \right) F_1(x, Q^2) + \frac{\hat{P}_\mu \hat{P}_\nu}{P \cdot q} F_2(x, Q^2) \\ & - i\varepsilon_{\mu\nu\alpha\beta} \frac{q^\alpha P^\beta}{2P \cdot q} F_3(x, Q^2) \\ & + i\varepsilon_{\mu\nu\alpha\beta} \frac{q^\alpha}{P \cdot q} \left[ S^\beta g_1(x, Q^2) + \left( S^\beta - \frac{S \cdot q}{P \cdot q} P^\beta \right) g_2(x, Q^2) \right] \\ & + \frac{1}{P \cdot q} \left[ \frac{1}{2} \left( \hat{P}_\mu \hat{S}_\nu + \hat{S}_\mu \hat{P}_\nu \right) - \frac{S \cdot q}{P \cdot q} \hat{P}_\mu \hat{P}_\nu \right] g_3(x, Q^2) \\ & + \frac{S \cdot q}{P \cdot q} \left[ \frac{\hat{P}_\mu \hat{P}_\nu}{P \cdot q} g_4(x, Q^2) + \left( -g_{\mu\nu} + \frac{q_\mu q_\nu}{q^2} \right) g_5(x, Q^2) \right] \end{aligned} \quad (14.6)$$

where

$$\hat{P}_\mu = P_\mu - \frac{P \cdot q}{q^2} q_\mu, \quad \hat{S}_\mu = S_\mu - \frac{S \cdot q}{q^2} q_\mu. \quad (14.7)$$

In Ref. 2 the definition of  $W_{\mu\nu}$  with  $\mu \leftrightarrow \nu$  is adopted which changes the sign of the  $\varepsilon_{\mu\nu\alpha\beta}$  terms in Eq. (14.6), although the formulae given here below are unchanged. Ref. 1 tabulates the relation between the structure functions defined in Eq. (14.6) and other choices available in the literature.

The cross sections for neutral and charged-current deep inelastic scattering on unpolarized nucleons can be written in terms of the structure functions in the generic form

$$\begin{aligned} \frac{d^2\sigma^i}{dxdy} = & \frac{4\pi\alpha^2}{xyQ^2} \eta^i \left\{ \left( 1 - y - \frac{x^2 y^2 M^2}{Q^2} \right) F_2^i \right. \\ & \left. + y^2 x F_1^i \mp \left( y - \frac{y^2}{2} \right) x F_3^i \right\}, \end{aligned} \quad (14.8)$$

where  $i = \text{NC}$ ,  $\text{CC}$  corresponds to neutral-current ( $eN \rightarrow eX$ ) or charged-current ( $eN \rightarrow \nu X$  or  $\nu N \rightarrow eX$ ) processes, respectively. In the last term the  $-$  sign is taken for

## 4 14. Structure functions

an incoming  $e^+$  or  $\bar{\nu}$  and the  $+$  sign for an incoming  $e^-$  or  $\nu$ . The factor  $\eta^{\text{NC}} = 1$  for unpolarized  $e^\pm$  beams, whereas\*

$$\eta^{\text{CC}} = (1 \pm \lambda)^2 \eta_W \quad (14.9)$$

with  $\pm$  for  $\ell^\pm$  and where  $\lambda$  is the helicity of the incoming lepton.  $\eta_W$  is defined in Eq. (14.4). The CC structure functions, which derive exclusively from  $W$  exchange, are

$$F_1^{\text{CC}} = F_1^W, \quad F_2^{\text{CC}} = F_2^W, \quad xF_3^{\text{CC}} = xF_3^W. \quad (14.10)$$

The NC structure functions  $F_2^\gamma, F_2^{\gamma Z}, F_2^Z$  are, for  $e^\pm N \rightarrow e^\pm X$ , given by Ref. 5,

$$F_2^{\text{NC}} = F_2^\gamma - (g_V^e \pm \lambda g_A^e) \eta_{\gamma Z} F_2^{\gamma Z} + (g_V^e{}^2 + g_A^e{}^2 \pm 2\lambda g_V^e g_A^e) \eta_Z F_2^Z \quad (14.11)$$

and similarly for  $F_1^{\text{NC}}$ , whereas

$$xF_3^{\text{NC}} = -(g_A^e \pm \lambda g_V^e) \eta_{\gamma Z} xF_3^{\gamma Z} + [2g_V^e g_A^e \pm \lambda(g_V^e{}^2 + g_A^e{}^2)] \eta_Z xF_3^Z. \quad (14.12)$$

The polarized cross-section difference

$$\Delta\sigma = \sigma(\lambda_n = -1, \lambda_\ell) - \sigma(\lambda_n = 1, \lambda_\ell), \quad (14.13)$$

where  $\lambda_\ell, \lambda_n$  are the helicities ( $\pm 1$ ) of the incoming lepton and nucleon, respectively, may be expressed in terms of the five structure functions  $g_{1,\dots,5}(x, Q^2)$  of Eq. (14.6). Thus,

$$\begin{aligned} \frac{d^2 \Delta\sigma^i}{dx dy} &= \frac{8\pi\alpha^2}{xyQ^2} \eta^i \left\{ -\lambda_\ell y \left( 2 - y - 2x^2 y^2 \frac{M^2}{Q^2} \right) xg_1^i + \lambda_\ell 4x^3 y^2 \frac{M^2}{Q^2} g_2^i \right. \\ &+ 2x^2 y \frac{M^2}{Q^2} \left( 1 - y - x^2 y^2 \frac{M^2}{Q^2} \right) g_3^i \\ &\left. - \left( 1 + 2x^2 y \frac{M^2}{Q^2} \right) \left[ \left( 1 - y - x^2 y^2 \frac{M^2}{Q^2} \right) g_4^i + xy^2 g_5^i \right] \right\} \quad (14.14) \end{aligned}$$

with  $i = \text{NC}$  or  $\text{CC}$  as before. The Eq. (14.13) corresponds to the difference of antiparallel minus parallel spins of the incoming particles for  $e^-$  or  $\nu$  initiated reactions, but parallel minus antiparallel for  $e^+$  or  $\bar{\nu}$  initiated processes. For longitudinal nucleon polarization, the contributions of  $g_2$  and  $g_3$  are suppressed by powers of  $M^2/Q^2$ . These structure functions give an unsuppressed contribution to the cross section for transverse polarization Ref. 1, but in this case the cross-section difference vanishes as  $M/Q \rightarrow 0$ .

Because the same tensor structure occurs in the spin-dependent and spin-independent parts of the hadronic tensor of Eq. (14.6) in the  $M^2/Q^2 \rightarrow 0$  limit, the differential

cross-section difference of Eq. (14.14) may be obtained from the differential cross section Eq. (14.8) by replacing

$$F_1 \rightarrow -g_5, \quad F_2 \rightarrow -g_4, \quad F_3 \rightarrow 2g_1, \quad (14.15)$$

and multiplying by two, since the total cross section is the average over the initial-state polarizations. In this limit Eq. (14.8) and Eq. (14.14) may be written in the form

$$\begin{aligned} \frac{d^2\sigma^i}{dxdy} &= \frac{2\pi\alpha^2}{xyQ^2} \eta^i \left[ Y_+ F_2^i \mp Y_- x F_3^i - y^2 F_L^i \right] \\ \frac{d^2\Delta\sigma^i}{dxdy} &= \frac{4\pi\alpha^2}{xyQ^2} \eta^i \left[ -Y_+ g_4^i \mp Y_- 2x g_1^i + y^2 g_L^i \right] \end{aligned} \quad (14.16)$$

with  $i = \text{NC or CC}$ , where  $Y_{\pm} = 1 \pm (1-y)^2$  and

$$F_L^i = F_2^i - 2x F_1^i, \quad g_L^i = g_4^i - 2x g_5^i. \quad (14.17)$$

In the naive quark-parton model, the analogy with the Callan-Gross relations [6]  $F_L^i = 0$ , are the Dicus relations [7]  $g_L^i = 0$ . Therefore, there are only two independent polarized structure functions:  $g_1$  (parity conserving) and  $g_5$  (parity violating), in analogy to the unpolarized structure functions  $F_1$  and  $F_3$ .

#### 14.2.1. Structure functions in the quark-parton model:

In the quark-parton model [8,9], contributions to the structure functions  $F^i$  and  $g^i$  can be expressed in terms of the quark distribution functions  $q(x, Q^2)$  of the proton, where  $q = u, \bar{u}, d, \bar{d}$  etc. The quantity  $q(x, Q^2)dx$  is the number of quarks (or antiquarks) of designated flavor that carry a momentum fraction between  $x$  and  $x + dx$  of the proton's momentum in a frame in which the proton momentum is large.

For the neutral-current processes  $ep \rightarrow eX$ ,

$$\begin{aligned} [F_2^\gamma, F_2^{\gamma Z}, F_2^Z] &= x \sum_q [e_q^2, 2e_q g_V^q, g_V^{q^2} + g_A^{q^2}] (q + \bar{q}), \\ [F_3^\gamma, F_3^{\gamma Z}, F_3^Z] &= \sum_q [0, 2e_q g_A^q, 2g_V^q g_A^q] (q - \bar{q}), \\ [g_1^\gamma, g_1^{\gamma Z}, g_1^Z] &= \frac{1}{2} \sum_q [e_q^2, 2e_q g_V^q, g_V^{q^2} + g_A^{q^2}] (\Delta q + \Delta \bar{q}), \\ [g_5^\gamma, g_5^{\gamma Z}, g_5^Z] &= \sum_q [0, e_q g_A^q, g_V^q g_A^q] (\Delta q - \Delta \bar{q}), \end{aligned} \quad (14.18)$$

where  $g_V^q = \pm \frac{1}{2} - 2e_q \sin^2 \theta_W$  and  $g_A^q = \pm \frac{1}{2}$  with  $\pm$  according to whether  $q$  is a  $u$ - or  $d$ -type quark respectively. The quantity  $\Delta q$  is the difference  $q \uparrow - q \downarrow$  of the distributions with the quark spin parallel and antiparallel to the proton spin.

## 6 14. Structure functions

For the charged-current processes  $e^-p \rightarrow \nu X$  and  $\bar{\nu}p \rightarrow e^+X$  the structure functions are:

$$\begin{aligned}
 F_2^{W^-} &= 2x(u + \bar{d} + \bar{s} + c \dots) , \\
 F_3^{W^-} &= 2(u - \bar{d} - \bar{s} + c \dots) , \\
 g_1^{W^-} &= (\Delta u + \Delta \bar{d} + \Delta \bar{s} + \Delta c \dots) , \\
 g_5^{W^-} &= (-\Delta u + \Delta \bar{d} + \Delta \bar{s} - \Delta c \dots) ,
 \end{aligned} \tag{14.19}$$

where only the active flavors are to be kept and where CKM mixing has been neglected. For  $e^+p \rightarrow \bar{\nu}X$  and  $\nu p \rightarrow e^-X$ , the structure functions  $F^{W^+}, g^{W^+}$  are obtained by the flavor interchanges  $d \leftrightarrow u, s \leftrightarrow c$  in the expressions for  $F^{W^-}, g^{W^-}$ . The structure functions for scattering on a neutron are obtained from those of the proton by the interchange  $u \leftrightarrow d$ . For both the neutral and charged-current processes, the quark-parton model predicts  $2xF_1^i = F_2^i$  and  $g_4^i = 2xg_5^i$ .

Neglecting masses, the structure functions  $g_2$  and  $g_3$  contribute only to scattering from transversely polarized nucleons (for which  $S \cdot q = 0$ ), and have no simple interpretation in terms of the quark-parton model. They arise from off-diagonal matrix elements  $\langle P, \lambda' | [J_\mu^\dagger(z), J_\nu(0)] | P, \lambda \rangle$ , where the proton helicities satisfy  $\lambda' \neq \lambda$ . In fact, the leading-twist contributions to both  $g_2$  and  $g_3$  are both twist-2 and twist-3, which contribute at the same order of  $Q^2$  (see the end of Sec. 14.2.2 for a definition of twist) . The Wandzura-Wilczek relation [10] expresses the twist-2 part of  $g_2$  in terms of  $g_1$

$$g_2^i(x) = -g_1^i(x) + \int_x^1 \frac{dy}{y} g_1^i(y) . \tag{14.20}$$

However the twist-3 component of  $g_2$  is unknown. Similarly there is a relation expressing the twist-2 part of  $g_3$  in terms of  $g_4$ . A complete set of relations, including  $M^2/Q^2$  effects, can be found in Ref. 11.

### 14.2.2. Structure functions and QCD:

One of the most striking predictions of the quark-parton model is that the structure functions  $F^i, g^i$  scale, *i.e.*,  $F^i(x, Q^2) \rightarrow F^i(x)$  in the Bjorken limit that  $Q^2$  and  $\nu \rightarrow \infty$  with  $x$  fixed [12]. This property is related to the assumption that the transverse momentum of the partons in the infinite-momentum frame of the proton is small. In QCD, however, the radiation of hard gluons from the quarks violates this assumption, leading to logarithmic scaling violations. The radiation of gluons produces the evolution of both the structure functions and the parton distribution functions. As  $Q^2$  increases, more and more gluons are radiated, which in turn split into  $q\bar{q}$  pairs. This process leads both to the softening of the initial quark momentum distributions and to the growth of the gluon density and the  $q\bar{q}$  sea as  $x$  decreases. The effects of the  $Q^2$  evolution can be seen in Fig. 14.2, where  $F_2$  is plotted at two values of  $Q^2$ .

**Figure 14.2:** The proton structure function  $F_2^p$  given at two  $Q^2$  values ( $3.5 \text{ GeV}^2$  and  $90 \text{ GeV}^2$ ), which exhibit scaling at the ‘pivot’ point  $x \sim 0.14$ . See the caption in Fig. 14.6 for the references of the data. Also shown is the MRST2001 parameterization [13] given at the same scales.

In QCD, the above process is described in terms of scale-dependent parton distributions  $f(x, \mu^2)$ , where  $f = g$  or  $q$  and, typically,  $\mu$  is the scale of the probe  $Q$ . These distributions correspond, at a given  $x$ , to the density of partons in the proton integrated over transverse momentum  $k_t$  up to  $\mu$ . Their evolution in  $\mu$  is described in QCD by the DGLAP equations (see Refs. [14,15,16,17]) which have the schematic form

$$\frac{\partial f}{\partial \ln \mu^2} \sim \frac{\alpha_s(\mu^2)}{2\pi} (P \otimes f) , \quad (14.21)$$

where  $\otimes$  denotes the convolution integral

$$P \otimes f = \int_x^1 \frac{dy}{y} P(y) f\left(\frac{x}{y}\right) . \quad (14.22)$$

Although perturbative QCD can predict, via Eq. (14.21), the evolution of the parton distribution functions from a particular scale,  $\mu_0$ , it cannot predict them *a priori* at any particular  $\mu_0$ . Thus they must be measured at a starting point  $\mu_0$  before the predictions of QCD can be compared to the data at other scales,  $\mu$ . In general, all observables

## 8 14. Structure functions

involving a hard hadronic interaction (such as structure functions) can be expressed as a convolution of calculable, process-dependent coefficient functions and these universal parton distributions.

It is often convenient to write the evolution equations in terms of the gluon, non-singlet ( $q^{NS}$ ) and singlet ( $q^S$ ) quark distributions, such that

$$q^{NS} = q_i - \bar{q}_i, \quad q^S = \sum_i (q_i + \bar{q}_i) . \quad (14.23)$$

The non-singlet distributions have non-zero values of flavor quantum numbers, such as isospin and baryon number. The DGLAP evolution equations then take the form

$$\begin{aligned} \frac{\partial q^{NS}}{\partial \ln \mu^2} &= \frac{\alpha_s(\mu^2)}{2\pi} P_{qq} \otimes q^{NS} , \\ \frac{\partial}{\partial \ln \mu^2} \begin{pmatrix} q^S \\ g \end{pmatrix} &= \frac{\alpha_s(\mu^2)}{2\pi} \begin{pmatrix} P_{qq} & 2n_f P_{qg} \\ P_{gq} & P_{gg} \end{pmatrix} \otimes \begin{pmatrix} q^S \\ g \end{pmatrix} , \end{aligned} \quad (14.24)$$

where  $P$  are splitting functions that describe the probability of a given parton splitting into two others, and  $n_f$  is the number of (active) quark flavors. The leading-order Altarelli-Parisi [16] splitting functions are

$$P_{qq} = \frac{4}{3} \left[ \frac{1+x^2}{(1-x)} \right]_+ = \frac{4}{3} \left[ \frac{1+x^2}{(1-x)_+} \right] + 2\delta(1-x) , \quad (14.25)$$

$$P_{qg} = \frac{1}{2} \left[ x^2 + (1-x)^2 \right] , \quad (14.26)$$

$$P_{gq} = \frac{4}{3} \left[ \frac{1+(1-x)^2}{x} \right] , \quad (14.27)$$

$$\begin{aligned} P_{gg} &= 6 \left[ \frac{1-x}{x} + x(1-x) + \frac{x}{(1-x)_+} \right] \\ &\quad + \left[ \frac{11}{2} - \frac{n_f}{3} \right] \delta(1-x) , \end{aligned} \quad (14.28)$$

where the notation  $[F(x)]_+$  defines a distribution such that for any sufficiently regular test function  $f(x)$

$$\int_0^1 dx f(x) [F(x)]_+ = \int_0^1 dx (f(x) - f(1)) F(x) . \quad (14.29)$$

In general, the structure functions can be expressed as a power series in  $\alpha_s$ . The series contains both terms proportional to  $\ln \mu^2$  and to  $\ln 1/x$ . The leading  $\ln \mu^2$  terms come, in an axial gauge, from evolution along the parton chain which is strongly ordered in transverse momenta, that is  $\mu^2 \gg k_{t,n}^2 \gg k_{t,n-1}^2 \gg \dots$ , where  $n$  denotes the  $n^{\text{th}}$  parton-branching process and  $k_t$  the parton transverse momentum. The leading-order

DGLAP evolution sums up the  $(\alpha_s \ln \mu^2)^n$  contributions. The next-to-leading order (NLO) sums up the  $\alpha_s(\alpha_s \ln \mu^2)^{n-1}$  terms [18,19], which arise when two adjacent  $k_{t,i}$ 's are no longer strongly ordered but become comparable, thereby losing a factor of  $\ln \mu^2$ . The NNLO contributions are now almost all known [20,21].

In the small  $x$  kinematic region it is essential to sum leading terms in  $\ln 1/x$ , independent of the value of  $\ln \mu^2$ . At leading order, this is done by the BFKL equation for the unintegrated distributions (see Refs. [22,23]). The leading-order  $(\alpha_s \ln(1/x))^n$  terms come from the configuration strongly ordered in  $x$ , *i.e.*,  $x \ll x_n \ll x_{n-1} \ll \dots$

In general, however, QCD color coherence implies *angular* ordering along the chain, so that it is necessary to work in terms of  $f_a(x, k_t^2, \mu^2)$ , the parton distributions unintegrated over  $k_t$ . These distributions depend on two hard scales:  $k_t$  and the scale  $\mu$  of the probe. Consequently they satisfy more complicated CCFM evolution equations [24,25]. The DGLAP and BFKL equations are two limits of angular-ordered evolution. In the DGLAP collinear approximation, the angle increases due to the growth of  $k_t$ , while, in the BFKL treatment, the angle ( $\theta \simeq k_t/k_l$ , where  $k_l$  is the longitudinal momentum) grows due to the decrease of the longitudinal-momentum fraction,  $x$ , along the chain of parton emissions from the proton.

As yet, there is no firm evidence in the data for  $Q^2 \gtrsim 2 \text{ GeV}^2$  for any deviation from standard DGLAP evolution, except that some DGLAP parton sets predict an unphysical behavior for  $F_L$  at low  $x$  [13].

The precision of the contemporary experimental data demands that NLO (or even NNLO) DGLAP evolution be used in comparisons between QCD theory and experiment. At higher orders, it is necessary to specify, and to use consistently, both a renormalization and a factorization scheme. Whereas the renormalization scheme used is almost universally the modified minimal subtraction ( $\overline{MS}$ ) scheme, there are two popular choices for factorization scheme, in which the form of the correction for each structure function is different. The two most-used factorization schemes are: DIS [26], in which there are no higher-order corrections to the  $F_2$  structure function, and  $\overline{MS}$  (based on Refs. [27,28,29]). They differ by how the higher-order gluon divergences are assimilated in the parton distribution functions.

Perturbative QCD predicts the  $Q^2$  behavior of leading-twist (twist-2) contributions to the structure functions. Higher-twist terms, which involve their own non-perturbative input, can occur. These die off as powers of  $Q$ ; specifically twist- $n$  terms are damped by  $1/Q^{n-2}$ . The higher-twist terms appear to be numerically unimportant for  $Q^2$  above a few  $\text{GeV}^2$ , except for  $x$  close to 1. At very large values of  $x$ , perturbative corrections proportional to  $\log(1-x)$  can become important [30].

So far, it has been assumed that the quarks are massless. The effects of the  $c$  and  $b$  quark masses on the evolution have been studied in Refs. 31–37. A variable flavor number approach is now generally adopted, in which evolution with  $n_f = 3$  is matched to that with  $n_f = 4$  at the charm threshold, with an analogous matching at the bottom threshold.

## 10 14. Structure functions

### 14.3. Determination of parton distributions

The parton distribution functions (PDFs) can be determined from data for deep inelastic lepton-nucleon scattering and for related hard-scattering processes initiated by nucleons. Table 14.1 given below (based on Ref. 38) highlights some processes and their primary sensitivity to PDFs.

**Table 14.1:** Lepton-nucleon and related hard-scattering processes and their primary sensitivity to the parton distributions that are probed.

Process	Main Subprocess	PDFs Probed
$\ell^\pm N \rightarrow \ell^\pm X$	$\gamma^* q \rightarrow q$	$g(x \lesssim 0.01), q, \bar{q}$
$\ell^+ (\ell^-) N \rightarrow \bar{\nu}(\nu) X$	$W^* q \rightarrow q'$	
$\nu(\bar{\nu}) N \rightarrow \ell^- (\ell^+) X$	$W^* q \rightarrow q'$	
$\nu N \rightarrow \mu^+ \mu^- X$	$W^* s \rightarrow c \rightarrow \mu^+$	$s$
$pp \rightarrow \gamma X$	$qg \rightarrow \gamma q$	$g(x \sim 0.4)$
$pN \rightarrow \mu^+ \mu^- X$	$q\bar{q} \rightarrow \gamma^*$	$\bar{q}$
$pp, pn \rightarrow \mu^+ \mu^- X$	$u\bar{u}, d\bar{d} \rightarrow \gamma^*$	$\bar{u} - \bar{d}$
	$u\bar{d}, d\bar{u} \rightarrow \gamma^*$	
$ep, en \rightarrow e\pi X$	$\gamma^* q \rightarrow q$	
$p\bar{p} \rightarrow W \rightarrow \ell^\pm X$	$ud \rightarrow W$	$u, d, u/d$
$p\bar{p} \rightarrow \text{jet} + X$	$gg, qg, qq \rightarrow 2j$	$q, g(0.01 \lesssim x \lesssim 0.5)$

The kinematic ranges of fixed-target and collider experiments are complementary (as is shown in Fig. 14.3) which enables the determination of PDFs over a wide range in  $x$  and  $Q^2$ . The unpolarized PDFs are determined through next-to-leading order global analyses of experimental data from such processes as those listed in the table above. See for example Refs. [13,39,40] for more detailed discussions of such global analyses. The result of one analysis is shown in Fig. 14.4 at a scale  $\mu^2 = 10 \text{ GeV}^2$ . The polarized PDFs are obtained through NLO global analyses of measurements of the  $g_1$  structure function in inclusive polarized deep inelastic scattering (see for example Refs. 41,42). The inclusive data do not provide enough observables to determine all polarized PDFs. These polarized PDFs may be fully accessed via flavor tagging in semi-inclusive deep inelastic scattering. Fig. 14.5 shows one global analysis at a scale of  $2.5 \text{ GeV}^2$  along with the data from semi-inclusive DIS.

Comprehensive sets of PDFs available as program-callable functions can be obtained from several sources *e.g.*, Refs. 45,46.

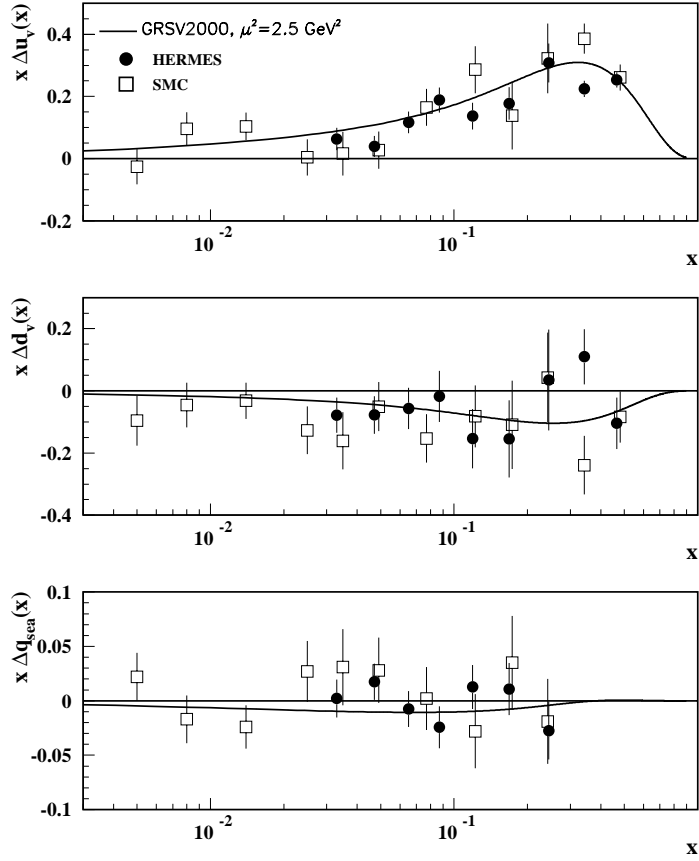

**Figure 14.3:** Kinematic domains in  $x$  and  $Q^2$  probed by fixed-target and collider experiments, shown together with the important constraints they make on the various parton distributions.

**Figure 14.4:** Distributions of  $x$  times the unpolarized parton distributions  $f(x)$  (where  $f = u_v, d_v, \bar{u}, \bar{d}, s, c, g$ ) using the MRST2001 parameterization [13] at a scale  $\mu^2 = 10 \text{ GeV}^2$ .

## 12 14. Structure functions

**Figure 14.5:** Distributions of  $x$  times the polarized parton distributions  $\Delta q(x)$  (where  $q = u_v, d_v, q_{sea}$ ) using the GRSV2000 parameterization [42] at a scale  $\mu^2 = 2.5 \text{ GeV}^2$ . Points represent data from semi-inclusive positron (HERMES [43]) and muon (SMC [44]) deep inelastic scattering given at  $Q^2 = 2.5 \text{ GeV}^2$ .

#### 14.4. DIS determinations of $\alpha_s$

In the fits to the DIS data,  $\alpha_s(M_Z^2)$  is often left as a free parameter. For example, a recent NLO DGLAP fit by H1 [47] to their  $F_2$  measurements, together with those of BCDMS, gives

$$\alpha_s(M_Z^2) = 0.1150 \pm 0.0017(\text{expt})_{-0.0005}^{+0.0009}(\text{model}) \pm 0.005(\text{theory}). \quad (14.30)$$

There is a strong correlation between the value found for  $\alpha_s$  and the behavior of the gluon distribution. A NLO global analysis [13] which includes all the latest unpolarized DIS data, together with recent Tevatron jet data to constrain the large  $x$  gluon distribution, finds

$$\alpha_s(M_Z^2) = 0.119 \pm 0.002(\text{expt}) \pm 0.003(\text{theory}). \quad (14.31)$$

Interestingly, even if the jet data were omitted in this global fit, result Eq. (14.31) is still obtained.

There have been several studies of  $\alpha_s$  at NNLO, and beyond, using subsets of DIS data (see Refs. 48–51). Moreover there exist global NLO analyses of polarised DIS data which give  $\alpha_s(M_Z^2) = 0.120 \pm 0.009$  [52] and  $0.114 \pm 0.009$  [53].

---

\* The value of  $\eta^{\text{CC}}$  deduced from Ref. 1 is found to be a factor of two too small;  $\eta^{\text{CC}}$  of Eq. (14.9) agrees with Refs. 2,3.
