\* This *Particle Physics Booklet* includes the Summary Tables plus essential tables, figures, and equations from selected review articles. The table of contents, on the following pages, lists also additional material available in the full *Review*.

## PARTICLE PHYSICS BOOKLET TABLE OF CONTENTS

1. Physical constants . . . . .	6
2. Astrophysical constants . . . . .	8
<b>Summary Tables of Particle Physics</b>	
Gauge and Higgs bosons . . . . .	10
Leptons . . . . .	16
Quarks . . . . .	25
Mesons . . . . .	27
Baryons . . . . .	155
Searches not in other sections . . . . .	184
Tests of conservation laws . . . . .	188
<b>Reviews, Tables, and Plots</b>	
9. Quantum chromodynamics . . . . .	191
10. Electroweak model and constraints on new physics . . . . .	192
11. Higgs boson physics, status of . . . . .	194
12. CKM quark-mixing matrix . . . . .	196
13. <i>CP</i> violation in the quark sector . . . . .	198
14. Neutrino mass, mixing and oscillations . . . . .	200
15. Quark model . . . . .	202
21. Big-bang cosmology . . . . .	203
26. Dark matter . . . . .	205
28. Cosmic microwave background . . . . .	206
29. Cosmic rays . . . . .	208
30. Accelerator physics of colliders . . . . .	209
31. High-energy collider parameters . . . . .	211
33. Passage of particles through matter . . . . .	212
34. Particle detectors at accelerators . . . . .	219
36. Radioactivity and radiation protection . . . . .	220
37. Commonly used radioactive sources . . . . .	222
38. Probability . . . . .	224
39. Statistics . . . . .	228
44. Clebsch-Gordan coefficients, spherical harmonics, and <i>d</i> functions . . . . .	234
47. Kinematics . . . . .	236
49. Cross-section formulae for specific processes . . . . .	244
50. Neutrino cross-section measurements . . . . .	249
6. Atomic and nuclear properties of materials . . . . .	250
4. Periodic table of the elements . . . . .	inside back cover

The following are found only in the full *Review*, see

<http://pdg.lbl.gov>

## VOLUME 1: SUMMARY TABLES AND REVIEWS

Highlights

Introduction

History plots

Online particle physics information

### Reviews, Tables, and Plots

#### Constants, Units, Atomic and Nuclear Properties

3. International system of units (SI)
5. Electronic structure of the elements
7. Electromagnetic relations
8. Naming scheme for hadrons

#### Standard Model and Related Topics

16. Heavy-quark & soft-collinear effective theory
17. Lattice quantum chromodynamics
18. Structure functions
19. Fragmentation functions in  $e^+e^-$ ,  $ep$  and  $pp$  collisions

#### Astrophysics and Cosmology

20. Experimental tests of gravitational theory
22. Inflation
23. Big-bang nucleosynthesis
24. Cosmological parameters
25. Neutrinos in cosmology
27. Dark energy

#### Experimental Methods and Colliders

32. Neutrino beam lines at high-energy proton synchrotrons
35. Particle detectors for non-accelerator physics

#### Mathematical Tools

40. Monte Carlo techniques
41. Monte Carlo event generators
42. Monte Carlo neutrino event generators
43. Monte Carlo particle numbering scheme
45. SU(3) isoscalar factors and representation matrices
46. SU( $n$ ) multiplets and Young diagrams

#### Kinematics, Cross-Section Formulae, and Plots

48. Resonances
51. Plots of cross sections and related quantities

#### Particle Properties

##### Gauge Bosons

52. Mass and width of the  $W$  boson
53. Extraction of triple gauge couplings (TGC's)
54. Anomalous  $W/Z$  quartic couplings
55.  $Z$  boson
56. Anomalous  $ZZ\gamma$ ,  $Z\gamma\gamma$ , and  $ZZV$  couplings

##### Leptons

57. Muon anomalous magnetic moment
58. Muon decay parameters
59.  $\tau$  branching fractions
60.  $\tau$ -lepton decay parameters
61. Number of light neutrino types from collider experiments

- 62. Neutrinoless double- $\beta$  decay
- 63. Neutrino properties
- 64. Sum of neutrino masses
- 65. Three-neutrino mixing parameters

### Quarks

- 66. Quark masses
- 67. Top quark

### Mesons

- 68. Form factors for radiative pion & kaon decays
- 69. Scalar mesons below 2 GeV
- 70.  $\rho(770)$
- 71. Pseudoscalar and pseudovector mesons in the 1400 MeV region
- 72.  $\rho(1450)$  and the  $\rho(1700)$
- 73. Charged kaon mass
- 74. Rare kaon decays
- 75. Dalitz plot parameters for  $K \rightarrow 3\pi$  decays
- 76.  $K_{\ell 3}^\pm$  and  $K_{\ell 3}^0$  form factors
- 77. *CPT* invariance tests in neutral kaon decay
- 78. *CP*-violation in  $K_S \rightarrow 3\pi$
- 79.  $V_{ud}$ ,  $V_{us}$ , Cabibbo angle, and CKM unitarity
- 80. *CP*-violation in  $K_L$  decays
- 81. Review of multibody charm analyses
- 82.  $D^0$ - $\overline{D}^0$  mixing
- 83.  $D_s^+$  branching fractions
- 84. Leptonic decays of charged pseudoscalar mesons
- 85. Production and decay of  $b$ -flavored hadrons
- 86. Heavy Flavor Averaging Group
- 87. Polarization in  $B$  decays
- 88.  $B^0$ - $\overline{B}^0$  mixing
- 89. Semileptonic  $B$  decays,  $V_{cb}$  and  $V_{ub}$
- 90. Spectroscopy of mesons containing two heavy quarks
- 91. Charmonium system
- 92. Branching ratios of  $\psi(2S)$  and  $\chi_{c0,1,2}$
- 93. Bottomonium system
- 94. Width determination of the  $\Upsilon$  states
- 95. Non- $q\bar{q}$  mesons

### Baryons

- 96. Baryon decay parameters
- 97.  $N$  and  $\Delta$  resonances
- 98. Baryon magnetic moments
- 99.  $\Lambda$  and  $\Sigma$  resonances
- 100. Pole structure of the  $\Lambda(1405)$  region
- 101.  $\Sigma(1670)$  region
- 102. Radiative hyperon decays
- 103.  $\Xi$  resonances
- 104. Charmed baryons
- 105. Pentaquarks

### Hypothetical Particles and Concepts

- 106. Extra dimensions
- 107.  $W'$ -boson searches
- 108.  $Z'$ -boson searches
- 109. Supersymmetry: theory

- 110. Supersymmetry: experiment
- 111. Axions and other similar particles
- 112. Quark and lepton compositeness, searches for
- 113. Dynamical electroweak symmetry breaking:  
implications of the  $H^0$
- 114. Grand unified theories
- 115. Leptoquarks
- 116. Magnetic monopoles

## **VOLUME 2: PARTICLE LISTINGS** (available online only)

### **Illustrative key and abbreviations**

Illustrative key

Abbreviations

### **Gauge and Higgs bosons**

( $\gamma$ , gluon, graviton,  $W$ ,  $Z$ , Higgs, Axions)

### **Leptons**

( $e$ ,  $\mu$ ,  $\tau$ , Heavy-charged lepton searches,  
Neutrino properties, Number of neutrino types  
Double- $\beta$  decay, Neutrino mixing,  
Heavy-neutral lepton searches)

### **Quarks**

( $u$ ,  $d$ ,  $s$ ,  $c$ ,  $b$ ,  $t$ ,  $b'$ ,  $t'$  ( $4^{th}$  gen.), Free quarks)

### **Mesons**

Light unflavored ( $\pi$ ,  $\rho$ ,  $a$ ,  $b$ ) ( $\eta$ ,  $\omega$ ,  $f$ ,  $\phi$ ,  $h$ )  
Other light unflavored  
Strange ( $K$ ,  $K^*$ )  
Charmed ( $D$ ,  $D^*$ )  
Charmed, strange ( $D_s$ ,  $D_s^*$ ,  $D_{sJ}$ )  
Bottom ( $B$ ,  $V_{cb}/V_{ub}$ ,  $B^*$ ,  $B_J^*$ )  
Bottom, strange ( $B_s$ ,  $B_s^*$ ,  $B_{sJ}^*$ )  
Bottom, charmed ( $B_c$ )  
 $c\bar{c}$  ( $\eta_c$ ,  $J/\psi(1S)$ ,  $\chi_c$ ,  $h_c$ ,  $\psi$ )  
 $b\bar{b}$  ( $\eta_b$ ,  $\Upsilon$ ,  $\chi_b$ ,  $h_b$ )

### **Baryons**

$N$   
 $\Delta$   
 $\Lambda$   
 $\Sigma$   
 $\Xi$   
 $\Omega$

Charmed ( $\Lambda_c$ ,  $\Sigma_c$ ,  $\Xi_c$ ,  $\Omega_c$ )  
Doubly charmed ( $\Xi_{cc}$ )  
Bottom ( $\Lambda_b$ ,  $\Sigma_b$ ,  $\Xi_b$ ,  $\Omega_b$ ,  $b$ -baryon admixture)  
Exotic baryons ( $P_c$  pentaquarks)

### **Searches not in Other Sections**

Magnetic monopole searches  
Supersymmetric particle searches  
Technicolor  
Searches for quark and lepton compositeness  
Extra dimensions  
WIMP and dark matter searches  
Other particle searches

## 6 1. Physical constants

**Table 1.1.** Reviewed 2015 by P.J. Mohr and D.B. Newell (NIST). Mainly from CODATA recommended values, Rev. Mod. Phys. **88**, 035009 (2016). The last group, beginning with the Fermi coupling constant, comes from Particle Data Group 2018 update. The  $1\sigma$  uncertainties in the last digits are given in parentheses after the values. See the full edition of this *Review* for references and further explanation.

Quantity	Symbol, equation	Value	Uncertainty (ppb)
speed of light in vacuum	$c$	299 792 458 m s $^{-1}$	exact
Planck constant	$h$	6.626 070 040(81) $\times 10^{-34}$ J s	12
Planck constant, reduced	$\hbar \equiv h/2\pi$	1.054 571 800(13) $\times 10^{-34}$ J s	12
		$= 6.582 119 514(40) \times 10^{-22}$ MeV s	6.1
electron charge magnitude	$e$	1.602 176 6208(98) $\times 10^{-19}$ C	$= 4.803 204 673(30) \times 10^{-10}$ esu
conversion constant	$\hbar c$	6.1	6.1
conversion constant	$(\hbar c)^2$	197 326 9788(12) MeV fm	6.1
		0.389 379 3656(48) GeV $^2$ mbarn	12
electron mass	$m_e$	0.510 998 9461(31) MeV/c $^2$	$= 9.109 383 56(11) \times 10^{-31}$ kg
proton mass	$m_p$	938.272 0813(58) MeV/c $^2$	$= 1.672 621 898(21) \times 10^{-27}$ kg
		$= 1.007 276 466 879(91)$ u	$= 1836.152 673 89(17)$ $m_e$
		0.090, 0.095	0.090, 0.095
deuteron mass	$m_d$	1875.612 928(12) MeV/c $^2$	6.2
unified atomic mass unit (u)	(mass $^{12}\text{C}$ atom)/12 = (1 g)/( $N_A$ mol)	931.494 0954(57) MeV/c $^2$	$= 1.660 539 040(20) \times 10^{-27}$ kg
permittivity of free space	$\epsilon_0 = 1/\mu_0 c^2$	8.854 187 817 ... $\times 10^{-12}$ F m $^{-1}$	exact
permeability of free space	$\mu_0$	$4\pi \times 10^{-7}$ N A $^{-2} = 12.566 370 614 \dots \times 10^{-7}$ N A $^{-2}$	exact
fine-structure constant	$\alpha = e^2/4\pi\epsilon_0\hbar c$	7.297 352 5664(17) $\times 10^{-3} = 1/137.035 999 139(31)$	0.23, 0.23
		At $Q^2 = 0$ . At $Q^2 \approx m^2(W)$ the value is $\sim 1/128$ .	
classical electron radius	$r_e = e^2/4\pi\epsilon_0 m_e c^2$	2.817 940 3227(19) $\times 10^{-15}$ m	0.68
( $e^-$ Compton wavelength)/ $2\pi$	$\lambda_e = \hbar/m_e c = r_e \alpha^{-1}$	3.861 592 6764(18) $\times 10^{-13}$ m	0.45
Bohr radius ( $m_{\text{nucleus}} = \infty$ )	$a_\infty = 4\pi\epsilon_0\hbar^2/m_e e^2 = r_e \alpha^{-2}$	0.529 177 210 67(12) $\times 10^{-10}$ m	0.23
wavelength of 1 eV/c particle	$hc/(1 \text{ eV})$	1.239 841 9739(76) $\times 10^{-6}$ m	6.1
Rydberg energy	$hcR_\infty = m_e e^4/2(4\pi\epsilon_0)^2 \hbar^2 = m_e c^2 \alpha^2/2$	13.605 693 009(84) eV	6.1
Thomson cross section	$\sigma_T = 8\pi r_e^2/3$	0.665 245 871 58(91) barn	1.4

Bohr magneton	$\mu_B = e\hbar/2m_e$	5.788 381 8012(26) $\times 10^{-11}$ MeV T $^{-1}$	0.45
nuclear magneton	$\mu_N = e\hbar/2m_p$	3.152 451 2550(15) $\times 10^{-14}$ MeV T $^{-1}$	0.46
electron cyclotron freq./field	$\omega_{\text{cycl}}^e/B = e/m_e$	1.758 820 024(11) $\times 10^{11}$ rad s $^{-1}$ T $^{-1}$	6.2
proton cyclotron freq./field	$\omega_{\text{cycl}}^p/B = e/m_p$	9.578 833 226(59) $\times 10^7$ rad s $^{-1}$ T $^{-1}$	6.2

## New Heavy Bosons ( $W'$ , $Z'$ , leptoquarks, etc.), Searches for

### Additional $W$ Bosons

$W'$  with standard couplings

Mass  $m > 4.100 \times 10^3$  GeV, CL = 95% ( $pp$  direct search)

$W_R$  (Right-handed  $W$  Boson)

Mass  $m > 715$  GeV, CL = 90% (electroweak fit)

### Additional $Z$ Bosons

$Z'_{SM}$  with standard couplings

Mass  $m > 4.500 \times 10^3$  GeV, CL = 95% ( $pp$  direct search)

$Z_{LR}$  of  $SU(2)_L \times SU(2)_R \times U(1)$  (with  $g_L = g_R$ )

Mass  $m > 630$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 1162$  GeV, CL = 95% (electroweak fit)

$Z_\chi$  of  $SO(10) \rightarrow SU(5) \times U(1)_\chi$  (with  $g_\chi = e/\cos\theta_W$ )

Mass  $m > 4.100 \times 10^3$  GeV, CL = 95% ( $pp$  direct search)

$Z_\psi$  of  $E_6 \rightarrow SO(10) \times U(1)_\psi$  (with  $g_\psi = e/\cos\theta_W$ )

Mass  $m > 3.800 \times 10^3$  GeV, CL = 95% ( $pp$  direct search)

$Z_\eta$  of  $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$  (with  $g_\eta = e/\cos\theta_W$ )

Mass  $m > 3.900 \times 10^3$  GeV, CL = 95% ( $pp$  direct search)

### Scalar Leptoquarks

Mass  $m > 1050$  GeV, CL = 95% (1st generation, pair prod.)

Mass  $m > 1755$  GeV, CL = 95% (1st generation, single prod.)

Mass  $m > 1080$  GeV, CL = 95% (2nd generation, pair prod.)

Mass  $m > 660$  GeV, CL = 95% (2nd generation, single prod.)

Mass  $m > 850$  GeV, CL = 95% (3rd generation, pair prod.)

(See the Particle Listings in the Full Review of Particle Physics for assumptions on leptoquark quantum numbers and branching fractions.)

### Diquarks

Mass  $m > 6000$  GeV, CL = 95% ( $E_6$  diquark)

### Axigluon

Mass  $m > 5500$  GeV, CL = 95%

## Axions ( $A^0$ ) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full Review contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is  $> 7.2 \times 10^{24}$  years (CL = 90%).

## NOTES

In this Summary Table:

When a quantity has “(S = ...)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as  $S = \sqrt{\chi^2/(N - 1)}$ , where N is the number of measurements used in calculating the quantity.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b]  $\ell$  indicates each type of lepton ( $e$ ,  $\mu$ , and  $\tau$ ), not sum over them.
- [c] This represents the width for the decay of the  $W$  boson into a charged particle with momentum below detectability,  $p < 200$  MeV.
- [d] The  $Z$ -boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the  $Z$ -boson propagator.
- [e] This partial width takes into account  $Z$  decays into  $\nu\bar{\nu}$  and any other possible undetected modes.
- [f] This ratio has not been corrected for the  $\tau$  mass.
- [g] Here  $A \equiv 2g_V g_A / (g_V^2 + g_A^2)$ .
- [h] This parameter is not directly used in the overall fit but is derived using the fit results; see the note “The  $Z$  boson” and ref. LEP-SLC 06 (Physics Reports (Physics Letters C) **427** 257 (2006)).
- [i] Here  $\ell$  indicates  $e$  or  $\mu$ .
- [j] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [k] This value is updated using the product of (i) the  $Z \rightarrow b\bar{b}$  fraction from this listing and (ii) the  $b$ -hadron fraction in an unbiased sample of weakly decaying  $b$ -hadrons produced in  $Z$ -decays provided by the Heavy Flavor Averaging Group (HFLAV, [http://www.slac.stanford.edu/xorg/hflav/osc/PDG\\_2009/#FRACZ](http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ)).
- [l] See the  $Z$  Particle Listings in the Full Review of Particle Physics for the  $\gamma$  energy range used in this measurement.
- [n] For  $m_{\gamma\gamma} = (60 \pm 5)$  GeV.
- [o] The limits assume no invisible decays.

# LEPTONS

**e**

$$J = \frac{1}{2}$$

Mass  $m = (548.579909070 \pm 0.000000016) \times 10^{-6}$  u

Mass  $m = 0.5109989461 \pm 0.000000031$  MeV

$|m_{e^+} - m_{e^-}|/m < 8 \times 10^{-9}$ , CL = 90%

$|q_{e^+} + q_{e^-}|/e < 4 \times 10^{-8}$

Magnetic moment anomaly

$(g-2)/2 = (1159.65218091 \pm 0.00000026) \times 10^{-6}$

$(g_{e^+} - g_{e^-}) / g_{\text{average}} = (-0.5 \pm 2.1) \times 10^{-12}$

Electric dipole moment  $d < 0.87 \times 10^{-28}$  e cm, CL = 90%

Mean life  $\tau > 6.6 \times 10^{28}$  yr, CL = 90% [a]

 **$\mu$** 

$$J = \frac{1}{2}$$

Mass  $m = 0.1134289257 \pm 0.0000000025$  u

Mass  $m = 105.6583745 \pm 0.0000024$  MeV

Mean life  $\tau = (2.1969811 \pm 0.0000022) \times 10^{-6}$  s

$\tau_{\mu^+}/\tau_{\mu^-} = 1.00002 \pm 0.00008$

$c\tau = 658.6384$  m

Magnetic moment anomaly  $(g-2)/2 = (11659209 \pm 6) \times 10^{-10}$

$(g_{\mu^+} - g_{\mu^-}) / g_{\text{average}} = (-0.11 \pm 0.12) \times 10^{-8}$

Electric dipole moment  $d = (-0.1 \pm 0.9) \times 10^{-19}$  e cm

## Decay parameters [b]

$\rho = 0.74979 \pm 0.00026$

$\eta = 0.057 \pm 0.034$

**Lepton Family number (*LF*), Lepton number (*L*), or Baryon number (*B*) violating modes**

*L* means lepton number violation (e.g.  $\tau^- \rightarrow e^+ \pi^- \pi^-$ ). Following common usage, *LF* means lepton family violation and *not* lepton number violation (e.g.  $\tau^- \rightarrow e^- \pi^+ \pi^-$ ). *B* means baryon number violation.

## Heavy Charged Lepton Searches

### $L^\pm$ – charged lepton

Mass  $m > 100.8$  GeV, CL = 95% [h] Decay to  $\nu W$ .

### $L^\pm$ – stable charged heavy lepton

Mass  $m > 102.6$  GeV, CL = 95%

## Neutrino Properties

See the note on “Neutrino properties listings” in the Particle Listings.

Mass  $m < 2$  eV (tritium decay)

Mean life/mass,  $\tau/m > 300$  s/eV, CL = 90% (reactor)

Mean life/mass,  $\tau/m > 7 \times 10^9$  s/eV (solar)

Mean life/mass,  $\tau/m > 15.4$  s/eV, CL = 90% (accelerator)

Magnetic moment  $\mu < 0.29 \times 10^{-10} \mu_B$ , CL = 90% (reactor)

## Number of Neutrino Types

Number  $N = 2.984 \pm 0.008$  (Standard Model fits to LEP-SLC data)

Number  $N = 2.92 \pm 0.05$  ( $S = 1.2$ ) (Direct measurement of invisible  $Z$  width)

## Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review “Neutrino Mass, Mixing, and Oscillations” by K. Nakamura and S.T. Petcov in this *Review*.

$$\sin^2(\theta_{12}) = 0.307 \pm 0.013$$

$$\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$$

$$\sin^2(\theta_{23}) = 0.421^{+0.033}_{-0.025} \quad (S = 1.3) \quad (\text{Inverted order, quad. I})$$

$$\sin^2(\theta_{23}) = 0.592^{+0.023}_{-0.030} \quad (S = 1.1) \quad (\text{Inverted order, quad. II})$$

$$\sin^2(\theta_{23}) = 0.417^{+0.025}_{-0.028} \quad (S = 1.2) \quad (\text{Normal order, quad. I})$$

$$\sin^2(\theta_{23}) = 0.597^{+0.024}_{-0.030} \quad (S = 1.2) \quad (\text{Normal order, quad. II})$$

$$\Delta m_{32}^2 = (-2.56 \pm 0.04) \times 10^{-3} \text{ eV}^2 \quad (\text{Inverted order})$$

$$\Delta m_{32}^2 = (2.51 \pm 0.05) \times 10^{-3} \text{ eV}^2 \quad (S = 1.1) \quad (\text{Normal order})$$

$$\sin^2(\theta_{13}) = (2.12 \pm 0.08) \times 10^{-2}$$

## Stable Neutral Heavy Lepton Mass Limits

Mass  $m > 45.0$  GeV, CL = 95% (Dirac)

Mass  $m > 39.5$  GeV, CL = 95% (Majorana)

## Neutral Heavy Lepton Mass Limits

Mass  $m > 90.3$  GeV, CL = 95%

(Dirac  $\nu_L$  coupling to  $e, \mu, \tau$ ; conservative case( $\tau$ ))

Mass  $m > 80.5$  GeV, CL = 95%

(Majorana  $\nu_L$  coupling to  $e, \mu, \tau$ ; conservative case( $\tau$ ))

## NOTES

In this Summary Table:

When a quantity has “(S = . . .)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as  $S = \sqrt{\chi^2/(N - 1)}$ , where N is the number of measurements used in calculating the quantity.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] This is the best limit for the mode  $e^- \rightarrow \nu\gamma$ . The best limit for “electron disappearance” is  $6.4 \times 10^{24}$  yr.
- [b] See the “Note on Muon Decay Parameters” in the  $\mu$  Particle Listings in the *Full Review of Particle Physics* for definitions and details.
- [c]  $P_\mu$  is the longitudinal polarization of the muon from pion decay. In standard V-A theory,  $P_\mu = 1$  and  $\rho = \delta = 3/4$ .
- [d] This only includes events with energy of  $e > 45$  MeV and energy of  $\gamma > 40$  MeV. Since the  $e^- \bar{\nu}_e \nu_\mu$  and  $e^- \bar{\nu}_e \nu_\mu \gamma$  modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [e] See the relevant Particle Listings in the *Full Review of Particle Physics* for the energy limits used in this measurement.
- [f] A test of additive vs. multiplicative lepton family number conservation.
- [g] Basis mode for the  $\tau$ .
- [h]  $L^\pm$  mass limit depends on decay assumptions; see the Full Listings.

## QUARKS

The  $u$ -,  $d$ -, and  $s$ -quark masses are estimates of so-called “current-quark masses,” in a mass-independent subtraction scheme such as  $\overline{\text{MS}}$  at a scale  $\mu \approx 2$  GeV. The  $c$ - and  $b$ -quark masses are the “running” masses in the  $\overline{\text{MS}}$  scheme. This can be different from the heavy quark masses obtained in potential models.

**u**

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

$$m_u = 2.2^{+0.5}_{-0.4} \text{ MeV} \quad \text{Charge} = \frac{2}{3} e \quad I_z = +\frac{1}{2}$$

$$m_u/m_d = 0.48^{+0.07}_{-0.08}$$

**d**

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

$$m_d = 4.7^{+0.5}_{-0.3} \text{ MeV} \quad \text{Charge} = -\frac{1}{3} e \quad I_z = -\frac{1}{2}$$

$$m_s/m_d = 17-22$$

$$\overline{m} = (m_u + m_d)/2 = 3.5^{+0.5}_{-0.2} \text{ MeV}$$

**s**

$$I(J^P) = 0(\frac{1}{2}^+)$$

$$m_s = 95^{+9}_{-3} \text{ MeV} \quad \text{Charge} = -\frac{1}{3} e \quad \text{Strangeness} = -1$$

All searches since 1977 have had negative results.

**NOTES**

[a] A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

[b] Based on published top mass measurements using data from Tevatron Run-I and Run-II and LHC at  $\sqrt{s} = 7$  TeV. Including the most recent unpublished results from Tevatron Run-II, the Tevatron Electroweak Working Group reports a top mass of  $173.2 \pm 0.9$  GeV. See the note "The Top Quark" in the Quark Particle Listings of this Review.

[c] This limit is for  $\Gamma(t \rightarrow Z q)/\Gamma(t \rightarrow W b)$ .

\end{aligned}$$

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\overline{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\overline{K}^0)$ .

### **CP-even fractions (labeled by the $D^0$ decay)**

$$\begin{aligned}
&\text{CP-even fraction in } D^0 \rightarrow \pi^+ \pi^- \pi^0 \text{ decays} = (97.3 \pm 1.7)\% \\
&\text{CP-even fraction in } D^0 \rightarrow K^+ K^- \pi^0 \text{ decays} = (73 \pm 6)\% \\
&\text{CP-even fraction in } D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^- \text{ decays} = (73.7 \pm 2.8)\% \\
&\text{CP-even fraction in } D^0 \rightarrow K^+ K^- \pi^+ \pi^- \text{ decays} = (75 \pm 4)\%
\end{aligned}$$

### **CP-violation asymmetry difference**

$$\Delta A_{CP} = A_{CP}(K^+ K^-) - A_{CP}(\pi^+ \pi^-) = (-0.12 \pm 0.13)\% \quad (\text{S} = 1.8)$$

**$\chi^2$  tests of CP-violation (CPV)**

Local CPV in  $D^0, \bar{D}^0 \rightarrow \pi^+ \pi^- \pi^0 = 4.9\%$

Local CPV in  $D^0, \bar{D}^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^- = (0.6 \pm 0.2)\%$

Local CPV in  $D^0, \bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^- = 96\%$

Local CPV in  $D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^0 = 16.6\%$

Local CPV in  $D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^- = 9.1\%$

**T-violation decay-rate asymmetry**

$A_T(K^+ K^- \pi^+ \pi^-) = (1.7 \pm 2.7) \times 10^{-3}$  [ss]

$A_{T\text{viol}}(K_S \pi^+ \pi^- \pi^0)$  in  $D^0, \bar{D}^0 \rightarrow K_S \pi^+ \pi^- \pi^0 = (-0.3^{+1.4}_{-1.6}) \times 10^{-3}$

**CPT-violation decay-rate asymmetry**

$A_{CPT}(K^\mp \pi^\pm) = 0.008 \pm 0.008$

**Form factors**

$r_V \equiv V(0)/A_1(0)$  in  $D^0 \rightarrow K^*(892)^- \ell^+ \nu_\ell = 1.7 \pm 0.8$

$r_2 \equiv A_2(0)/A_1(0)$  in  $D^0 \rightarrow K^*(892)^- \ell^+ \nu_\ell = 0.9 \pm 0.4$

$f_+(0)$  in  $D^0 \rightarrow K^- \ell^+ \nu_\ell = 0.736 \pm 0.004$

$f_+(0)|V_{cs}|$  in  $D^0 \rightarrow K^- \ell^+ \nu_\ell = 0.719 \pm 0.004$

$r_1 \equiv a_1/a_0$  in  $D^0 \rightarrow K^- \ell^+ \nu_\ell = -2.40 \pm 0.16$

$r_2 \equiv a_2/a_0$  in  $D^0 \rightarrow K^- \ell^+ \nu_\ell = 5 \pm 4$

$f_+(0)$  in  $D^0 \rightarrow \pi^- \ell^+ \nu_\ell = 0.637 \pm 0.009$

$f_+(0)|V_{cd}|$  in  $D^0 \rightarrow \pi^- \ell^+ \nu_\ell = 0.1436 \pm 0.0026$  ( $S = 1.5$ )

$r_1 \equiv a_1/a_0$  in  $D^0 \rightarrow \pi^- \ell^+ \nu_\ell = -1.97 \pm 0.28$  ( $S = 1.4$ )

$r_2 \equiv a_2/a_0$  in  $D^0 \rightarrow \pi^- \ell^+ \nu_\ell = -0.2 \pm 2.2$  ( $S = 1.7$ )

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

$B^-$  modes are charge conjugates of the modes below. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0 \overline{B}^0$  and 50%  $B^+ B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D$ ,  $D_S$ ,  $D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

## 74 Meson Summary Table

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

\end{aligned}$$

$\bar{B}^0$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0\bar{B}^0$  and 50%  $B^+B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D$ ,  $D_S$ ,  $D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

\end{aligned}$$

The branching fraction measurements are for an admixture of  $B$  mesons at the  $\Upsilon(4S)$ . The values quoted assume that  $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$ .

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{anything}$ , the treatment of multiple  $D$ 's in the final state must be defined. One possibility would be to count the number of events with one-or-more  $D$ 's and divide by the total number of  $B$ 's. Another possibility would be to count the total number of  $D$ 's and divide by the total number of  $B$ 's, which is the definition of average multiplicity. The two definitions are identical if only one  $D$  is allowed in the final state.

Even though the “one-or-more” definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the  $B$  sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

$\bar{B}$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

### **$B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE**

These measurements are for an admixture of bottom particles at high energy (LHC, LEP, Tevatron,  $Sp\bar{p}S$ ).

$$\text{Mean life } \tau = (1.566 \pm 0.003) \times 10^{-12} \text{ s}$$

Mean life  $\tau = (1.72 \pm 0.10) \times 10^{-12} \text{ s}$  Charged *b*-hadron admixture

Mean life  $\tau = (1.58 \pm 0.14) \times 10^{-12} \text{ s}$  Neutral *b*-hadron admixture

$$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$$

$$|\Delta\tau_b|/\tau_{b,\bar{b}} = -0.001 \pm 0.014$$

$$\text{Re}(\epsilon_b) / (1 + |\epsilon_b|^2) = (-1.3 \pm 0.4) \times 10^{-3}$$

The branching fraction measurements are for an admixture of *B* mesons and baryons at energies above the  $\Upsilon(4S)$ . Only the highest energy results (LHC, LEP, Tevatron,  $Sp\bar{p}S$ ) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a  $\bar{B}$  initial state. *b* modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

<b><math>\bar{b}</math> DECAY MODES</b>	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level	$p$ (MeV/c)
---	--------------------------------	-----------------------------------	----------------

## PRODUCTION FRACTIONS

The production fractions for weakly decaying  $b$ -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFLAV) as described in the note “ $B^0$ - $\bar{B}^0$  Mixing” in the  $B^0$  Particle Listings. The production fractions in  $b$ -hadronic  $Z$  decay or  $p\bar{p}$  collisions at the Tevatron are also listed at the end of the section. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0)$$

$$B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The correlation coefficients between production fractions are also reported:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.259$$

$$\text{cor}(B_s^0, B^\pm = B^0) = -0.133$$

$$\text{cor}(b\text{-baryon}, B^\pm = B^0) = -0.923.$$

The notation for production fractions varies in the literature ( $f_d$ ,  $d_{B^0}$ ,  $f(b \rightarrow \bar{B}^0)$ ,  $\text{Br}(b \rightarrow \bar{B}^0)$ ). We use our own branching fraction notation here,  $B(\bar{b} \rightarrow B^0)$ .

Note these production fractions are  $b$ -hadronization fractions, not the conventional branching fractions of  $b$ -quark to a  $B$ -hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

$B^+$	( 40.5 $\pm$ 0.6 ) %	—
$B^0$	( 40.5 $\pm$ 0.6 ) %	—
$B_s^0$	( 10.1 $\pm$ 0.4 ) %	—

$$\Delta a_X = (1.0 \pm 2.2) \times 10^{-14} \text{ GeV}$$

$$\Delta a_Y = (-3.8 \pm 2.2) \times 10^{-14} \text{ GeV}$$

$$\text{Re}(\xi) = -0.022 \pm 0.033$$

$$\text{Im}(\xi) = 0.004 \pm 0.011$$

These branching fractions all scale with  $B(\bar{b} \rightarrow B_s^0)$ .

The branching fraction  $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{anything})$  is not a pure measurement since the measured product branching fraction  $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{anything})$  was used to determine  $B(\bar{b} \rightarrow B_s^0)$ , as described in the note on “ $B^0$ - $\bar{B}^0$  Mixing”

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

 **$\psi(3770)$** 

$$J^G(J^{PC}) = 0^-(1^{--})$$

Mass  $m = 3773.13 \pm 0.35$  MeV (S = 1.1)

Full width  $\Gamma = 27.2 \pm 1.0$  MeV

$\Gamma_{ee} = 0.262 \pm 0.018$  keV (S = 1.4)

In addition to the dominant decay mode to  $D\bar{D}$ ,  $\psi(3770)$  was found to decay into the final states containing the  $J/\psi$  (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to  $\phi\eta$  only (ADAMS 06).

---

**Z<sub>c</sub>(3900)**

$I^G(J^{PC}) = 1^+(1^{+-})$

Mass  $m = 3886.6 \pm 2.4$  MeV (S = 1.6)

Full width  $\Gamma = 28.2 \pm 2.6$  MeV

---

**X(3915)**

$I^G(J^{PC}) = 0^+(0 \text{ or } 2^{++})$

Mass  $m = 3918.4 \pm 1.9$  MeV

Full width  $\Gamma = 20 \pm 5$  MeV (S = 1.1)

---

**$\chi_{c2}(3930)$**

$I^G(J^{PC}) = 0^+(2^{++})$

Mass  $m = 3927.2 \pm 2.6$  MeV

Full width  $\Gamma = 24 \pm 6$  MeV

---

**X(4020)**

$I^G(J^{PC}) = 1^+ (?^? -)$

Mass  $m = 4024.1 \pm 1.9$  MeV

Full width  $\Gamma = 13 \pm 5$  MeV (S = 1.7)

---

**$\psi(4040)$  [xxaa]**

$I^G(J^{PC}) = 0^-(1^{--})$

Mass  $m = 4039 \pm 1$  MeV

Full width  $\Gamma = 80 \pm 10$  MeV

$\Gamma_{ee} = 0.86 \pm 0.07$  keV

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle's central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

## NOTES

In this Summary Table:

When a quantity has “( $S = \dots$ )” to its right, the error on the quantity has been enlarged by the “scale factor”  $S$ , defined as  $S = \sqrt{\chi^2/(N-1)}$ , where  $N$  is the number of measurements used in calculating the quantity.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] See the “Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors” in the  $\pi^\pm$  Particle Listings in the Full Review of Particle Physics for definitions and details.
- [b] Measurements of  $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$  always include decays with  $\gamma$ 's, and measurements of  $\Gamma(e^+\nu_e\gamma)$  and  $\Gamma(\mu^+\nu_\mu\gamma)$  never include low-energy  $\gamma$ 's. Therefore, since no clean separation is possible, we consider the modes with  $\gamma$ 's to be subreactions of the modes without them, and let  $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$ .
- [c] See the  $\pi^\pm$  Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement; low-energy  $\gamma$ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order  $10^{-13}$ ; see the  $\pi^0$  Particle Listings in the Full Review of Particle Physics.
- [f]  $C$  parity forbids this to occur as a single-photon process.
- [g] See the “Note on scalar mesons” in the  $f_0(500)$  Particle Listings in the Full Review of Particle Physics. The interpretation of this entry as a particle is controversial.
- [h] See the “Note on  $\rho(770)$ ” in the  $\rho(770)$  Particle Listings in the Full Review of Particle Physics.
- [i] The  $\omega\rho$  interference is then due to  $\omega\rho$  mixing only, and is expected to be small. If  $e\mu$  universality holds,  $\Gamma(\rho^0 \rightarrow \mu^+\mu^-) = \Gamma(\rho^0 \rightarrow e^+e^-) \times 0.99785$ .
- [j] See the “Note on scalar mesons” in the  $f_0(500)$  Particle Listings in the Full Review of Particle Physics.
- [k] See the “Note on  $a_1(1260)$ ” in the  $a_1(1260)$  Particle Listings in PDG 06, Journal of Physics **G33** 1 (2006).
- [l] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings in the Full Review of Particle Physics for details.
- [n] See the “Note on non- $q\bar{q}$  mesons” in the Particle Listings in PDG 06, Journal of Physics **G33** 1 (2006).

[o] See the “Note on the  $\eta(1405)$ ” in the  $\eta(1405)$  Particle Listings in the Full Review of Particle Physics.

[p] See the “Note on the  $f_1(1420)$ ” in the  $\eta(1405)$  Particle Listings in the Full Review of Particle Physics.

[q] See also the  $\omega(1650)$  Particle Listings.

[r] See the “Note on the  $\rho(1450)$  and the  $\rho(1700)$ ” in the  $\rho(1700)$  Particle Listings in the Full Review of Particle Physics.

[s] See also the  $\omega(1420)$  Particle Listings.

[t] See the “Note on  $f_0(1710)$ ” in the  $f_0(1710)$  Particle Listings in 2004 edition of Review of Particle Physics.

[u] See the note in the  $K^\pm$  Particle Listings in the Full Review of Particle Physics.

[v] Neglecting photon channels. See, e.g., A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).

[x] The definition of the slope parameters of the  $K \rightarrow 3\pi$  Dalitz plot is as follows (see also “Note on Dalitz Plot Parameters for  $K \rightarrow 3\pi$  Decays” in the  $K^\pm$  Particle Listings in the Full Review of Particle Physics):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \dots$$

[y] For more details and definitions of parameters see Particle Listings in the Full Review of Particle Physics.

[z] See the  $K^\pm$  Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.

[aa] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[bb] Structure-dependent part.

[cc] Direct-emission branching fraction.

[dd] Violates angular-momentum conservation.

[ee] Derived from measured values of  $\phi_{+-}$ ,  $\phi_{00}$ ,  $|\eta|$ ,  $|m_{K_L^0} - m_{K_S^0}|$ , and  $\tau_{K_S^0}$ , as described in the introduction to “Tests of Conservation Laws.”

[ff] The  $CP$ -violation parameters are defined as follows (see also “Note on  $CP$  Violation in  $K_S \rightarrow 3\pi$ ” and “Note on  $CP$  Violation in  $K_L^0$  Decay” in the Particle Listings in the Full Review of Particle Physics):

$$\eta_{+-} = |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \rightarrow \pi^+ \pi^-)}{A(K_S^0 \rightarrow \pi^+ \pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \rightarrow \pi^0 \pi^0)}{A(K_S^0 \rightarrow \pi^0 \pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)},$$

$$|\text{Im}(\eta_{+-0})|^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)^{CP \text{ viol.}}}{\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)},$$

$$|\text{Im}(\eta_{000})|^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)}{\Gamma(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0)}.$$

where for the last two relations  $CPT$  is assumed valid, i.e.,  $\text{Re}(\eta_{+-0}) \simeq 0$  and  $\text{Re}(\eta_{000}) \simeq 0$ .

[gg] See the  $K_S^0$  Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.

- [hh] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [ii]  $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$  to a very good approximation provided the phases satisfy  $CPT$  invariance.
- [jj] This mode includes gammas from inner bremsstrahlung but not the direct emission mode  $K_L^0 \rightarrow \pi^+ \pi^- \gamma$ (DE).
- [kk] See the  $K_L^0$  Particle Listings in the Full Review of Particle Physics for the energy limits used in this measurement.
- [ll] Allowed by higher-order electroweak interactions.
- [nn] Violates  $CP$  in leading order. Test of direct  $CP$  violation since the indirect  $CP$ -violating and  $CP$ -conserving contributions are expected to be suppressed.
- [oo] See the “Note on  $f_0(1370)$ ” in the  $f_0(1370)$  Particle Listings in the Full Review of Particle Physics and in the 1994 edition.
- [pp] See the note in the  $L(1770)$  Particle Listings in Reviews of Modern Physics **56** S1 (1984), p. S200. See also the “Note on  $K_2(1770)$  and the  $K_2(1820)$ ” in the  $K_2(1770)$  Particle Listings in the Full Review of Particle Physics.
- [qq] See the “Note on  $K_2(1770)$  and the  $K_2(1820)$ ” in the  $K_2(1770)$  Particle Listings in the Full Review of Particle Physics.
- [rr] This result applies to  $Z^0 \rightarrow c\bar{c}$  decays only. Here  $\ell^+$  is an average (not a sum) of  $e^+$  and  $\mu^+$  decays.
- [ss] See the Particle Listings for the (complicated) definition of this quantity.
- [tt] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings in the Full Review of Particle Physics.
- [uu] These subfractions of the  $K^- 2\pi^+$  mode are uncertain: see the Particle Listings.
- [vv] Submodes of the  $D^+ \rightarrow K^- 2\pi^+ \pi^0$  and  $K_S^0 2\pi^+ \pi^-$  modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [xx] The unseen decay modes of the resonances are included.
- [yy] This is not a test for the  $\Delta C=1$  weak neutral current, but leads to the  $\pi^+ \ell^+ \ell^-$  final state.
- [zz] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.
- [aaa] In the 2010 Review, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.
- [bbb] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.
- [ccc] This is the sum of our  $K^- 2\pi^+ \pi^-$ ,  $K^- 2\pi^+ \pi^- \pi^0$ ,  $K^0 2\pi^+ 2\pi^-$ ,  $K^+ 2K^- \pi^+$ ,  $2\pi^+ 2\pi^-$ ,  $2\pi^+ 2\pi^- \pi^0$ ,  $K^+ K^- \pi^+ \pi^-$ , and  $K^+ K^- \pi^+ \pi^- \pi^0$ , branching fractions.
- [ddd] This is the sum of our  $K^- 3\pi^+ 2\pi^-$  and  $3\pi^+ 3\pi^-$  branching fractions.
- [eee] The branching fractions for the  $K^- e^+ \nu_e$ ,  $K^*(892)^- e^+ \nu_e$ ,  $\pi^- e^+ \nu_e$ , and  $\rho^- e^+ \nu_e$  modes add up to  $6.19 \pm 0.17\%$ .
- [fff] This is a doubly Cabibbo-suppressed mode.

- [ggg] Submodes of the  $D^0 \rightarrow K_S^0 \pi^+ \pi^- \pi^0$  mode with a  $K^*$  and/or  $\rho$  were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [hhh] This branching fraction includes all the decay modes of the resonance in the final state.
- [iii] This limit is for either  $D^0$  or  $\bar{D}^0$  to  $p e^-$ .
- [jjj] This limit is for either  $D^0$  or  $\bar{D}^0$  to  $\bar{p} e^+$ .
- [kkk] This is the purely  $e^+$  semileptonic branching fraction: the  $e^+$  fraction from  $\tau^+$  decays has been subtracted off. The sum of our (non- $\tau$ )  $e^+$  exclusive fractions — an  $e^+ \nu_e$  with an  $\eta$ ,  $\eta'$ ,  $\phi$ ,  $K^0$ , or  $K^{*0}$  — is  $5.99 \pm 0.31\%$ .
- [lll] This fraction includes  $\eta$  from  $\eta'$  decays.
- [nnn] The sum of our exclusive  $\eta'$  fractions —  $\eta' e^+ \nu_e$ ,  $\eta' \mu^+ \nu_\mu$ ,  $\eta' \pi^+$ ,  $\eta' \rho^+$ , and  $\eta' K^+$  — is  $11.8 \pm 1.6\%$ .
- [ooo] This branching fraction includes all the decay modes of the final-state resonance.
- [ppp] A test for  $u\bar{u}$  or  $d\bar{d}$  content in the  $D_s^+$ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and  $\omega - \phi$  mixing is an unlikely explanation for any fraction above about  $2 \times 10^{-4}$ .
- [qqq] We decouple the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+$ ,  $\phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.
- [rrr] This is the average of a model-independent and a  $K$ -matrix parametrization of the  $\pi^+ \pi^-$   $S$ -wave and is a sum over several  $f_0$  mesons.
- [sss] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.
- [ttt] An  $CP(\pm 1)$  indicates the  $CP=+1$  and  $CP=-1$  eigenstates of the  $D^0$ - $\bar{D}^0$  system.
- [uuu]  $D$  denotes  $D^0$  or  $\bar{D}^0$ .
- [vvv]  $D_{CP+}^{*0}$  decays into  $D^0 \pi^0$  with the  $D^0$  reconstructed in  $CP$ -even eigenstates  $K^+ K^-$  and  $\pi^+ \pi^-$ .
- [xxx]  $\bar{D}^{**}$  represents an excited state with mass  $2.2 < M < 2.8$  GeV/c $^2$ .
- [yyy]  $\chi_{c1}(3872)^+$  is a hypothetical charged partner of the  $\chi_{c1}(3872)$ .
- [zzz]  $\Theta(1710)^{++}$  is a possible narrow pentaquark state and  $G(2220)$  is a possible glueball resonance.
- [aaaa]  $(\bar{\Lambda}_c^- p)_s$  denotes a low-mass enhancement near 3.35 GeV/c $^2$ .
- [bbaa] Stands for the possible candidates of  $K^*(1410)$ ,  $K_0^*(1430)$  and  $K_2^*(1430)$ .
- [ccaa]  $B^0$  and  $B_s^0$  contributions not separated. Limit is on weighted average of the two decay rates.
- [ddaa] This decay refers to the coherent sum of resonant and nonresonant  $J^P = 0^+$   $K\pi$  components with  $1.60 < m_{K\pi} < 2.15$  GeV/c $^2$ .
- [eeaa]  $X(214)$  is a hypothetical particle of mass 214 MeV/c $^2$  reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)
- [ffaa]  $\Theta(1540)^+$  denotes a possible narrow pentaquark state.

- [*ggaa*] Here  $S$  and  $P$  are the hypothetical scalar and pseudoscalar particles with masses of  $2.5 \text{ GeV}/c^2$  and  $214.3 \text{ MeV}/c^2$ , respectively.
- [*hhaa*] These values are model dependent.
- [*iiaa*] Here “anything” means at least one particle observed.
- [*jjaa*] This is a  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell)$  value.
- [*kkaa*]  $D^{**}$  stands for the sum of the  $D(1^1P_1)$ ,  $D(1^3P_0)$ ,  $D(1^3P_1)$ ,  $D(1^3P_2)$ ,  $D(2^1S_0)$ , and  $D(2^1S_1)$  resonances.
- [*llaa*]  $D^{(*)}\overline{D}^{(*)}$  stands for the sum of  $D^*\overline{D}^*$ ,  $D^*\overline{D}$ ,  $D\overline{D}^*$ , and  $D\overline{D}$ .
- [*nnaa*]  $X(3915)$  denotes a near-threshold enhancement in the  $\omega J/\psi$  mass spectrum.
- [*ooaa*] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [*ppaa*]  $D_j$  represents an unresolved mixture of pseudoscalar and tensor  $D^{**}$  ( $P$ -wave) states.
- [*qqaa*] Not a pure measurement. See note at head of  $B_s^0$  Decay Modes.
- [*rraa*] For  $E_\gamma > 100 \text{ MeV}$ .
- [*ssaa*] Includes  $p\overline{p}\pi^+\pi^-\gamma$  and excludes  $p\overline{p}\eta$ ,  $p\overline{p}\omega$ ,  $p\overline{p}\eta'$ .
- [*ttaa*] For a narrow state  $A$  with mass less than  $960 \text{ MeV}$ .
- [*uuaa*] For a narrow scalar or pseudoscalar  $A^0$  with mass  $0.21\text{--}3.0 \text{ GeV}$ .
- [*vva*a] For a narrow resonance in the range  $2.2 < M(X) < 2.8 \text{ GeV}$ .
- [*xxaa*]  $J^{PC}$  known by production in  $e^+e^-$  via single photon annihilation.  
 $J^G$  is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.
- [*yyaa*]  $2m_\tau < M(\tau^+\tau^-) < 9.2 \text{ GeV}$
- [*zzaa*]  $2 \text{ GeV} < m_{K^+K^-} < 3 \text{ GeV}$
- [*aabb*]  $X = \text{scalar}$  with  $m < 8.0 \text{ GeV}$
- [*bbbb*]  $X\overline{X} = \text{vectors}$  with  $m < 3.1 \text{ GeV}$
- [*ccbb*]  $X$  and  $\overline{X} = \text{zero spin}$  with  $m < 4.5 \text{ GeV}$
- [*ddbb*]  $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [*eebb*]  $201 \text{ MeV} < M(\mu^+\mu^-) < 3565 \text{ MeV}$
- [*ffbb*]  $0.5 \text{ GeV} < m_X < 9.0 \text{ GeV}$ , where  $m_X$  is the invariant mass of the hadronic final state.
- [*ggbb*] Spectroscopic labeling for these states is theoretical, pending experimental information.
- [*hhbb*]  $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [*iibb*]  $1.5 \text{ GeV} < m_X < 5.0 \text{ GeV}$
- [*jjbb*] For  $m_{\tau^+\tau^-}$  in the ranges  $4.03\text{--}9.52$  and  $9.61\text{--}10.10 \text{ GeV}$ .

See Particle Listings for 1 decay modes that have been seen / not seen.

 **$\Lambda_c(2595)^+$** 

$$I(J^P) = 0(\frac{1}{2}^-)$$

The spin-parity follows from the fact that  $\Sigma_c(2455)\pi$  decays, with little available phase space, are dominant. This assumes that  $J^P = 1/2^+$  for the  $\Sigma_c(2455)$ .

Mass  $m = 2592.25 \pm 0.28$  MeV

$m - m_{\Lambda_c^+} = 305.79 \pm 0.24$  MeV

Full width  $\Gamma = 2.6 \pm 0.6$  MeV

$\Lambda_c^+ \pi \pi$  and its submode  $\Sigma_c(2455)\pi$  — the latter just barely — are the only strong decays allowed to an excited  $\Lambda_c^+$  having this mass; and the submode seems to dominate.

<b><math>\Lambda_c(2595)^+</math> DECAY MODES</b>	Fraction ( $\Gamma_i/\Gamma$ )	$p$ (MeV/c)
$\Lambda_c^+ \pi^+ \pi^-$	[t] —	117
$\Sigma_c(2455)^{++} \pi^-$	$24 \pm 7$ %	†
$\Sigma_c(2455)^0 \pi^+$	$24 \pm 7$ %	†
$\Lambda_c^+ \pi^+ \pi^-$ 3-body	$18 \pm 10$ %	117

See Particle Listings for 2 decay modes that have been seen / not seen.

 **$\Lambda_c(2625)^+$** 

$$I(J^P) = 0(\frac{3}{2}^-)$$

$J^P$  has not been measured;  $\frac{3}{2}^-$  is the quark-model prediction.

Mass  $m = 2628.11 \pm 0.19$  MeV (S = 1.1)

$m - m_{\Lambda_c^+} = 341.65 \pm 0.13$  MeV (S = 1.1)

Full width  $\Gamma < 0.97$  MeV, CL = 90%

$\Lambda_c^+ \pi\pi$  and its submode  $\Sigma(2455)\pi$  are the only strong decays allowed to an excited  $\Lambda_c^+$  having this mass.

$\Lambda_c(2625)^+$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)

 **$b$ -baryon ADMIXTURE ( $\Lambda_b, \Xi_b, \Sigma_b, \Omega_b$ )**

These branching fractions are actually an average over weakly decaying  $b$ -baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the  $b$ -baryon production fraction  $B(b \rightarrow b\text{-baryon})$ .

The branching fractions  $B(b\text{-baryon} \rightarrow \Lambda \ell^- \bar{\nu}_\ell \text{anything})$  and  $B(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell \text{anything})$  are not pure measurements because the underlying measured products of these with  $B(b \rightarrow b\text{-baryon})$  were used to determine  $B(b \rightarrow b\text{-baryon})$ , as described in the note "Production and Decay of  $b$ -Flavored Hadrons."

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

 **$b$ -baryon ADMIXTURE DECAY MODES****( $\Lambda_b, \Xi_b, \Sigma_b, \Omega_b$ )**

$$\text{Fraction } (\Gamma_i/\Gamma)$$

$\Lambda \text{anything}$	$(37 \pm 7) \%$	-
$\Xi^- \ell^- \bar{\nu}_\ell \text{anything}$	$(6.2 \pm 1.6) \times 10^{-3}$	-

## NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the  $N$  and  $\Delta$  resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor"  $S$ , defined as  $S = \sqrt{\chi^2/(N - 1)}$ , where  $N$  is the number of measurements used in calculating the quantity.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating  $p$ .

- [a] The masses of the  $p$  and  $n$  are most precisely known in u (unified atomic mass units). The conversion factor to MeV,  $1\text{ u} = 931.494061(21)\text{ MeV}$ , is less well known than are the masses in u.
- [b] The  $|m_p - m_{\bar{p}}|/m_p$  and  $|q_p + q_{\bar{p}}|/e$  are not independent, and both use the more precise measurement of  $|q_{\bar{p}}/m_{\bar{p}}|/(q_p/m_p)$ .
- [c] The limit is from neutrality-of-matter experiments; it assumes  $q_n = q_p + q_e$ . See also the charge of the neutron.
- [d] The  $\mu p$  and  $e p$  values for the charge radius are much too different to average them. The disagreement is not yet understood.
- [e] There is a lot of disagreement about the value of the proton magnetic charge radius. See the Listings.
- [f] The first limit is for  $p \rightarrow$  anything or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray  $\bar{p}$ 's is  $\tau_{\bar{p}} > 10^7$  yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives  $\tau_{\bar{p}}/B(\bar{p} \rightarrow e^- \gamma) > 7 \times 10^5$  yr.
- [g] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [h] Lee and Yang in 1956 proposed the existence of a mirror world in an attempt to restore global parity symmetry—thus a search for oscillations between the two worlds. Oscillations between the worlds would be maximal when the magnetic fields  $B$  and  $B'$  were equal. The limit for any  $B'$  in the range 0 to  $12.5\text{ }\mu\text{T}$  is  $>12\text{ s}$  (95% CL).
- [i] The parameters  $g_A$ ,  $g_V$ , and  $g_{WM}$  for semileptonic modes are defined by  $\overline{B}_f[\gamma_\lambda(g_V + g_A\gamma_5) + i(g_{WM}/m_{B_i})\sigma_{\lambda\nu} q^\nu]B_i$ , and  $\phi_{AV}$  is defined by  $g_A/g_V = |g_A/g_V|e^{i\phi_{AV}}$ . See the "Note on Baryon Decay Parameters" in the neutron Particle Listings in the Full Review of Particle Physics.
- [j] Time-reversal invariance requires this to be  $0^\circ$  or  $180^\circ$ .
- [k] This coefficient is zero if time invariance is not violated.
- [l] This limit is for  $\gamma$  energies between 0.4 and 782 keV.
- [n] The decay parameters  $\gamma$  and  $\Delta$  are calculated from  $\alpha$  and  $\phi$  using

$$\gamma = \sqrt{1-\alpha^2} \cos\phi, \quad \tan\Delta = -\frac{1}{\alpha} \sqrt{1-\alpha^2} \sin\phi.$$

See the “Note on Baryon Decay Parameters” in the neutron Particle Listings in the Full *Review of Particle Physics*.

- [o] See Particle Listings in the Full *Review of Particle Physics* for the pion momentum range used in this measurement.
- [p] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [q] A theoretical value using QED.
- [r] This branching fraction includes all the decay modes of the final-state resonance.
- [s] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [t] See AALTONEN 11H, Fig. 8, for the calculated ratio of  $\Lambda_c^+ \pi^0 \pi^0$  and  $\Lambda_c^+ \pi^+ \pi^-$  partial widths as a function of the  $\Lambda_c(2595)^+ - \Lambda_c^+$  mass difference. At our value of the mass difference, the ratio is about 4.
- [u]  $P_c^+$  is a pentaquark-charmonium state.
- [v] Not a pure measurement. See note at head of  $\Lambda_b^0$  Decay Modes.
- [x] Here  $h^-$  means  $\pi^-$  or  $K^-$ .

## SEARCHES not in other sections

### Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$$< 1.4 \times 10^{-16} \text{ cm}^{-2}\text{sr}^{-1}\text{s}^{-1} \quad \text{for } 1.1 \times 10^{-4} < \beta < 1$$

### Supersymmetric Particle Searches

All supersymmetric mass bounds here are model dependent.

The limits assume:

1)  $\tilde{\chi}_1^0$  is the lightest supersymmetric particle; 2)  $R$ -parity is conserved;

See the Particle Listings in the Full *Review of Particle Physics* for a Note giving details of supersymmetry.

$\tilde{\chi}_i^0$  — neutralinos (mixtures of  $\tilde{\gamma}$ ,  $\tilde{Z}^0$ , and  $\tilde{H}_i^0$ )

Mass  $m_{\tilde{\chi}_1^0} > 0$  GeV, CL = 95%

[general MSSM, non-universal gaugino masses]

Mass  $m_{\tilde{\chi}_1^0} > 46$  GeV, CL = 95%

[all  $\tan\beta$ , all  $m_0$ , all  $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$ ]

Mass  $m_{\tilde{\chi}_2^0} > 670$  GeV, CL = 95%

[ $3/4\ell + \cancel{E}_T$ , Tn2n3B,  $m_{\tilde{\chi}_1^0} < 200$ GeV]

Mass  $m_{\tilde{\chi}_3^0} > 670$  GeV, CL = 95%

[ $3/4\ell + \cancel{E}_T$ , Tn2n3B,  $m_{\tilde{\chi}_1^0} < 200$ GeV]

Mass  $m_{\tilde{\chi}_4^0} > 116$  GeV, CL = 95%

[ $1 < \tan\beta < 40$ , all  $m_0$ , all  $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$ ]

$\tilde{\chi}_i^\pm$  — charginos (mixtures of  $\tilde{W}^\pm$  and  $\tilde{H}_i^\pm$ )

Mass  $m_{\tilde{\chi}_1^\pm} > 94$  GeV, CL = 95%

[ $\tan\beta < 40$ ,  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 3$  GeV, all  $m_0$ ]

Mass  $m_{\tilde{\chi}_1^\pm} > 500$  GeV, CL = 95%

[ $2\ell^\pm + \cancel{E}_T$ , Tchi1chi1B,  $m_{\tilde{\chi}_1^0} = 0$  GeV]

$\tilde{\chi}^\pm$  — long-lived chargino

Mass  $m_{\tilde{\chi}^\pm} > 620$  GeV, CL = 95% [stable  $\tilde{\chi}^\pm$ ]

$\tilde{\nu}$  — sneutrino

Mass  $m > 41$  GeV, CL = 95% [model independent]

Mass  $m > 94$  GeV, CL = 95%

[CMSSM,  $1 \leq \tan\beta \leq 40$ ,  $m_{\tilde{e}_R} - m_{\tilde{\chi}_1^0} > 10$  GeV]

Mass  $m > 2300$  GeV, CL = 95%

[RPV,  $\tilde{\nu}_\tau \rightarrow e\mu$ ,  $\lambda'_{311} = 0.11$ ]

$\tilde{e}$  — scalar electron (selectron)

Mass  $m(\tilde{e}_L) > 107$  GeV, CL = 95% [all  $m_{\tilde{e}_L} - m_{\tilde{\chi}_1^0}$ ]

Mass  $m > 410$  GeV, CL = 95%

[RPV,  $\geq 4\ell^\pm, \tilde{\ell} \rightarrow l\tilde{\chi}_1^0, \tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$ ]

$\tilde{\mu}$  — scalar muon (smuon)

Mass  $m > 94$  GeV, CL = 95%

[CMSSM,  $1 \leq \tan\beta \leq 40$ ,  $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10$  GeV]

Mass  $m > 410$  GeV, CL = 95%

[RPV,  $\geq 4\ell^\pm, \tilde{\ell} \rightarrow l\tilde{\chi}_1^0, \tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$ ]

$\tilde{\tau}$  — scalar tau (stau)

Mass  $m > 81.9$  GeV, CL = 95%

[ $m_{\tilde{\tau}_R} - m_{\tilde{\chi}_1^0} > 15$  GeV, all  $\theta_\tau$ ,  $B(\tilde{\tau} \rightarrow \tau \tilde{\chi}_1^0) = 100\%$ ]

Mass  $m > 286$  GeV, CL = 95% [long-lived  $\tilde{\tau}$ ]

$\tilde{q}$  — squarks of the first two quark generations

Mass  $m > 1450$  GeV, CL = 95%

[CMSSM,  $\tan\beta = 30$ ,  $A_0 = -2\max(m_0, m_{1/2})$ ,  $\mu > 0$ ]

Mass  $m > 1550$  GeV, CL = 95%

[mass degenerate squarks]

Mass  $m > 1050$  GeV, CL = 95%

[single light squark bounds]

$\tilde{q}$  — long-lived squark

Mass  $m > 1000$ , CL = 95%

[ $\tilde{t}$ , charge-suppressed interaction model]

Mass  $m > 845$ , CL = 95% [ $\tilde{b}$ , stable, Regge model]

$\tilde{b}$  — scalar bottom (sbottom)

Mass  $m > 1230$  GeV, CL = 95%

[ $\text{jets} + \cancel{E}_T$ , Tbot1,  $m_{\tilde{\chi}_1^0} = 0$  GeV]

$\tilde{t}$  — scalar top (stop)

Mass  $m > 1120$  GeV, CL = 95%

[ $1\ell + \text{jets} + \cancel{E}_T$ , Tstop1,  $m_{\tilde{\chi}_1^0} = 0$  GeV]

$\tilde{g}$  — gluino

Mass  $m > 1860$  GeV, CL = 95%

[ $\geq 1$  jets +  $\cancel{E}_T$ , Tglu1A,  $m_{\tilde{\chi}_1^0} = 0$  GeV]

## Technicolor

The limits for technicolor (and top-color) particles are quite varied depending on assumptions. See the Technicolor section of the full *Review* (the data listings).

## Quark and Lepton Compositeness, Searches for

### Scale Limits $\Lambda$ for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L$$

(with  $g^2/4\pi$  set equal to 1), then we define  $\Lambda \equiv \Lambda_{LL}^\pm$ . For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(eeee)$	> 8.3 TeV, CL = 95%
$\Lambda_{LL}^-(eeee)$	> 10.3 TeV, CL = 95%
$\Lambda_{LL}^+(ee\mu\mu)$	> 8.5 TeV, CL = 95%
$\Lambda_{LL}^-(ee\mu\mu)$	> 9.5 TeV, CL = 95%
$\Lambda_{LL}^+(ee\tau\tau)$	> 7.9 TeV, CL = 95%
$\Lambda_{LL}^-(ee\tau\tau)$	> 7.2 TeV, CL = 95%
$\Lambda_{LL}^+(\ell\ell\ell\ell)$	> 9.1 TeV, CL = 95%
$\Lambda_{LL}^-(\ell\ell\ell\ell)$	> 10.3 TeV, CL = 95%
$\Lambda_{LL}^+(eeqq)$	> 24 TeV, CL = 95%
$\Lambda_{LL}^-(eeqq)$	> 37 TeV, CL = 95%
$\Lambda_{LL}^+(eeuu)$	> 23.3 TeV, CL = 95%
$\Lambda_{LL}^-(eeuu)$	> 12.5 TeV, CL = 95%
$\Lambda_{LL}^+(eedd)$	> 11.1 TeV, CL = 95%
$\Lambda_{LL}^-(eedd)$	> 26.4 TeV, CL = 95%
$\Lambda_{LL}^+(eecc)$	> 9.4 TeV, CL = 95%
$\Lambda_{LL}^-(eecc)$	> 5.6 TeV, CL = 95%
$\Lambda_{LL}^+(eebb)$	> 9.4 TeV, CL = 95%
$\Lambda_{LL}^-(eebb)$	> 10.2 TeV, CL = 95%
$\Lambda_{LL}^+(\mu\mu qq)$	> 20 TeV, CL = 95%
$\Lambda_{LL}^-(\mu\mu qq)$	> 30 TeV, CL = 95%
$\Lambda(\ell\nu\ell\nu)$	> 3.10 TeV, CL = 90%
$\Lambda(e\nu qq)$	> 2.81 TeV, CL = 95%
$\Lambda_{LL}^+(qqqq)$	> 13.1 none 17.4–29.5 TeV, CL = 95%
$\Lambda_{LL}^-(qqqq)$	> 21.8 TeV, CL = 95%
$\Lambda_{LL}^+(\nu\nu qq)$	> 5.0 TeV, CL = 95%
$\Lambda_{LL}^-(\nu\nu qq)$	> 5.4 TeV, CL = 95%

## Excited Leptons

The limits from  $\ell^{*+} \ell^{*-}$  do not depend on  $\lambda$  (where  $\lambda$  is the  $\ell\ell\ell^*$  transition coupling). The  $\lambda$ -dependent limits assume chiral coupling.

$e^{*\pm}$  — excited electron

Mass  $m > 103.2$  GeV, CL = 95% (from  $e^* e^*$ )

Mass  $m > 3.000 \times 10^3$  GeV, CL = 95% (from  $e e^*$ )

Mass  $m > 356$  GeV, CL = 95% (if  $\lambda_\gamma = 1$ )

$\mu^{*\pm}$  — excited muon

Mass  $m > 103.2$  GeV, CL = 95% (from  $\mu^* \mu^*$ )

Mass  $m > 3.000 \times 10^3$  GeV, CL = 95% (from  $\mu \mu^*$ )

$\tau^{*\pm}$  — excited tau

Mass  $m > 103.2$  GeV, CL = 95% (from  $\tau^* \tau^*$ )

Mass  $m > 2.500 \times 10^3$  GeV, CL = 95% (from  $\tau \tau^*$ )

$\nu^*$  — excited neutrino

Mass  $m > 1.600 \times 10^3$  GeV, CL = 95% (from  $\nu^* \nu^*$ )

Mass  $m > 213$  GeV, CL = 95% (from  $\nu^* X$ )

$q^*$  — excited quark

Mass  $m > 338$  GeV, CL = 95% (from  $q^* q^*$ )

Mass  $m > 6.000 \times 10^3$  GeV, CL = 95% (from  $q^* X$ )

## Color Sextet and Octet Particles

Color Sextet Quarks ( $q_6$ )

Mass  $m > 84$  GeV, CL = 95% (Stable  $q_6$ )

Color Octet Charged Leptons ( $\ell_8$ )

Mass  $m > 86$  GeV, CL = 95% (Stable  $\ell_8$ )

Color Octet Neutrinos ( $\nu_8$ )

Mass  $m > 110$  GeV, CL = 90% ( $\nu_8 \rightarrow \nu g$ )

## Extra Dimensions

Refer to the Extra Dimensions section of the full *Review* for a discussion of the model-dependence of these bounds, and further constraints.

### Constraints on the radius of the extra dimensions, for the case of two-flat dimensions of equal radii

$R < 30$   $\mu\text{m}$ , CL = 95% (direct tests of Newton's law)

$R < 10.9$   $\mu\text{m}$ , CL = 95% ( $pp \rightarrow j G$ )

$R < 0.16\text{--}916$  nm (astrophys.; limits depend on technique, assumptions)

### Constraints on the fundamental gravity scale

$M_{TT} > 8.4$  TeV, CL = 95% ( $pp \rightarrow$  dijet, angular distribution)

$M_c > 4.16$  TeV, CL = 95% ( $pp \rightarrow \ell\bar{\ell}$ )

### Constraints on the Kaluza-Klein graviton in warped extra dimensions

$M_G > 4.1$  TeV, CL = 95% ( $pp \rightarrow \gamma\gamma$ )

### Constraints on the Kaluza-Klein gluon in warped extra dimensions

$M_{g_{KK}} > 2.5$  TeV, CL = 95% ( $g_{KK} \rightarrow t\bar{t}$ )

**TESTS OF CONSERVATION LAWS**

Updated April 2018 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL) and E. Pianori (LBNL).

In the following text, we list the best limits from the Test of Conservation Laws table from the full *Review of Particle Physics*. Complete details are in that full *Review*. Limits in this text are for CL=90% unless otherwise specified. The Table is in two parts: “Discrete Space-Time Symmetries,” *i.e.*,  $C$ ,  $P$ ,  $T$ ,  $CP$ , and  $CPT$ ; and “Number Conservation Laws,” *i.e.*, lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the *Review*. A discussion of these tests follows.

 **$CPT$  INVARIANCE**

General principles of relativistic field theory require invariance under the combined transformation  $CPT$ . The simplest tests of  $CPT$  invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between  $K^0$  and  $\bar{K}^0$ . Any such difference contributes to the  $CP$ -violating parameter  $\epsilon$ .

 **$CP$  AND  $T$  INVARIANCE**

Given  $CPT$  invariance,  $CP$  violation and  $T$  violation are equivalent. The original evidence for CP violation came from the measurement of  $|\eta_{+-}| = |A(K_L^0 \rightarrow \pi^+\pi^-)/A(K_S^0 \rightarrow \pi^+\pi^-)| = (2.232 \pm 0.011) \times 10^{-3}$ . This could be explained in terms of  $K^0\bar{K}^0$  mixing, which also leads to the asymmetry  $[\Gamma(K_L^0 \rightarrow \pi^-e^+\nu) - \Gamma(K_L^0 \rightarrow \pi^+e^-\bar{\nu})]/[\text{sum}] = (0.334 \pm 0.007)\%$ . Evidence for  $CP$  violation in the kaon decay amplitude comes from the measurement of  $(1 - |\eta_{00}/\eta_{+-}|)/3 = Re(\epsilon'/\epsilon) = (1.66 \pm 0.23) \times 10^{-3}$ . In the Standard Model much larger  $CP$ -violating effects are expected. The first of these, which is associated with  $B\bar{B}$  mixing, is the parameter  $\sin(2\beta)$  now measured quite accurately to be  $0.679 \pm 0.020$ . A number of other  $CP$ -violating observables are being measured in  $B$  decays; direct evidence for  $CP$  violation in the  $B$  decay amplitude comes from the asymmetry  $[\Gamma(\bar{B}^0 \rightarrow K^-\pi^+) - \Gamma(B^0 \rightarrow K^+\pi^-)]/[\text{sum}] = -0.082 \pm 0.006$ . Direct tests of  $T$  violation are much more difficult; a measurement by CPLEAR of the difference between the oscillation probabilities of  $K^0$  to  $\bar{K}^0$  and  $\bar{K}^0$  to  $K^0$  is related to  $T$  violation [3]. A nonzero value of the electric dipole

moment of the neutron and electron requires both  $P$  and  $T$  violation. The current experimental results are  $< 3.0 \times 10^{-26} e\text{ cm}$  (neutron), and  $< 8.7 \times 10^{-29} e\text{ cm}$  (electron) at the 90% C.L. The BABAR experiment reported the first direct observation of  $T$  violation in the  $B$  system. The measured  $T$ -violating parameters in the time evolution of the neutral  $B$  mesons are  $\Delta S_T^+ = -1.37 \pm 0.15$  and  $\Delta S_T^- = 1.17 \pm 0.21$ , with a significance of  $14\sigma$  [4]. This observation of  $T$  violation, with exchange of initial and final states of the neutral  $B$ , was made possible in a  $B$ -factory using the Einstein-Podolsky-Rosen Entanglement of the two  $B$ 's produced in the decay of the  $\Upsilon(4S)$  and the two time-ordered decays of the  $B$ 's as filtering measurements of the meson state [5].

## CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number  $L_e$ , muon number  $L_\mu$ , and tau number  $L_\tau$ , except for the effect of neutrino mixing associated with neutrino masses. Searches for violations are of the following types:

- a)  $\Delta L = 2$  for one type of charged lepton.** The best limit comes from the search for neutrinoless double beta decay  $(Z, A) \rightarrow (Z + 2, A) + e^- + e^-$ . The best laboratory limit is  $t_{1/2} > 1.07 \times 10^{26} \text{ yr}$  (CL=90%) for  ${}^{136}\text{Xe}$  from the KamLAND-Zen experiment [6].
- b) Conversion of one charged-lepton type to another.** For purely leptonic processes, the best limits are on  $\mu \rightarrow e\gamma$  and  $\mu \rightarrow 3e$ , measured as  $\Gamma(\mu \rightarrow e\gamma)/\Gamma(\mu \rightarrow \text{all}) < 4.2 \times 10^{-13}$  and  $\Gamma(\mu \rightarrow 3e)/\Gamma(\mu \rightarrow \text{all}) < 1.0 \times 10^{-12}$ .
- c) Conversion of one type of charged lepton into another type of charged antilepton.** The case most studied is  $\mu^- + (Z, A) \rightarrow e^+ + (Z - 2, A)$ , the strongest limit being  $\Gamma(\mu^- \text{Ti} \rightarrow e^+ \text{Ca})/\Gamma(\mu^- \text{Ti} \rightarrow \text{all}) < 3.6 \times 10^{-11}$ .
- d) Neutrino oscillations.** It is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo-Kobayashi-Maskawa quark mixing. However, if the only source of lepton-number violation is the mixing of low-mass neutrinos then processes such as  $\mu \rightarrow e\gamma$  are expected to have extremely small

unobservable probabilities. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental studies.

## CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, *i.e.* the conversion of a quark of one flavor ( $d, u, s, c, b, t$ ) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section “Cabibbo-Kobayashi-Maskawa Mixing Matrix”). The way in which these conservation laws are violated is tested as follows:

**(a)  $\Delta S = \Delta Q$  rule.** In the strangeness-changing semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as  $\Gamma(\Sigma^+ \rightarrow ne^+\nu)/\Gamma(\Sigma^+ \rightarrow \text{all}) < 5 \times 10^{-6}$ , and from a detailed analysis of  $K_L \rightarrow \pi e\nu$ , which yields the parameter  $x$ , measured to be  $(\text{Re } x, \text{Im } x) = (-0.002 \pm 0.006, 0.0012 \pm 0.0021)$ . Corresponding rules are  $\Delta C = \Delta Q$  and  $\Delta B = \Delta Q$ .

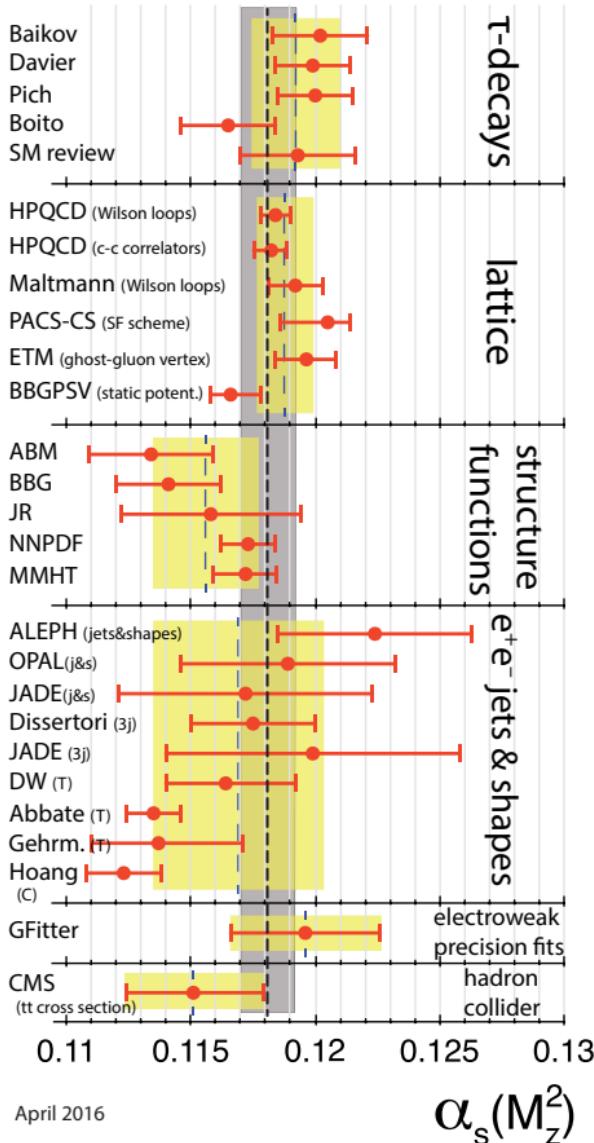

**(b) Change of flavor by two units.** In the Standard Model this occurs only in second-order weak interactions. The classic example is  $\Delta S = 2$  via  $K^0 - \bar{K}^0$  mixing. The  $\Delta B = 2$  transitions in the  $B^0$  and  $B_s^0$  systems via mixing are also well established. There is now strong evidence of  $\Delta C = 2$  transition in the charm sector, with the mass difference All results are consistent with the second-order calculations in the Standard Model.

**(c) Flavor-changing neutral currents.** In the Standard Model the neutral-current interactions do not change flavor. The low rate  $\Gamma(K_L \rightarrow \mu^+\mu^-)/\Gamma(K_L \rightarrow \text{all}) = (6.84 \pm 0.11) \times 10^{-9}$  puts limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from  $K^+ \rightarrow \pi^+\nu\bar{\nu}$ . The LHCb and CMS experiments have recently observed the FCNC decay of  $B_s^0 \rightarrow \mu^+\mu^-$ . The current world average value is  $\Gamma(B_s^0 \rightarrow \mu^+\mu^-)/\Gamma(B_s^0 \rightarrow \text{all}) = (2.7^{+0.6}_{-0.5}) \times 10^{-9}$ , which is consistent with the Standard Model expectation.

## 9. Quantum Chromodynamics

Revised September 2017 by S. Bethke (Max-Planck-Institute of Physics, Munich), G. Dissertori (ETH Zurich), and G.P. Salam (CERN).<sup>1</sup>

This update retains the 2016 summary of  $\alpha_s$  values, as few new results were available at the deadline for this Review. Those and further new results will be included in the next update.

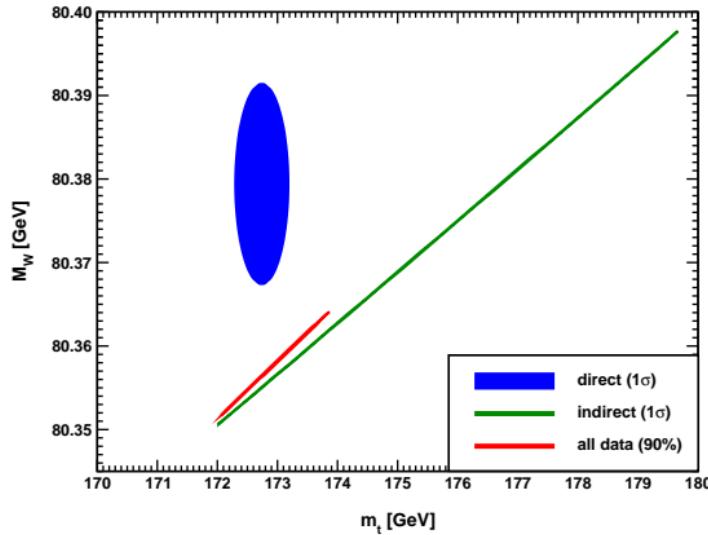

**Figure 9.2:** Summary of determinations of  $\alpha_s(M_Z^2)$  from the six sub-fields discussed in the text. The yellow (light shaded) bands and dashed lines indicate the pre-average values of each sub-field. The dotted line and grey (dark shaded) band represent the final world average value of  $\alpha_s(M_Z^2)$ .

## 10. Electroweak Model and Constraints on New Physics

Revised March 2018 by J. Erler (U. Mexico), A. Freitas (Pittsburgh U.).

The standard model of the electroweak interactions (SM) [1] is based on the gauge group  $SU(2) \times U(1)$ , with gauge bosons  $W_\mu^i$ ,  $i = 1, 2, 3$ , and  $B_\mu$  for the  $SU(2)$  and  $U(1)$  factors, respectively, and the corresponding gauge coupling constants  $g$  and  $g'$ .

**Figure 10.5:** One-standard-deviation (39.35%) region in  $M_W$  as a function of  $m_t$  for the direct and indirect data, and the 90% CL region ( $\Delta\chi^2 = 4.605$ ) allowed by all data.

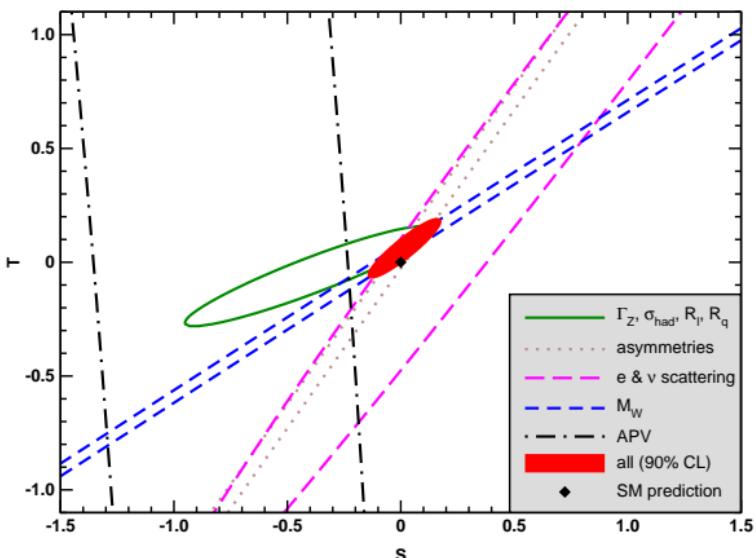

**Table 10.7:** Values of  $\hat{s}_Z^2$ ,  $s_W^2$ ,  $\alpha_s$ ,  $m_t$  and  $M_H$  [both in GeV] for various data sets. In the fit to the LHC (Tevatron) data the  $\alpha_s$  constraint is from the  $t\bar{t}$  production [204] (inclusive jet [205]) cross-section.

Data	$\hat{s}_Z^2$	$s_W^2$	$\alpha_s(M_Z)$	$m_t$	$M_H$
All data	0.23122(3)	0.22332(7)	0.1187(16)	$173.0 \pm 0.4$	125
All data except $M_H$	0.23107(9)	0.22310(19)	0.1190(16)	$172.8 \pm 0.5$	$90^{+17}_{-16}$
All data except $M_Z$	0.23113(6)	0.22336(8)	0.1187(16)	$172.8 \pm 0.5$	125
All data except $M_W$	0.23124(3)	0.22347(7)	0.1191(16)	$172.9 \pm 0.5$	125
All data except $m_t$	0.23112(6)	0.22304(21)	0.1191(16)	$176.4 \pm 1.8$	125
$M_H, M_Z, \Gamma_Z, m_t$	0.23125(7)	0.22351(13)	0.1209(45)	$172.7 \pm 0.5$	125
LHC	0.23110(11)	0.22332(12)	0.1143(24)	$172.4 \pm 0.5$	125
Tevatron + $M_Z$	0.23102(13)	0.22295(30)	0.1160(45)	$174.3 \pm 0.7$	$100^{+31}_{-26}$
LEP	0.23138(17)	0.22343(47)	0.1221(31)	$182 \pm 11$	$274^{+376}_{-152}$
SLD + $M_Z, \Gamma_Z, m_t$	0.23064(28)	0.22228(54)	0.1182(47)	$172.7 \pm 0.5$	$38^{+30}_{-21}$
$A_{FB}^{(b,c)}, M_Z, \Gamma_Z, m_t$	0.23190(29)	0.22503(69)	0.1278(50)	$172.7 \pm 0.5$	$348^{+187}_{-124}$
$M_{W,Z}, \Gamma_{W,Z}, m_t$	0.23103(12)	0.22302(25)	0.1192(42)	$172.7 \pm 0.5$	$84^{+22}_{-19}$
low energy + $M_{H,Z}$	0.23176(94)	0.2254(35)	0.1185(19)	$156 \pm 29$	125

**Table 10.8:** Values of the model-independent neutral-current parameters, compared with the SM predictions. There is a second  $g_{LV,LA}^{\nu e}$  solution, given approximately by  $g_{LV}^{\nu e} \leftrightarrow g_{LA}^{\nu e}$ , which is eliminated by  $e^+e^-$  data under the assumption that the neutral current is dominated by the exchange of a single  $Z$  boson. In the SM predictions, the parametric uncertainties from  $M_Z$ ,  $M_H$ ,  $m_t$ ,  $m_b$ ,  $m_c$ ,  $\hat{\alpha}(M_Z)$ , and  $\alpha_s$  are negligible.

Quantity	Experimental Value	Standard Model	Correlation	
$g_{LV}^{\nu e}$	$-0.040 \pm 0.015$	$-0.0398$		-0.05
$g_{LA}^{\nu e}$	$-0.507 \pm 0.014$	$-0.5063$		
$g_{AV}^{eu} + 2g_{AV}^{ed}$	$0.4914 \pm 0.0031$	$0.4950$	-0.88	0.19
$2g_{AV}^{eu} - g_{AV}^{ed}$	$-0.7148 \pm 0.0068$	$-0.7194$		-0.22
$2g_{VA}^{eu} - g_{VA}^{ed}$	$-0.13 \pm 0.06$	$-0.0954$		
$g_{VA}^{ee}$	$0.0190 \pm 0.0027$	$0.0226$		

The masses and decay properties of the electroweak bosons and low energy data can be used to search for and set limits on deviations from the SM.

**Figure 10.6:**  $1\sigma$  constraints (39.35% for the closed contours and 68% for the others) on  $S$  and  $T$  (for  $U = 0$ ) from various inputs combined with  $M_Z$ .  $S$  and  $T$  represent the contributions of new physics only. Data sets not involving  $M_W$  or  $\Gamma_W$  are insensitive to  $U$ . With the exception of the fit to all data, we fix  $\alpha_s = 0.1187$ . The black dot indicates the Standard Model values  $S = T = 0$ .

## 11. Status of Higgs Boson Physics

Revised August 2018 by M. Carena (Fermi National Accelerator Laboratory and the University of Chicago), C. Grojean (DESY, Hamburg, and Humboldt University, Berlin), M. Kado (Laboratoire de l'Accélérateur Linéaire, Orsay), and V. Sharma (University of California, San Diego).

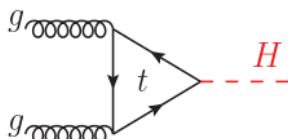

The discovery in 2012 by the ATLAS and the CMS collaborations of the Higgs boson was a major milestone as well as an extraordinary success of the LHC machine and the ATLAS and CMS experiments and an important step in the understanding of the mechanism that breaks the electroweak symmetry and generates of the masses of the known elementary particles. However, many theoretical questions remain unanswered and new conundrums about what lies behind the Higgs boson and beyond the Standard Model have come fore.

Since 2012 substantial progress has been made, yielding an increasingly precise profile of the properties of the Higgs boson, all being consistent with the Standard Model. And the Higgs boson has turned into a new tool to explore the manifestations of the SM and to probe the physics landscape beyond it.

The ATLAS and CMS experiments have made combined measurement of the mass of the Higgs boson in the diphoton and the four-lepton channels at per mille precision,  $m_H = 125.09 \pm 0.24$  GeV. The quantum numbers of the Higgs boson have been probed in greater detail and show an excellent consistency with the  $J^{PC} = 0^{++}$  hypothesis.

The coupling structure of the Higgs boson has been studied in a large number of channels, in the main production mechanisms at the LHC which are illustrated in the Figure. The Table summarises the ATLAS and CMS measurements and limits on the cross sections times branching fractions, normalised to their SM expectations in the main Higgs analysis channels. Further information on the couplings of the Higgs boson are also obtained from differential cross sections and searches for rare and exotic production and decay modes, including invisible decays.

All measurements are consistent with the SM predictions and provide stringent constraints on a large number of scenarios of new physics.

The review discusses in detail the latest developments in theories extending the SM to solve the fundamental questions raised by the existence of the Higgs boson.

## 12. CKM Quark-Mixing Matrix

Revised January 2018 by A. Ceccucci (CERN), Z. Ligeti (LBNL), and Y. Sakai (KEK).

Highlights from full review.

$$V_{\text{CKM}} \equiv V_L^u V_L^{d\dagger} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}. \quad (12.2)$$

This Cabibbo-Kobayashi-Maskawa (CKM) matrix [1,2] is a  $3 \times 3$  unitary matrix. It can be parameterized [3] by three mixing angles and the  $CP$ -violating KM phase [2].

Using the Wolfenstein parameterization with  $\lambda < 1$  we define [4–6]

$$\lambda = \frac{|V_{us}|}{\sqrt{|V_{ud}|^2 + |V_{us}|^2}}, \quad A\lambda^2 = \lambda \left| \frac{V_{cb}}{V_{us}} \right|, \\ V_{ub}^* = A\lambda^3(\bar{\rho} + i\bar{\eta}) = \frac{A\lambda^3(\bar{\rho} + i\bar{\eta})\sqrt{1 - A^2\lambda^4}}{\sqrt{1 - \lambda^2[1 - A^2\lambda^4(\bar{\rho} + i\bar{\eta})]}}. \quad (12.4)$$

These ensure that  $\bar{\rho} + i\bar{\eta} = -(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)$  is phase convention independent, and the CKM matrix written in terms of  $\lambda$ ,  $A$ ,  $\bar{\rho}$ , and  $\bar{\eta}$  is unitary to all orders in  $\lambda$ . To  $\mathcal{O}(\lambda^4)$

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (12.5)$$

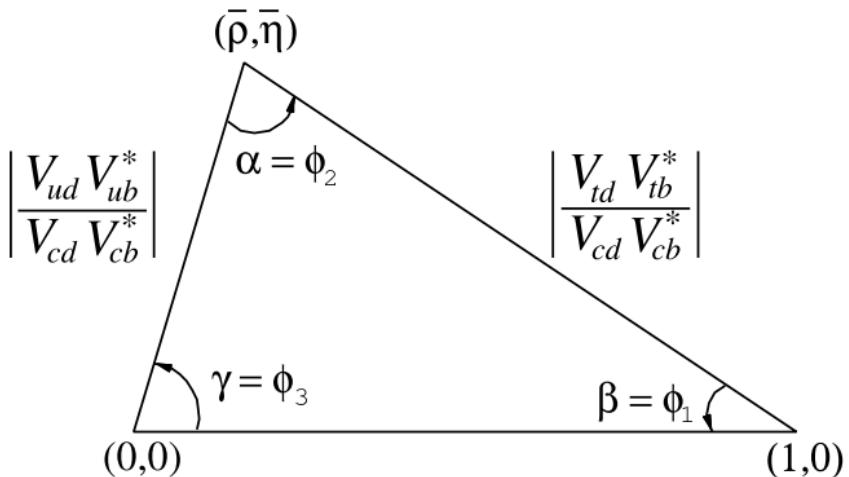

Figure 12.1: Sketch of the unitarity triangle.

The unitarity implies  $\sum_i V_{ij}V_{ik}^* = \delta_{jk}$  and  $\sum_j V_{ij}V_{kj}^* = \delta_{ik}$ . The six vanishing combinations can be represented as triangles in a complex plane. The areas of all triangles are the same and are half of the Jarlskog invariant,  $J$  [7], which is a phase-convention-independent measure of  $CP$  violation, defined by  $\text{Im}[V_{ij}V_{kl}V_{il}^*V_{kj}^*] = J \sum_{m,n} \varepsilon_{ikm}\varepsilon_{jln}$ .

The most commonly used unitarity triangle arises from

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0, \quad (12.6)$$

by dividing each side by the best-known one,  $V_{cd}V_{cb}^*$  (see Fig. 12.1).

Independently measured CKM elements and angles are

$$V_{\text{CKM}} = \begin{pmatrix} 0.97420 \pm 0.00021 & 0.2243 \pm 0.0005 & 0.00394 \pm 0.00036 \\ 0.218 \pm 0.004 & 0.997 \pm 0.017 & 0.0422 \pm 0.0008 \\ 0.0081 \pm 0.0005 & 0.0394 \pm 0.0023 & 1.019 \pm 0.025 \end{pmatrix},$$

$$\sin(2\beta) = 0.691 \pm 0.017, \quad \alpha = (84.5^{+5.9}_{-5.2})^\circ, \quad \gamma = (73.5^{+4.2}_{-5.1})^\circ.$$

Using those values we can check the unitarity of the CKM matrix:  $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9994 \pm 0.0005$  (1st row),  $|V_{cd}|^2 + |V_{cs}|^2 + |V_{cb}|^2 = 1.043 \pm 0.034$  (2nd row),  $|V_{ud}|^2 + |V_{cd}|^2 + |V_{td}|^2 = 0.9967 \pm 0.0018$  (1st column), and  $|V_{us}|^2 + |V_{cs}|^2 + |V_{ts}|^2 = 1.046 \pm 0.034$  (2nd column).

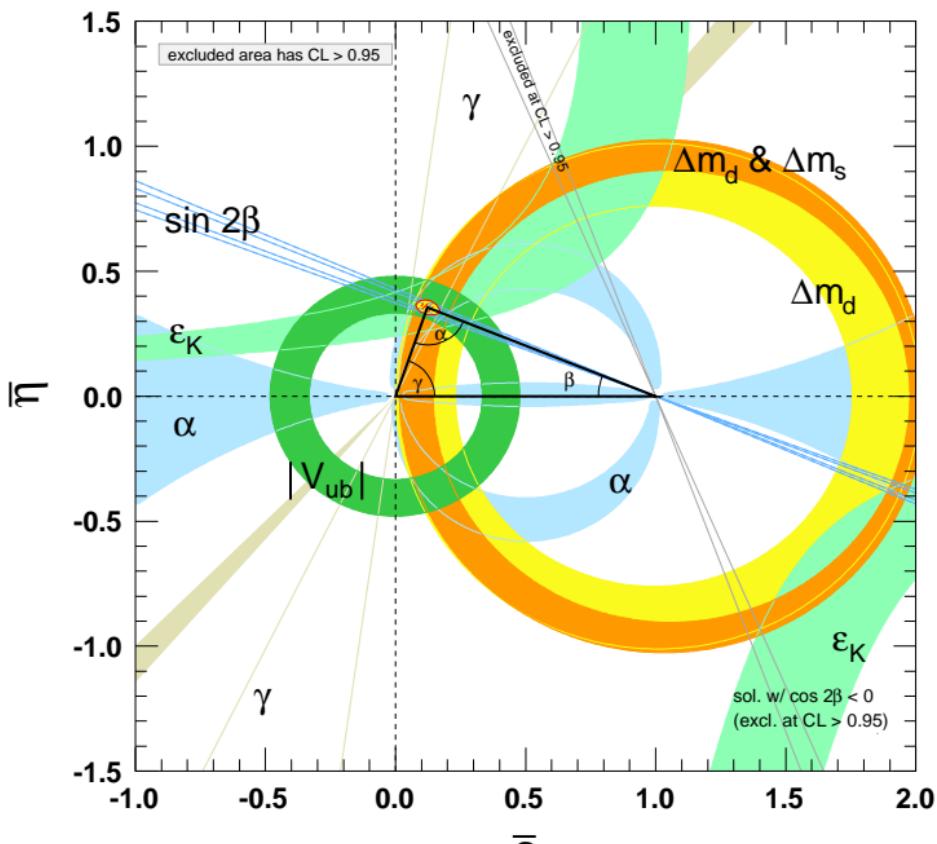

## 12.4. Global fit in the Standard Model

A global fit with three generation unitarity constraints gives

$$\lambda = 0.22453 \pm 0.00044, \quad A = 0.836 \pm 0.015, \\ \bar{\rho} = 0.122^{+0.018}_{-0.017}, \quad \bar{\eta} = 0.355^{+0.012}_{-0.011}, \quad (12.26)$$

$$V_{\text{CKM}} = \begin{pmatrix} 0.97446 \pm 0.00010 & 0.22452 \pm 0.00044 & 0.00365 \pm 0.00012 \\ 0.22438 \pm 0.00044 & 0.97359^{+0.00010}_{-0.00011} & 0.04214 \pm 0.00076 \\ 0.00896^{+0.00024}_{-0.00023} & 0.04133 \pm 0.00074 & 0.999105 \pm 0.000032 \end{pmatrix}, \quad (12.27)$$

and the Jarlskog invariant of  $J = (3.18 \pm 0.15) \times 10^{-5}$ .

**Figure 12.2:** Constraints on the  $\bar{\rho}, \bar{\eta}$  plane from various measurements and the global fit result. The shaded 95% CL regions all overlap consistently around the global fit region.

### 13. ***CP* Violation in the Quark Sector**

Revised August 2017 by T. Gershon (University of Warwick) and Y. Nir (Weizmann Institute).

Within the Standard Model, *CP* symmetry is broken by complex phases in the Yukawa couplings (that is, the couplings of the Higgs scalar to quarks). When all manipulations to remove unphysical phases in this model are exhausted, one finds that there is a single *CP*-violating parameter [17]. In the basis of mass eigenstates, this single phase appears in the  $3 \times 3$  unitary matrix that gives the  $W$ -boson couplings to an up-type antiquark and a down-type quark. The beautifully consistent and economical Standard-Model description of *CP* violation in terms of Yukawa couplings, known as the Kobayashi-Maskawa (KM) mechanism [17], agrees with all measurements to date. (Pending verification, we do not discuss here a few measurements which are in tension with the predictions.) Furthermore, one can fit the data allowing new physics contributions to loop processes to compete with, or even dominate over, the Standard Model amplitudes [18,19]. Such analyses provide model-independent proof that the KM phase is different from zero, and that the matrix of three-generation quark mixing is the dominant source of *CP* violation in meson decays.

The current level of experimental accuracy and the theoretical uncertainties involved in the interpretation of the various observations leave room, however, for additional subdominant sources of *CP* violation from new physics. Indeed, almost all extensions of the Standard Model imply that there are such additional sources. Moreover, *CP* violation is a necessary condition for baryogenesis, the process of dynamically generating the matter-antimatter asymmetry of the Universe [20]. Despite the phenomenological success of the KM mechanism, it fails (by several orders of magnitude) to accommodate the observed asymmetry [21]. This discrepancy strongly suggests that Nature provides additional sources of *CP* violation beyond the KM mechanism. The expectation of new sources motivates the large ongoing experimental effort to find deviations from the predictions of the KM mechanism.

Using the notation  $M^0$  to represent generically one of the  $K^0$ ,  $D^0$ ,  $B^0$  or  $B_s^0$  particles, we denote the state of an initially pure  $|M^0\rangle$  or  $|\overline{M}^0\rangle$  after an elapsed proper time  $t$  as  $|M_{\text{phys}}^0(t)\rangle$  or  $|\overline{M}_{\text{phys}}^0(t)\rangle$ , respectively. Defining  $x \equiv \Delta m/\Gamma$  and  $y \equiv \Delta\Gamma/(2\Gamma)$ , where  $\Delta m$  and  $\Delta\Gamma$  are the mass and width differences between the two eigenstates of the effective Hamiltonian,  $|M_L\rangle \propto p|M^0\rangle + q|\overline{M}^0\rangle$  and  $|M_H\rangle \propto p|M^0\rangle - q|\overline{M}^0\rangle$ , and  $\Gamma$  is their average width, one obtains the following time-dependent rates for decay to a final state  $f$ :

$$\begin{aligned} \frac{1}{e^{-\Gamma t} \mathcal{N}_f} d\Gamma[M_{\text{phys}}^0(t) \rightarrow f] / dt = \\ |A_f|^2 \left\{ \left(1 + |\lambda_f|^2\right) \cosh(y\Gamma t) + \left(1 - |\lambda_f|^2\right) \cos(x\Gamma t) \right. \\ \left. + 2\mathcal{R}e(\lambda_f) \sinh(y\Gamma t) - 2\mathcal{I}m(\lambda_f) \sin(x\Gamma t) \right\}, \\ \frac{1}{e^{-\Gamma t} \mathcal{N}_f} d\Gamma[\overline{M}_{\text{phys}}^0(t) \rightarrow f] / dt = \\ |(p/q)A_f|^2 \left\{ \left(1 + |\lambda_f|^2\right) \cosh(y\Gamma t) - \left(1 - |\lambda_f|^2\right) \cos(x\Gamma t) \right. \\ \left. - 2\mathcal{R}e(\lambda_f) \sinh(y\Gamma t) + 2\mathcal{I}m(\lambda_f) \sin(x\Gamma t) \right\}, \end{aligned}$$

$$+2\mathcal{R}e(\lambda_f)\sinh(y\Gamma t)+2\mathcal{I}m(\lambda_f)\sin(x\Gamma t)\} ,$$

where  $\mathcal{N}_f$  is a normalization factor and  $\lambda_f = (q/p)(\overline{A}_f/A_f)$  with  $A_f$  ( $\overline{A}_f$ ) the amplitude for the  $M^0$  ( $\overline{M}^0$ )  $\rightarrow f$  decay. Considering the case that  $f$  is a  $CP$  eigenstate, we distinguish three types of  $CP$ -violating effects that can occur in the quark sector:

- I.  $CP$  violation in decay, defined by  $|\overline{A}_f/A_f| \neq 1$ .
- II.  $CP$  violation in mixing, defined by  $|q/p| \neq 1$ .
- III.  $CP$  violation in interference between decays with and without mixing, defined by  $\arg(\lambda_f) \neq 0$ .

It is also common to refer to *indirect*  $CP$  violation effects, which are consistent with originating from a single  $CP$  violating phase in neutral meson mixing, and *direct*  $CP$  violation effects, which cannot be explained in this way.  $CP$  violation in mixing (type II) is indirect;  $CP$  violation in decay (type I) is direct.

Many  $CP$  violating observables have been studied by experiments. Here we summarise only a sample of the most important measurements, including some parameters defined using common notation for the asymmetry between  $\overline{B}_\text{phys}^0(t)$  and  $B_\text{phys}^0(t)$  time-dependent decay rates

$$\mathcal{A}_f(t) = S_f \sin(\Delta mt) - C_f \cos(\Delta mt),$$

where  $S_f \equiv 2\mathcal{I}m(\lambda_f)/\left(1 + |\lambda_f|^2\right)$ ,  $C_f \equiv \left(1 - |\lambda_f|^2\right)/\left(1 + |\lambda_f|^2\right)$ .

- Indirect  $CP$  violation in  $K \rightarrow \pi\pi$  and  $K \rightarrow \pi\ell\nu$  decays, given by

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}.$$

- Direct  $CP$  violation in  $K \rightarrow \pi\pi$  decays, given by

$$\mathcal{R}e(\epsilon'/\epsilon) = (1.65 \pm 0.26) \times 10^{-3}.$$

- As yet, there is no significant signal of any category of  $CP$  violation in the properties and decays of charm hadrons.
- $CP$  violation in the interference of mixing and decay in the tree-dominated  $b \rightarrow c\bar{c}s$  transitions, such as  $B^0 \rightarrow \psi K_S$ , given by

$$S_{\psi K^0} = +0.691 \pm 0.017.$$

Within the Standard Model, this result can be interpreted with low theoretical uncertainty as measurement of  $\sin(2\beta)$ , where  $\beta$  is an angle of the unitarity triangle.

- The  $CP$  violation parameters in the  $B^0 \rightarrow \pi^+\pi^-$  mode,

$$S_{\pi^+\pi^-} = -0.68 \pm 0.04, \quad C_{\pi^+\pi^-} = -0.27 \pm 0.04.$$

Together with measurements of other  $B \rightarrow \pi\pi$  and similar decays, these result can be used to obtain constraints on the angle  $\alpha$  of the unitarity triangle.

- Direct  $CP$  violation in  $B^+ \rightarrow DK^+$  decays, where  $D_+$  and  $D_{K-\pi^+}$  represent that the  $D$  meson is reconstructed in a  $CP$ -even and the suppressed  $K^-\pi^+$  final state respectively,

$$\mathcal{A}_{B^+ \rightarrow D_+ K^+} = +0.129 \pm 0.012, \quad \mathcal{A}_{B^+ \rightarrow D_{K-\pi^+} K^+} = -0.41 \pm 0.06.$$

Together with measurements of other  $B \rightarrow DK$  and similar decays, these result can be used to obtain constraints on the angle  $\gamma$  of the unitarity triangle.

## 14. Neutrino Masses, Mixing, and Oscillations

Updated November 2017 by K. Nakamura (Kavli IPMU (WPI), U. Tokyo, KEK), and S.T. Petcov (SISSA/INFN Trieste, Kavli IPMU (WPI), U. Tokyo, Bulgarian Academy of Sciences).

Highlights from full review.

All existing compelling data on neutrino oscillations can be described assuming 3-flavour neutrino mixing in vacuum. The (left-handed) fields of the flavour neutrinos  $\nu_e$ ,  $\nu_\mu$  and  $\nu_\tau$  in the expression for the weak charged lepton current in the CC weak interaction Lagrangian, are linear combinations of the LH components of the fields of three massive neutrinos  $\nu_j$ :

$$\begin{aligned} \mathcal{L}_{\text{CC}} = & -\frac{g}{\sqrt{2}} \sum_{l=e,\mu,\tau} \overline{l_L}(x) \gamma_\alpha l_L(x) W^{\alpha\dagger}(x) + h.c., \\ \nu_{lL}(x) = & \sum_{j=1}^3 U_{lj} \nu_{jL}(x), \end{aligned} \quad (14.5)$$

where  $U$  is the  $3 \times 3$  unitary neutrino mixing matrix [4,5]. The mixing matrix  $U$  can be parameterized by 3 angles, and, depending on whether the massive neutrinos  $\nu_j$  are Dirac or Majorana particles, by 1 or 3 CP violation phases [54,55]:

$$U = \begin{bmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{bmatrix} \times \text{diag}(1, e^{i\frac{\alpha_{21}}{2}}, e^{i\frac{\alpha_{31}}{2}}). \quad (14.6)$$

where  $c_{ij} = \cos \theta_{ij}$ ,  $s_{ij} = \sin \theta_{ij}$ , the angles  $\theta_{ij} = [0, \pi/2]$ ,  $\delta = [0, 2\pi)$  is the Dirac CP violation phase and  $\alpha_{21}$ ,  $\alpha_{31}$  are two Majorana CP violation (CPV) phases. Thus, in the case of massive Dirac neutrinos, the neutrino mixing matrix  $U$  is similar, in what concerns the number of mixing angles and CPV phases, to the CKM quark mixing matrix.

As we see, the fundamental parameters characterizing the 3-neutrino mixing are: i) the 3 angles  $\theta_{12}$ ,  $\theta_{23}$ ,  $\theta_{13}$ , ii) depending on the nature of massive neutrinos  $\nu_j$  - 1 Dirac ( $\delta$ ), or 1 Dirac + 2 Majorana ( $\delta, \alpha_{21}, \alpha_{31}$ ), CPV phases, and iii) the 3 neutrino masses,  $m_1$ ,  $m_2$ ,  $m_3$ .

The neutrino oscillation probabilities depend in general, on the neutrino energy,  $E$ , the source-detector distance  $L$ , on the elements of  $U$  and, for relativistic neutrinos used in all neutrino experiments performed so far, on  $\Delta m_{ij}^2 \equiv (m_i^2 - m_j^2)$ ,  $i \neq j$ . In the case of 3-neutrino mixing there are only two independent neutrino mass squared differences, say  $\Delta m_{21}^2 \neq 0$  and  $\Delta m_{31}^2 \neq 0$ . The numbering of massive neutrinos  $\nu_j$  is arbitrary. It proves convenient from the point of view of relating the mixing angles  $\theta_{12}$ ,  $\theta_{23}$  and  $\theta_{13}$  to observables, to identify  $|\Delta m_{21}^2|$  with the smaller of the two neutrino mass squared differences, which, as it follows from the data, is responsible for the solar  $\nu_e$  and, the observed by KamLAND, reactor  $\bar{\nu}_e$  oscillations.

The existing data do not allow one to determine the sign of  $\Delta m_{31(32)}^2$ . In the case of 3-neutrino mixing, the two possible signs of  $\Delta m_{31(32)}^2$  correspond to two types of neutrino mass spectrum.

For the neutrino oscillation parameters values, see the Summary Table section in the Particle Listings.

## Future progress

After the spectacular experimental progress made in the studies of neutrino oscillations, further understanding of the pattern of neutrino masses and neutrino mixing, of their origins and of the status of CP symmetry in the lepton sector requires an extensive and challenging program of research. The main goals of such a research program include:

- Determining the nature - Dirac or Majorana, of massive neutrinos  $\nu_j$ . This is of fundamental importance for making progress in our understanding of the origin of neutrino masses and mixing and of the symmetries governing the lepton sector of particle interactions.
- Determination of the sign of  $\Delta m_{31}^2$  (or  $\Delta m_{32}^2$ ), *i.e.*, the “neutrino mass ordering”, or of the type of spectrum neutrino masses obey.
- Determining, or obtaining significant constraints on, the absolute scale of neutrino masses. This, in particular, would help obtain information about the detailed structure (hierarchical, quasidegenerate, etc.) of the neutrino mass spectrum.
- Determining the status of CP symmetry in the lepton sector.
- High precision measurement of  $\theta_{13}$ ,  $\Delta m_{21}^2$ ,  $\theta_{12}$ ,  $|\Delta m_{31}^2|$  and  $\theta_{23}$ .
- Understanding at a fundamental level the mechanism giving rise to neutrino masses and mixing and to  $L_l$ -non-conservation. This includes understanding the origin of the patterns of  $\nu$ -mixing and  $\bar{\nu}$ -masses suggested by the data. Are the observed patterns of  $\nu$ -mixing and of  $\Delta m_{21,31}^2$  related to the existence of a new fundamental symmetry of particle interactions? Is there any relation between quark mixing and neutrino mixing? What is the physical origin of CP violation phases in the neutrino mixing matrix  $U$ ? Is there any relation (correlation) between the (values of) CP violation phases and mixing angles in  $U$ ? Progress in the theory of neutrino mixing might also lead to a better understanding of the mechanism of generation of baryon asymmetry of the Universe.

The high precision measurement of the value of  $\sin^2 2\theta_{13}$  from the Daya Bay experiment and the subsequent results on  $\theta_{13}$  obtained by the RENO, Double Chooz and T2K collaborations (see Section 14.12), have far reaching implications. The measured relatively large value of  $\theta_{13}$  opened up the possibilities, in particular,

- i) for searching for CP violation effects in neutrino oscillation experiments with high intensity accelerator neutrino beams, like T2K, NO $\nu$ A, etc.
- ii) for determining the sign of  $\Delta m_{32}^2$ , and thus the type of neutrino mass spectrum (“neutrino mass ordering”) in the long baseline neutrino oscillation experiments at accelerators (NO $\nu$ A, etc.), in the experiments studying the oscillations of atmospheric neutrinos (PINGU [82], ORCA [83,84], Hyper-Kamiokande [200], INO [85]), as well as in experiments with reactor antineutrinos [86–91].

There are also long term plans extending beyond 2025 for searches for CP violation and neutrino mass spectrum (ordering) determination in long baseline neutrino oscillation experiments with accelerator neutrino beams (see, *e.g.*, Refs. [93,94]). The successful realization of this research program would be a formidable task and would require many years of extraordinary experimental efforts aided by intensive theoretical investigations and remarkable investments.

## 15. Quark Model

Revised August 2017 by C. Amsler (Stefan Meyer Institute for Subatomic Physics, Vienna), T. DeGrand (University of Colorado, Boulder), and B. Krusche (University of Basel).

The quarks are strongly interacting spin-1/2 fermions, whose parity is positive by convention. The charges of the  $u$ ,  $c$ , and  $t$  quarks are  $+2/3$ , while those of the  $d$ ,  $s$ , and  $b$  are  $-1/3$ . Their anti-quarks have the opposite charges and parities. By convention, the  $s$  quark is said to have negative strangeness and the  $c$  quark positive charm. The two lightest quarks,  $u$  and  $d$ , obey to a high degree an SU(2) symmetry called isospin, with  $u$  having  $I_z = 1/2$  and  $d$  having  $I_z = -1/2$ . The other quarks can be assigned zero isospin.

Quarks have baryon number  $\mathcal{B} = 1/3$ , while anti-quarks have  $\mathcal{B} = -1/3$ . The mesons, which are pairs of quarks and anti-quarks, have  $\mathcal{B} = 0$  and can be characterized by their intrinsic spin  $s$ , orbital angular momentum  $\ell$ , and total spin  $J$ , lying between  $|\ell - s|$  and  $\ell + s$ . The charge conjugation, or  $C$ , of meson is  $(-1)^{\ell+s}$  while its parity is  $(-1)^{\ell+1}$ .  $G$ -parity combines the charge-conjugation and isospin symmetries:  $G = Ce^{-i\pi I_y}$ . Mesons made of a quark and its antiquark are  $G$ -parity eigenstates with  $G = (-1)^{I+\ell+s}$ .

The three lightest quarks,  $u$ ,  $d$ , and  $s$ , respect an approximate symmetry, flavor SU(3), with quarks belonging to the **3** representation and anti-quarks to the  **$\bar{3}$**  representation. The quark-anti-quark states made from  $u$ ,  $d$ , and  $s$  can be classified according to

$$\mathbf{3} \otimes \mathbf{\bar{3}} = \mathbf{8} \oplus \mathbf{1}. \quad (15.2)$$

A fourth quark such as charm  $c$  can be included by extending SU(3) to SU(4). However, SU(4) is badly broken owing to the much heavier  $c$  quark. Nevertheless, in an SU(4) classification, the sixteen mesons are grouped into a 15-plet and a singlet:

$$\mathbf{4} \otimes \mathbf{\bar{4}} = \mathbf{15} \oplus \mathbf{1}. \quad (15.3)$$

Baryons are made of three quarks (aside from a five-quark state recently observed at the LHC), allowing for more complex possibilities. The flavor SU(3) content of baryons made of  $u$ ,  $d$ , and  $s$  is governed by

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1}. \quad (15.23)$$

The intrinsic spin of the three quarks yields either  $s = 1/2$  or  $s = 3/2$ . The proton and neutron are members of an octet, while the spin-3/2  $\Delta^{++}$  is a member of a decuplet.

The strong interactions are described by the color SU(3) gauge theory, with each quark coming in three “colors.” The color triplets interact through a color octet of gluons, gauge vector bosons. These are responsible for the formation of the bound states, mesons and baryons.

## 21. Big-Bang Cosmology

Revised September 2017 by K.A. Olive (University of Minnesota) and J.A. Peacock (University of Edinburgh).

### 21.1.1. *The Robertson-Walker Universe :*

The observed homogeneity and isotropy enable us to write the most general expression for a space-time metric which has a (3D) maximally symmetric subspace of a 4D space-time, known as the Robertson-Walker metric:

$$ds^2 = dt^2 - R^2(t) \left[ \frac{dr^2}{1 - kr^2} + r^2(d\theta^2 + \sin^2 \theta d\phi^2) \right]. \quad (21.1)$$

Note that we adopt  $c = 1$  throughout. By rescaling the radial coordinate, we can choose the curvature constant  $k$  to take only the discrete values  $+1$ ,  $-1$ , or  $0$  corresponding to closed, open, or spatially flat geometries.

### 21.1.3. *The Friedmann equations of motion :*

The cosmological equations of motion are derived from Einstein's equations

$$\mathcal{R}_{\mu\nu} - \frac{1}{2}g_{\mu\nu}\mathcal{R} = 8\pi G_N T_{\mu\nu} + \Lambda g_{\mu\nu}. \quad (21.6)$$

It is common to assume that the matter content of the Universe is a perfect fluid, for which

$$T_{\mu\nu} = -pg_{\mu\nu} + (p + \rho)u_\mu u_\nu, \quad (21.7)$$

where  $g_{\mu\nu}$  is the space-time metric described by Eq. (21.1),  $p$  is the isotropic pressure,  $\rho$  is the energy density and  $u = (1, 0, 0, 0)$  is the velocity vector for the isotropic fluid in co-moving coordinates. With the perfect fluid source, Einstein's equations lead to the Friedmann equations

$$H^2 \equiv \left( \frac{\dot{R}}{R} \right)^2 = \frac{8\pi G_N \rho}{3} - \frac{k}{R^2} + \frac{\Lambda}{3}, \quad (21.8)$$

and

$$\frac{\ddot{R}}{R} = \frac{\Lambda}{3} - \frac{4\pi G_N}{3} (\rho + 3p), \quad (21.9)$$

where  $H(t)$  is the Hubble parameter and  $\Lambda$  is the cosmological constant. The first of these is sometimes called the Friedmann equation. Energy conservation via  $T_{;\mu}^{\mu\nu} = 0$ , leads to a third useful equation

$$\dot{\rho} = -3H(\rho + p). \quad (21.10)$$

Eq. (21.10) can also be simply derived as a consequence of the first law of thermodynamics.

### 21.1.5. *Standard Model solutions :*

Let us first assume a general equation of state parameter for a single component,  $w = p/\rho$  which is constant. In this case, Eq. (21.10) can be written as  $\dot{\rho} = -3(1+w)\rho\dot{R}/R$  and is easily integrated to yield

$$\rho \propto R^{-3(1+w)}. \quad (21.16)$$

Curvature domination occurs at rather late times (if a cosmological constant term does not dominate sooner). For  $w \neq -1$ ,

$$R(t) \propto t^{2/[3(1+w)]}. \quad (21.17)$$

**21.1.5.2. A Radiation-dominated Universe:**

In the early hot and dense Universe, it is appropriate to assume an equation of state corresponding to a gas of radiation (or relativistic particles) for which  $w = 1/3$ . In this case, Eq. (21.16) becomes  $\rho \propto R^{-4}$ . Similarly, one can substitute  $w = 1/3$  into Eq. (21.17) to obtain

$$R(t) \propto t^{1/2}; \quad H = 1/2t. \quad (21.18)$$

**21.1.5.3. A Matter-dominated Universe:**

Non-relativistic matter eventually dominates the energy density over radiation. A pressureless gas ( $w = 0$ ) leads to the expected dependence  $\rho \propto R^{-3}$ , and, if  $k = 0$ , we get

$$R(t) \propto t^{2/3}; \quad H = 2/3t. \quad (21.19)$$

**21.1.5.4. A Universe dominated by vacuum energy:**

If there is a dominant source of vacuum energy, acting as a cosmological constant with equation of state  $w = -1$ . This leads to an exponential expansion of the Universe:

$$R(t) \propto e^{\sqrt{\Lambda/3}t}. \quad (21.20)$$

**21.3. The Hot Thermal Universe****21.3.2. Radiation content of the Early Universe :**

At the very high temperatures associated with the early Universe, massive particles are pair produced, and are part of the thermal bath. If for a given particle species  $i$  we have  $T \gg m_i$ , then we can neglect the mass and the thermodynamic quantities are easily computed. In general, we can approximate the energy density (at high temperatures) by including only those particles with  $m_i \ll T$ . In this case, we have

$$\rho = \left( \sum_B g_B + \frac{7}{8} \sum_F g_F \right) \frac{\pi^2}{30} T^4 \equiv \frac{\pi^2}{30} N(T) T^4, \quad (21.42)$$

where  $g_{B(F)}$  is the number of degrees of freedom of each boson (fermion) and the sum runs over all boson and fermion states with  $m \ll T$ . Eq. (21.42) defines the effective number of degrees of freedom,  $N(T)$ , by taking into account new particle degrees of freedom as the temperature is raised.

The value of  $N(T)$  at any given temperature depends on the particle physics model. In the standard  $SU(3) \times SU(2) \times U(1)$  model, we can specify  $N(T)$  up to temperatures of  $O(100)$  GeV. The change in  $N$  (ignoring mass effects) can be seen in the table below. At higher temperatures,  $N(T)$  will be model-dependent.

In the radiation-dominated epoch, Eq. (21.10) can be integrated (neglecting the  $T$ -dependence of  $N$ ) giving us a relationship between the age of the Universe and its temperature

$$t = \left( \frac{90}{32\pi^3 G_N N(T)} \right)^{1/2} T^{-2}. \quad (21.43)$$

Put into a more convenient form

$$t T_{\text{MeV}}^2 = 2.4 [N(T)]^{-1/2}, \quad (21.44)$$

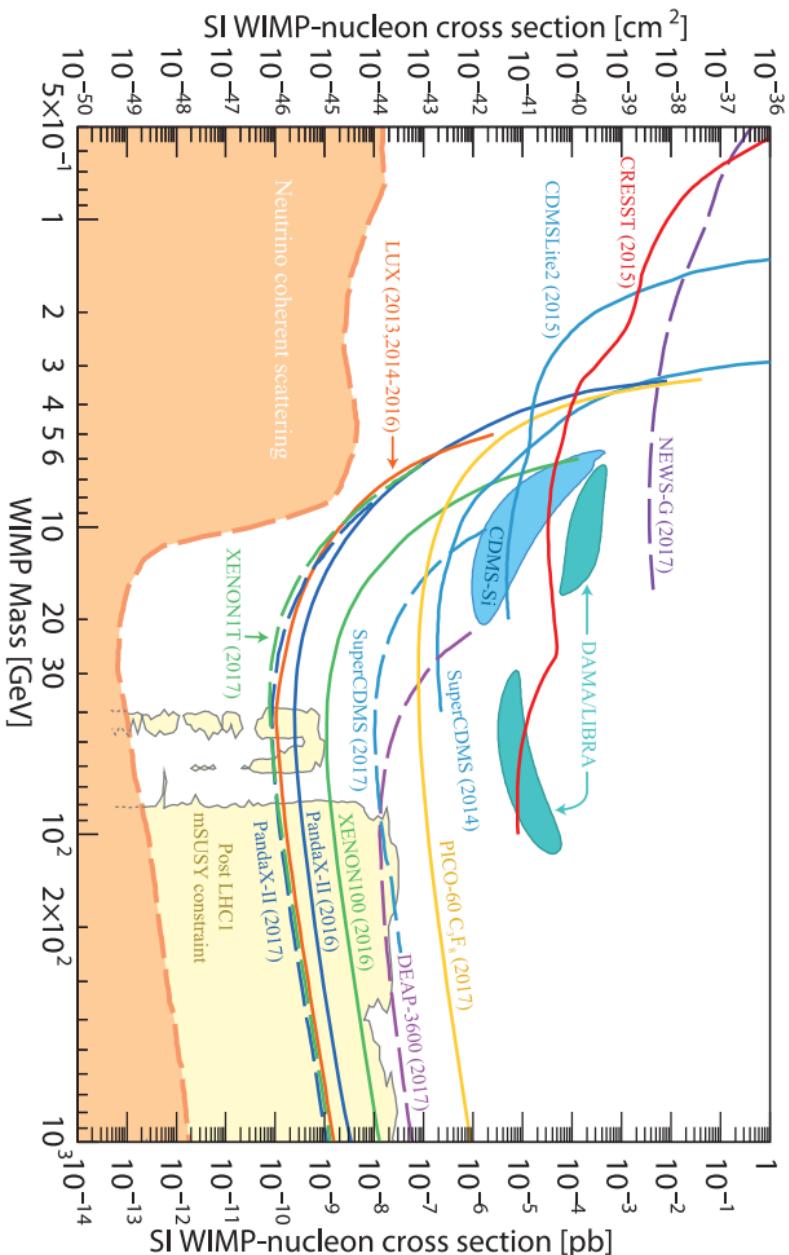

where  $t$  is measured in seconds and  $T_{\text{MeV}}$  in units of MeV.

## 26. Dark Matter

Revised Sept. 2017 by M. Drees (Bonn), G. Gerbier (Queen's, Canada).

Highlights from full review.

WIMPs should be gravitationally trapped inside galaxies and should have the adequate density profile to account for the observed rotational curves. These two constraints determine the main features of experimental detection of WIMPs. WIMPs interact with ordinary matter through elastic scattering on nuclei. With expected WIMP masses in the range 10 GeV to 10 TeV, typical nuclear recoil energies are of order of 1 to 100 keV.

**Figure 26.1:** WIMP cross sections for spin-independent coupling versus mass. The DAMA/LIBRA and CDMS-Si enclosed areas are regions of interest from possible signal events. The yellow area shows a scan of the parameter space of 4 typical SUSY models.

## 28. Cosmic Microwave Background

Revised August 2017 by D. Scott (University of British Columbia) and G.F. Smoot (UCB/LBNL).

### 28.2. CMB Spectrum

It is well known that the spectrum of the microwave background is very precisely that of blackbody radiation, whose temperature evolves with redshift as  $T(z) = T_0(1 + z)$  in an expanding universe.

### 28.3. Description of CMB Anisotropies

Observations show that the CMB contains temperature anisotropies at the  $10^{-5}$  level and polarization anisotropies at the  $10^{-6}$  (and lower) level, over a wide range of angular scales. These anisotropies are usually expressed by using a spherical harmonic expansion of the CMB sky:

$$T(\theta, \phi) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\theta, \phi)$$

(with the linear polarization pattern written in a similar way using the so-called spin-2 spherical harmonics). Increasing angular resolution requires that the expansion goes to higher and higher multipoles. Because there are only very weak phase correlations seen in the CMB sky and since we notice no preferred direction, the vast majority of the cosmological information is contained in the temperature 2-point function, *i.e.*, the variance as a function only of angular separation. Equivalently, the power per unit  $\ln \ell$  is  $\ell \sum_m |a_{\ell m}|^2 / 4\pi$ .

#### 28.3.1. The Monopole :

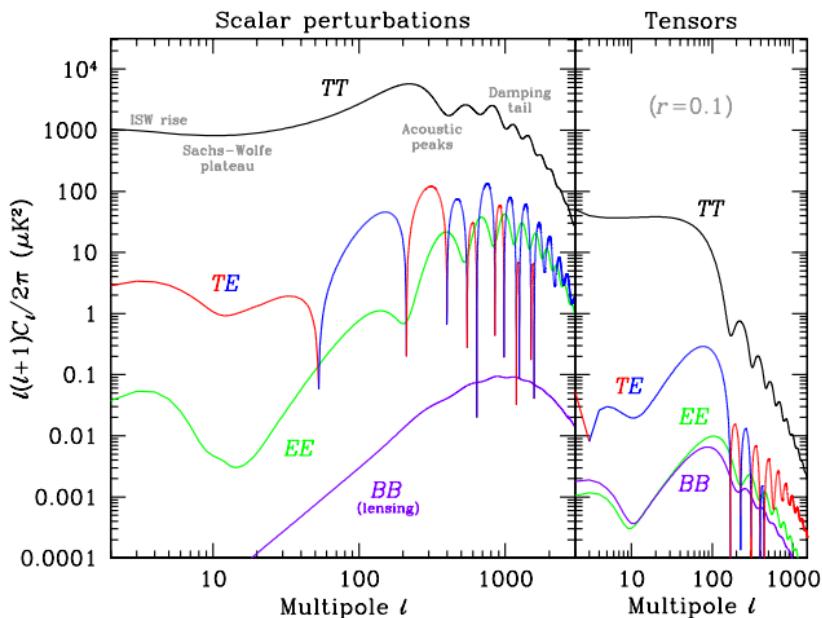

The CMB has a mean temperature of  $T_\gamma = 2.7255 \pm 0.0006$  K ( $1\sigma$ ) [21], which can be considered as the monopole component of CMB maps,  $a_{00}$ . Since all mapping experiments involve difference measurements, they are insensitive to this average level; monopole measurements can only be made with absolute temperature devices, such as the FIRAS instrument on the *COBE* satellite [22]. The measured  $kT_\gamma$  is equivalent to 0.234 meV or  $4.60 \times 10^{-10} m_e c^2$ . A blackbody of the measured temperature has a number density  $n_\gamma = (2\zeta(3)/\pi^2) T_\gamma^3 \simeq 411 \text{ cm}^{-3}$ , energy density  $\rho_\gamma = (\pi^2/15) T_\gamma^4 \simeq 4.64 \times 10^{-34} \text{ g cm}^{-3} \simeq 0.260 \text{ eV cm}^{-3}$ , and a fraction of the critical density  $\Omega_\gamma \simeq 5.38 \times 10^{-5}$ .

#### 28.3.2. The Dipole :

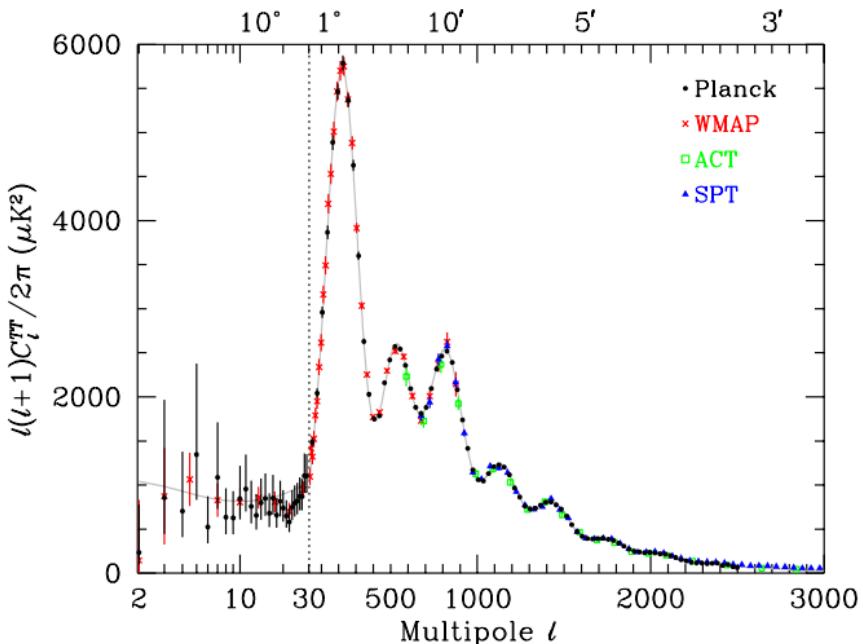

The largest anisotropy is in the  $\ell = 1$  (dipole) first spherical harmonic, with amplitude  $3.3645 \pm 0.0020$  mK [12]. The dipole is interpreted to be the result of the Doppler boosting of the monopole caused by the solar system motion relative to the nearly isotropic blackbody field, as broadly confirmed by measurements of the radial velocities of local galaxies (*e.g.*, Ref. [23]).

#### 28.3.3. Higher-Order Multipoles :

The variations in the CMB temperature maps at higher multipoles ( $\ell \geq 2$ ) are interpreted as being mostly the result of perturbations in the density of the early Universe, manifesting themselves at the epoch of the last scattering of the CMB photons.

**Figure 28.1:** Theoretical CMB anisotropy power spectra, using the best-fitting  $\Lambda\text{CDM}$  model from *Planck*, calculated using CAMB. The panel on the left shows the theoretical expectation for scalar perturbations, while the panel on the right is for tensor perturbations, with an amplitude set to  $r = 0.1$  for illustration.

**Figure 28.2:** CMB temperature anisotropy band-power estimates from the *Planck*, *WMAP*, *ACT*, and *SPT* experiments. The acoustic peaks and damping region are very clearly observed, with no need for a theoretical curve to guide the eye; however, the curve plotted is the best-fit *Planck*  $\Lambda\text{CDM}$  model.

## 29. Cosmic Rays

Revised October 2017 by J.J. Beatty (Ohio State Univ.), J. Matthews (Louisiana State Univ.), and S.P. Wakely (Univ. of Chicago).

Cosmic ray spectra are expressed in terms of differential intensity  $I$  with units [ $\text{m}^{-2}\text{s}^{-1}\text{sr}^{-1}\mathcal{E}^{-1}$ ], where the unit for  $\mathcal{E}$  is chosen from energy per nucleon, energy per nucleus, and magnetic rigidity depending on the application.

### *Primary Cosmic Rays*

The intensity of primary nucleons in the energy range from several GeV to somewhat beyond 100 TeV is given approximately by

$$I_N(E) \approx 1.8 \times 10^4 (E/1 \text{ GeV})^{-\alpha} \frac{\text{nucleons}}{\text{m}^2 \text{ s sr GeV}} \quad (29.2)$$

where  $E$  is the energy-per-nucleon (including rest mass energy) and  $\alpha = 2.7$  is the differential spectral index. About 74% of the primary nucleons are free protons and about 70% of the rest are bound in helium nuclei. At higher energies, the all-particle spectrum in terms of energy per *nucleus* is used. Above a few times  $10^{15}$  eV the spectrum steepens at the ‘knee’, again steepens at a ‘second knee’ near  $10^{17}$  eV, and flattens at the ‘ankle’ near  $10^{18.5}$  eV. Above  $5 \times 10^{19}$  eV the spectrum steepens rapidly due to the onset of inelastic interactions with the cosmic microwave background.

### *Secondary Cosmic Rays at Sea Level*

Cosmic rays at sea level are mostly muons from air showers induced by primary cosmic rays. The integral intensity of vertical muons above 1 GeV/c at sea level is  $\approx 70 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The overall angular distribution of muons at the ground as a function of zenith angle  $\theta$  is  $\propto \cos^2 \theta$ . This results in a muon rate of about  $1 \text{ cm}^{-2} \text{ min}^{-1}$  for a thin horizontal detector. In addition to muons, there is a significant component of electrons and positrons with an integral vertical intensity very approximately 30, 6, and  $0.2 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$  above 10, 100, and 1000 MeV respectively, with a complicated angular dependence. The integral intensity of vertical protons above 1 GeV/c at sea level is  $\approx 0.9 \text{ m}^{-2}\text{sr}^{-1}$ , accompanied by neutrons at about 1/3 of the proton flux.

### *Particles in the Atmosphere and Underground*

At altitudes  $h$  between 1 and 6 km above sea level the vertical flux of particles with  $E > 1$  GeV is dominated by muons with a flux of  $\approx 100 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1} \times (h/\text{km})^{0.42}$ .

The underground charged particle flux is predominantly muons. For ice or water at depth  $d > 1$  km the vertical flux is  $\approx 2.2 \times 10^{-2} \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1} \times (d/\text{km})^{-4.5}$ . Below depths of  $\approx 20$  km w.e., most remaining muons are produced by neutrino interactions. The upward-going vertical intensity of muons above 2 GeV is  $\approx 2 \times 10^{-9} \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The horizontal intensity below 20 km w.e. is about twice the upward-going vertical intensity.

## 30. Accelerator Physics of Colliders

Revised March 2018 by M.J. Syphers (NIU/FNAL) and F. Zimmermann (CERN).

The number of events,  $N_{exp}$ , is the product of the cross section of interest,  $\sigma_{exp}$ , and the time integral over the instantaneous *luminosity*,  $\mathcal{L}$ :

$$N_{exp} = \sigma_{exp} \times \int \mathcal{L}(t) dt. \quad (30.1)$$

Today's colliders all employ bunched beams. If two bunches containing  $n_1$  and  $n_2$  particles collide head-on with frequency  $f_{coll}$ , a basic expression for the geometric luminosity is

$$\mathcal{L} = f_{coll} \frac{n_1 n_2}{4\pi \sigma_x \sigma_y} \quad (30.2)$$

where  $\sigma_x$  and  $\sigma_y$  characterize the rms transverse beam sizes in the horizontal (bending) and vertical directions.

For a beam with a Gaussian distribution in  $x, x'$ , the area containing one standard deviation  $\sigma_x$ , divided by  $\pi$ , is used as the definition of emittances:

$$\varepsilon_x \equiv \frac{\sigma_x^2}{\beta_x}, \quad (30.9)$$

with a corresponding expression in the other transverse direction,  $y$ .

Eq. (30.2) can be recast in terms of emittances and amplitude functions as

$$\mathcal{L} = f \frac{n_1 n_2}{4\pi \sqrt{\epsilon_x \beta_x^* \epsilon_y \beta_y^*}} \mathcal{F}. \quad (30.10)$$

Here,  $\mathcal{F} \leq 1$  is a factor that takes into account effects such as crossing angles, hour glass factors, pinch effects, and so on.  $\beta^*$  is the value of the amplitude function at the interaction point.

A bunch in beam 1 presents a (nonlinear) lens to a particle in beam 2 resulting in changes to the particle's transverse tune with a range characterized by the beam-beam parameter

$$\xi_{y,2} = \left( \frac{\mu_0}{8\pi^2} \right) \frac{q_1 q_2 n_1 \beta_{y,2}^*}{m_{A,2} \gamma_2 \sigma_{y,1}^* (\sigma_{x,1}^* + \sigma_{y,1}^*)} \quad (30.11)$$

where  $q_1$  ( $q_2$ ) denotes the particle charge of beam 1 (2) in units of the elementary charge,  $m_{A,2}$  the mass of beam-2 particles, and  $\mu_0$  the vacuum permeability.

Eq. (30.2) for linear colliders can be written as:

$$\mathcal{L} \approx \frac{137}{8\pi r_e} \frac{P_{\text{wall}}}{E_{cm}} \frac{\eta}{\sigma_y^*} N_\gamma H_D. \quad (30.12)$$

Here,  $P_{\text{wall}}$  is the total wall-plug power of the collider,  $\eta \equiv P_b/P_{\text{wall}}$  the efficiency of converting wall-plug power into beam power  $P_b = f_{coll} n E_{cm}$ ,  $E_{cm}$  the cms energy,  $n$  ( $= n_1 = n_2$ ) the bunch population, and  $\sigma_y^*$  the vertical rms beam size at the collision point. In formulating Eq. (30.12) the number of beamstrahlung photons emitted per  $e^\pm$ , was approximated as  $N_\gamma \approx 2\alpha r_e n / \sigma_x^*$ , where  $\alpha \approx 1/137$  denotes the fine-structure constant.

Tentative parameters of selected future high-energy colliders. Parameters associated with different beam energy scenarios are command-separated. Quantities are, where appropriate, r.m.s.;  $H$  and  $V$  indicate horizontal and vertical directions. See full *Review* for complete tables. Parameters for other proposed high-energy colliders, including a muon collider, can be found in the full *Review*.

### 31. High-Energy Collider Parameters

Updated in March 2018 with numbers received from representatives of the colliders (contact E. Pianori, LBNL). Except for SuperKEKB, where design values are quoted, the table shows parameter values as achieved by March 1, 2018. Quantities are, where appropriate, r.m.s.; energies refer to beam energy;  $H$  and  $V$  indicate horizontal and vertical directions. Only selected colliders operating in 2016 and 2017 are included. See full *Review* for complete tables.

### 33. Passage of Particles Through Matter

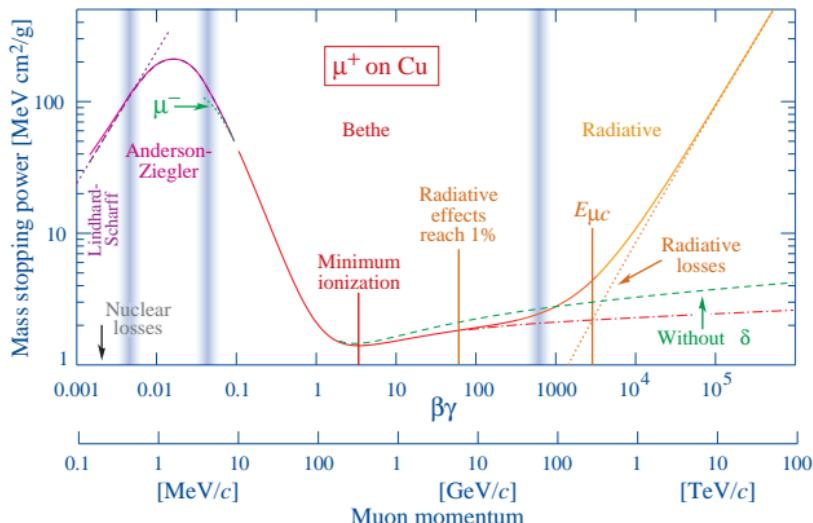

Revised August 2015 by H. Bichsel (University of Washington), D.E. Groom (LBNL), and S.R. Klein (LBNL).

This review covers the interactions of photons and electrically charged particles in matter, concentrating on energies of interest for high-energy physics and astrophysics and processes of interest for particle detectors.

**Table 33.1:** Summary of variables used in this section. The kinematic variables  $\beta$  and  $\gamma$  have their usual relativistic meanings.

Symbol	Definition	Value or (usual) units
$m_e c^2$	electron mass $\times c^2$	0.510 998 9461(31) MeV
$r_e$	classical electron radius $e^2/4\pi\epsilon_0 m_e c^2$	2.817 940 3227(19) fm
$\alpha$	fine structure constant $e^2/4\pi\epsilon_0 \hbar c$	1/137.035 999 139(31)
$N_A$	Avogadro's number	$6.022\ 140\ 857(74) \times 10^{23}$ mol $^{-1}$
$\rho$	density	g cm $^{-3}$
$x$	mass per unit area	g cm $^{-2}$
$M$	incident particle mass	MeV/ $c^2$
$E$	incident part. energy $\gamma M c^2$	MeV
$T$	kinetic energy, $(\gamma - 1) M c^2$	MeV
$W$	energy transfer to an electron in a single collision	MeV
$k$	bremsstrahlung photon energy	MeV
$z$	charge number of incident particle	
$Z$	atomic number of absorber	
$A$	atomic mass of absorber	g mol $^{-1}$
$K$	$4\pi N_A r_e^2 m_e c^2$ (Coefficient for $dE/dx$ )	0.307 075 MeV mol $^{-1}$ cm $^2$
$I$	mean excitation energy	eV ( <i>Nota bene!</i> )
$\delta(\beta\gamma)$	density effect correction to ionization energy loss	
$\hbar\omega_p$	plasma energy $\sqrt{4\pi N_e r_e^3} m_e c^2/\alpha$	$\sqrt{\rho \langle Z/A \rangle} \times 28.816$ eV └── $\rho$ in g cm $^{-3}$
$N_e$	electron density	(units of $r_e$ ) $^{-3}$
$w_j$	weight fraction of the $j$ th element in a compound or mixture	
$n_j$	$\propto$ number of $j$ th kind of atoms in a compound or mixture	
$X_0$	radiation length	g cm $^{-2}$
$E_c$	critical energy for electrons	MeV
$E_{\mu c}$	critical energy for muons	GeV
$E_s$	scale energy $\sqrt{4\pi/\alpha} m_e c^2$	21.2052 MeV
$R_M$	Molière radius	g cm $^{-2}$

### 33.2. Electronic energy loss by heavy particles [1–33]

**Figure 33.1:** Mass stopping power ( $= \langle -dE/dx \rangle$ ) for positive muons in copper as a function of  $\beta\gamma = p/Mc$  over nine orders of magnitude in momentum (12 orders of magnitude in kinetic energy). Vertical bands indicate boundaries between different approximations discussed in the text.

#### 33.2.2. Maximum energy transfer in a single collision :

For a particle with mass  $M$ ,

$$W_{\max} = \frac{2m_e c^2 \beta^2 \gamma^2}{1 + 2\gamma m_e/M + (m_e/M)^2}. \quad (33.4)$$

#### 33.2.3. Stopping power at intermediate energies :

The mean rate of energy loss by moderately relativistic charged heavy particles is well-described by the “Bethe equation,”

$$\left\langle -\frac{dE}{dx} \right\rangle = K z^2 \frac{Z}{A} \frac{1}{\beta^2} \left[ \frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 W_{\max}}{I^2} - \beta^2 - \frac{\delta(\beta\gamma)}{2} \right]. \quad (33.5)$$

This is the *mass stopping power*; with the symbol definitions and values given in Table 33.1, the units are  $\text{MeV g}^{-1}\text{cm}^2$ .  $\langle -dE/dx \rangle$  defined in this way is about the same for most materials, decreasing slowly with  $Z$ . The *linear stopping power*, in  $\text{MeV/cm}$ , is  $\langle -dE/dx \rangle \rho$ , where  $\rho$  is the density in  $\text{g/cm}^3$ .

As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (33.5) increases as  $\ln \beta\gamma$ . However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic rise. Parameterization of the density effect term  $\delta(\beta\gamma)$  in Eq. (33.5) is discussed in the full *Review*.

Few concepts in high-energy physics are as misused as  $\langle dE/dx \rangle$ . The mean is weighted by very rare events with large single-collision energy deposits. Even with samples of hundreds of events a dependable value for the mean energy loss cannot be obtained. Far better and more easily measured is the most probable energy loss, discussed below.

Although it must be used with cautions and caveats,  $\langle dE/dx \rangle$  as described in Eq. (33.5) still forms the basis of much of our understanding

of energy loss by charged particles. Extensive tables are available [[pdg.lbl.gov/AtomicNuclearProperties/](http://pdg.lbl.gov/AtomicNuclearProperties/)].

Eq. (33.5) may be integrated to find the total (or partial) “continuous slowing-down approximation” (CSDA) range  $R$ . Since  $dE/dx$  depends (nearly) only on  $\beta$ ,  $R/M$  is a function of  $E/M$  or  $pc/M$ .

### 33.2.9. Fluctuations in energy loss :

For detectors of moderate thickness  $x$  (*e.g.* scintillators or LAr cells), the energy loss probability distribution  $f(\Delta; \beta\gamma, x)$  is adequately described by the highly-skewed Landau (or Landau-Vavilov) distribution [24,25]. The most probable energy loss

$$\Delta_p = \xi \left[ \ln \frac{2mc^2\beta^2\gamma^2}{I} + \ln \frac{\xi}{I} + j - \beta^2 - \delta(\beta\gamma) \right], \quad (33.11)$$

where  $\xi = (K/2) \langle Z/A \rangle z^2(x/\beta^2)$  MeV for a detector with a thickness  $x$  in g cm<sup>-2</sup>, and  $j = 0.200$  [26]. While  $dE/dx$  is independent of thickness,  $\Delta_p/x$  scales as  $a \ln x + b$ . This most probable energy loss reaches a (Fermi) plateau rather than continuing  $\langle dE/dx \rangle$ ’s logarithmic rise with increasing energy.

## 33.4. Photon and electron interactions in matter

At low energies electrons and positrons primarily lose energy by ionization, although other processes (Møller scattering, Bhabha scattering,  $e^+$  annihilation) contribute. While ionization loss rates rise logarithmically with energy, bremsstrahlung losses rise nearly linearly (fractional loss is nearly independent of energy), and dominates above the critical energy (Sec. 33.4.4 below), a few tens of MeV in most materials

### 33.4.1. Collision energy losses by $e^\pm$ :

Stopping power differs somewhat for electrons and positrons, and both differ from stopping power for heavy particles because of the kinematics, spin, charge, and the identity of the incident electron with the electrons that it ionizes. Complete discussions and tables can be found in Refs. 10, 11, and 29 in the full *Review*.

### 33.4.2. Radiation length :

High-energy electrons predominantly lose energy in matter by bremsstrahlung, and high-energy photons by  $e^+e^-$  pair production. The characteristic amount of matter traversed for these related interactions is called the radiation length  $X_0$ , usually measured in g cm<sup>-2</sup>.  $X_0$  has been calculated and tabulated by Y.S. Tsai [42]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A} \left\{ Z^2 [L_{\text{rad}} - f(Z)] + Z L'_{\text{rad}} \right\}. \quad (33.26)$$

For  $A = 1$  g mol<sup>-1</sup>,  $4\alpha r_e^2 N_A / A = (716.408 \text{ g cm}^{-2})^{-1}$ .  $L_{\text{rad}}$  and  $L'_{\text{rad}}$  are tabulated in the full *Review*, where a 4-place approximation for  $f(z)$  is also given.

### 33.4.3. Bremsstrahlung energy loss by $e^\pm$ :

At very high energies and except at the high-energy tip of the bremsstrahlung spectrum, the cross section can be approximated in the “complete screening case” as [42]

$$d\sigma/dk = (1/k) 4\alpha r_e^2 \left\{ \left( \frac{4}{3} - \frac{4}{3}y + y^2 \right) [Z^2(L_{\text{rad}} - f(Z)) + Z L'_{\text{rad}}] + \frac{1}{9}(1-y)(Z^2 + Z) \right\}, \quad (33.29)$$

where  $y = k/E$  is the fraction of the electron’s energy transferred to the radiated photon. At small  $y$  (the “infrared limit”) the term on the second

line ranges from 1.7% (low  $Z$ ) to 2.5% (high  $Z$ ) of the total. If it is ignored and the first line simplified with the definition of  $X_0$  given in Eq. (33.26), we have

$$\frac{d\sigma}{dk} = \frac{A}{X_0 N_A k} \left( \frac{4}{3} - \frac{4}{3}y + y^2 \right) . \quad (33.30)$$

### 33.4.4. Critical energy :

An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The *critical energy*  $E_c$  is sometimes defined as the energy at which the two loss rates are equal [49]. Among alternate definitions is that of Rossi [2], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation  $|dE/dx|_{\text{brems}} \approx E/X_0$ . This form has been found to describe transverse electromagnetic shower development more accurately.

Values of  $E_c$  for electrons can be reasonably well described by  $(610 \text{ MeV})/(Z + 1.24)$  for solids and  $(710 \text{ MeV})/(Z + 0.92)$  for gases.  $E_c$  for both electrons and positrons in more than 350 materials can be found at [pdg.lbl.gov/AtomicNuclearProperties](http://pdg.lbl.gov/AtomicNuclearProperties).

### 33.4.5. Energy loss by photons :

At low energies the photoelectric effect dominates, although Compton scattering, Rayleigh scattering, and photonuclear absorption also contribute. The photoelectric cross section is characterized by discontinuities (absorption edges) as thresholds for photoionization of various atomic levels are reached. Pair production dominates at high energies, but is suppressed at ultrahigh energies because of quantum mechanical interference between amplitudes from different scattering centers (LPM effect).

At still higher photon and electron energies, where the bremsstrahlung and pair production cross-sections are heavily suppressed by the LPM effect, photonuclear and electronuclear interactions predominate over electromagnetic interactions. At photon energies above about  $10^{20} \text{ eV}$ , for example, photons usually interact hadronically.

## 33.5. Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energies.

The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is convenient to introduce the scale variables

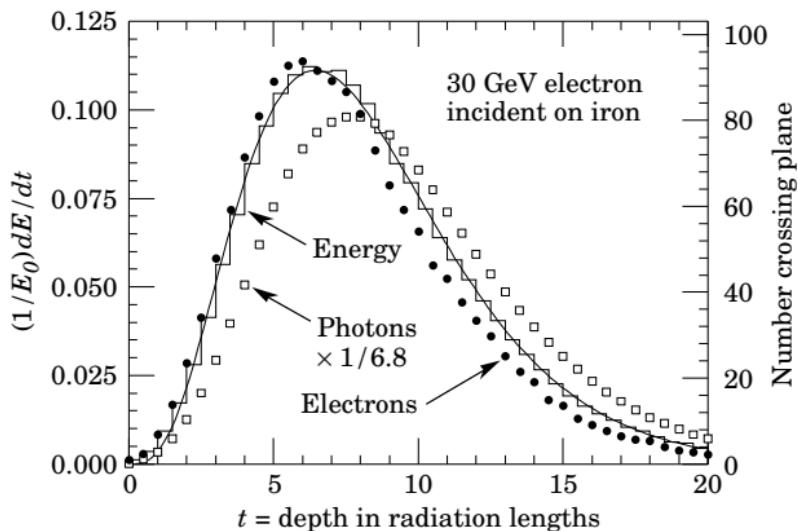

$$t = x/X_0 , \quad y = E/E_c , \quad (33.35)$$

so that distance is measured in units of radiation length and energy in units of critical energy.

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [59],

$$\frac{dE}{dt} = E_0 b \frac{(bt)^{a-1} e^{-bt}}{\Gamma(a)} , \quad (33.36)$$

at energies from 1 GeV to 100 GeV.

**Figure 33.20:** An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution.

### 33.6. Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. These contributions increase almost linearly with energy. It is convenient to write the average rate of muon energy loss as [72]

$$-dE/dx = a(E) + b(E) E . \quad (33.41)$$

Here  $a(E)$  is the ionization energy loss given by Eq. (33.5), and  $b(E) E$  is the sum of  $e^+e^-$  pair production, bremsstrahlung, and photonuclear contributions. These are subject large fluctuations, particularly at higher energies.

To the approximation that the slowly-varying functions  $a(E)$  and  $b(E)$  are constant, the mean range  $x_0$  of a muon with initial energy  $E_0$  is given by

$$x_0 \approx (1/b) \ln(1 + E_0/E_{\mu c}) , \quad (33.42)$$

where  $E_{\mu c} = a/b$ .

The “muon critical energy”  $E_{\mu c}$  can be defined as the energy at which radiative and ionization losses are equal, and can be found by solving  $E_{\mu c} = a(E_{\mu c})/b(E_{\mu c})$ . This definition is different from the Rossi definition we used for electrons. It decreases with  $Z$ , and is several hundred GeV for iron. It is given for the elements and many other materials in [pdg.lbl.gov/AtomicNuclearProperties](http://pdg.lbl.gov/AtomicNuclearProperties).

### 33.7. Cherenkov and transition radiation

A charged particle radiates if its velocity is greater than the local phase velocity of light (Cherenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy and cosmic-ray physics detectors.

### 33.7.1. Optical Cherenkov radiation :

The angle  $\theta_c$  of Cherenkov radiation, relative to the particle's direction, for a particle with velocity  $\beta c$  in a medium with index of refraction  $n$  is

$$\cos \theta_c = (1/n\beta)$$

or  $\tan \theta_c = \sqrt{\beta^2 n^2 - 1}$

$$\approx \sqrt{2(1 - 1/n\beta)} \quad \text{for small } \theta_c, \text{ e.g. in gases.} \quad (33.43)$$

The threshold velocity  $\beta_t$  is  $1/n$ . Values of  $n - 1$  for various commonly used gases are given as a function of pressure and wavelength in Ref. 78. Data for other commonly used materials are given in Ref. 79.

The number of photons produced per unit path length of a particle with charge  $ze$  and per unit energy interval of the photons is

$$\frac{d^2N}{dEdx} = \frac{\alpha z^2}{\hbar c} \sin^2 \theta_c = \frac{\alpha^2 z^2}{r_e m_e c^2} \left(1 - \frac{1}{\beta^2 n^2(E)}\right)$$

$$\approx 370 \sin^2 \theta_c(E) \text{ eV}^{-1} \text{cm}^{-1} \quad (z = 1), \quad (33.45)$$

or, equivalently,

$$\frac{d^2N}{dx d\lambda} = \frac{2\pi\alpha z^2}{\lambda^2} \left(1 - \frac{1}{\beta^2 n^2(\lambda)}\right). \quad (33.46)$$

### 33.7.2. Coherent radio Cherenkov radiation :

Coherent Cherenkov radiation is produced by many charged particles with a non-zero net charge moving through matter on an approximately common “wavefront”—for example, the electrons and positrons in a high-energy electromagnetic cascade. Near the end of a shower, when typical particle energies are below  $E_c$  (but still relativistic), a charge imbalance develops. Photons can Compton-scatter atomic electrons, and positrons can annihilate with atomic electrons to contribute even more photons which can in turn Compton scatter. These processes result in a roughly 20% excess of electrons over positrons in a shower. The net negative charge leads to coherent radio Cherenkov emission. The phenomenon is called the Askaryan effect [84]. The signals can be visible above backgrounds for shower energies as low as  $10^{17}$  eV; see Sec. 35.3.3 for more details.

### 33.7.3. Transition radiation :

The energy radiated when a particle with charge  $ze$  crosses the boundary between vacuum and a medium with plasma frequency  $\omega_p$  is

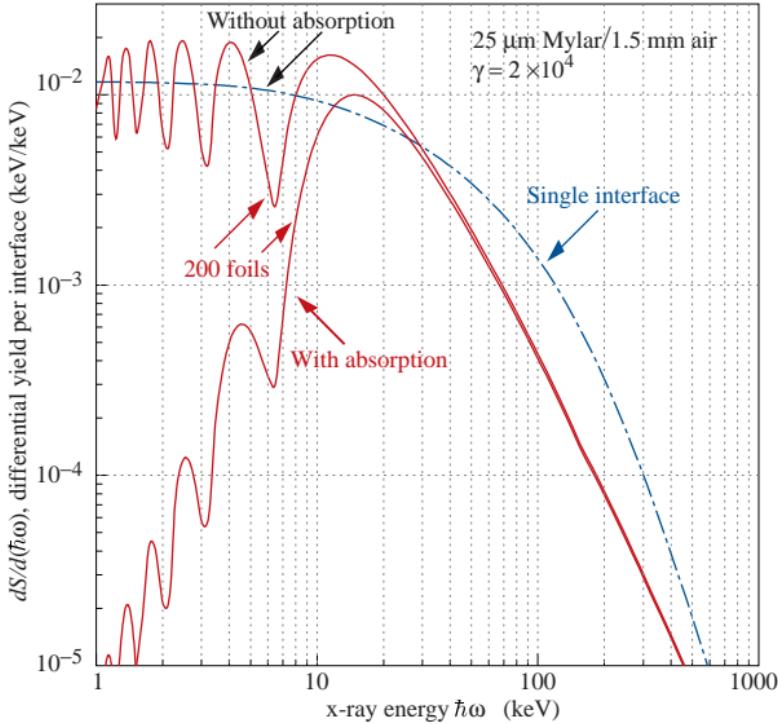

$$I = \alpha z^2 \gamma \hbar \omega_p / 3. \quad (33.47)$$

The plasma energy  $\hbar \omega_p$  is defined in Table 33.1.

For styrene and similar materials,  $\hbar \omega_p \approx 20$  eV; for air it is 0.7 eV. The number spectrum  $dN_\gamma/d(\hbar\omega)$  diverges logarithmically at low energies and decreases rapidly for  $\hbar\omega/\gamma\hbar\omega_p > 1$ . Inevitable absorption in a practical detector removes the divergence. About half the energy is emitted in the range  $0.1 \leq \hbar\omega/\gamma\hbar\omega_p \leq 1$ . The  $\gamma$  dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a particle with  $\gamma = 10^3$ , the radiated photons are in the soft x-ray range 2 to 40 keV.

The number of photons with energy  $\hbar\omega > \hbar\omega_0$  is given by the answer to problem 13.15 in Ref. 33,

$$N_\gamma(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi} \left[ \left( \ln \frac{\gamma \hbar \omega_p}{\hbar \omega_0} - 1 \right)^2 + \frac{\pi^2}{12} \right], \quad (33.49)$$

**Figure 33.27:** X-ray photon energy spectra for a radiator consisting of 200  $25\text{ }\mu\text{m}$  thick foils of Mylar with 1.5 mm spacing in air (solid lines) and for a single surface (dashed line).

within corrections of order  $(\hbar\omega_0/\gamma\hbar\omega_p)^2$ . The number of photons above a fixed energy  $\hbar\omega_0 \ll \gamma\hbar\omega_p$  thus grows as  $(\ln \gamma)^2$ , but the number above a fixed fraction of  $\gamma\hbar\omega_p$  (as in the example above) is constant. For example, for  $\hbar\omega > \gamma\hbar\omega_p/10$ ,  $N_\gamma = 2.519 \alpha z^2/\pi = 0.0059 \times z^2$ .

The particle stays “in phase” with the x ray over a distance called the formation length,  $d(\omega) = (2c/\omega)(1/\gamma^2 + \theta^2 + \omega_p^2/\omega^2)^{-1}$ . Most of the radiation is produced in this distance. Here  $\theta$  is the x-ray emission angle, characteristically  $1/\gamma$ . For  $\theta = 1/\gamma$  the formation length has a maximum at  $d(\gamma\omega_p/\sqrt{2}) = \gamma c/\sqrt{2} \omega_p$ . In practical situations it is tens of  $\mu\text{m}$ .

Since the useful x-ray yield from a single interface is low, in practical detectors it is enhanced by using a stack of  $N$  foil radiators—foils  $L$  thick, where  $L$  is typically several formation lengths—separated by gas-filled gaps. The amplitudes at successive interfaces interfere to cause oscillations about the single-interface spectrum. At increasing frequencies above the position of the last interference maximum ( $L/d(\omega) = \pi/2$ ), the formation zones, which have opposite phase, overlap more and more and the spectrum saturates,  $dI/d\omega$  approaching zero as  $L/d(\omega) \rightarrow 0$ . This is illustrated in Fig. 33.27 for a realistic detector configuration.

Although one might expect the intensity of coherent radiation from the stack of foils to be proportional to  $N^2$ , the angular dependence of the formation length conspires to make the intensity  $\propto N$ .

## 34. Particle Detectors at Accelerators

### 34.1. Introduction

This review summarizes the detector technologies employed at accelerator particle physics experiments. Several of these detectors are also used in a non-accelerator context and examples of such applications will be provided. The detector techniques which are specific to non-accelerator particle physics experiments are the subject of Chap. 35. More detailed discussions of detectors and their underlying physics can be found in books by Ferbel [1], Kleinknecht [2], Knoll [3], Green [4], Leroy & Ranchoita [5], and Grupen [6].

In Table 34.1 are given typical resolutions and deadtimes of common charged particle detectors. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. The spatial resolution refers to the intrinsic detector resolution, i.e. without multiple scattering. We note that analog detector readout can provide better spatial resolution than digital readout by measuring the deposited charge in neighboring channels. Quoted ranges attempt to be representative of both possibilities. The time resolution is defined by how accurately the time at which a particle crossed the detector can be determined. The deadtime is the minimum separation in time between two resolved hits on the same channel. Typical performance of calorimetry and particle identification are provided in the relevant sections below.

**Table 34.1:** Typical resolutions and deadtimes of common charged particle detectors. Revised November 2011.

Detector Type	Intrinsic Spatial Resolution (rms)	Time Resolution	Dead Time
Resistive plate chamber	$\lesssim 10 \text{ mm}$	1 ns (50 ps <sup>a</sup> )	—
Streamer chamber	$300 \mu\text{m}^b$	$2 \mu\text{s}$	100 ms
Liquid argon drift [7]	$\sim 175\text{--}450 \mu\text{m}$	$\sim 200 \text{ ns}$	$\sim 2 \mu\text{s}$
Scintillation tracker	$\sim 100 \mu\text{m}$	$100 \text{ ps}/n^c$	10 ns
Bubble chamber	$10\text{--}150 \mu\text{m}$	1 ms	50 ms <sup>d</sup>
Proportional chamber	$50\text{--}100 \mu\text{m}^e$	2 ns	20-200 ns
Drift chamber	$50\text{--}100 \mu\text{m}$	$2 \text{ ns}^f$	20-100 ns
Micro-pattern gas detectors	$30\text{--}40 \mu\text{m}$	$< 10 \text{ ns}$	10-100 ns
Silicon strip	pitch/(3 to 7) <sup>g</sup>	few ns <sup>h</sup>	$\lesssim 50 \text{ ns}^h$
Silicon pixel	$\lesssim 10 \mu\text{m}$	few ns <sup>h</sup>	$\lesssim 50 \text{ ns}^h$
Emulsion	1 $\mu\text{m}$	—	—

<sup>a</sup> For multiple-gap RPCs.

<sup>b</sup>  $300 \mu\text{m}$  is for 1 mm pitch (wirespacing/ $\sqrt{12}$ ).

<sup>c</sup>  $n =$  index of refraction.

<sup>d</sup> Multiple pulsing time.

<sup>e</sup> Delay line cathode readout can give  $\pm 150 \mu\text{m}$  parallel to anode wire.

<sup>f</sup> For two chambers.

<sup>g</sup> The highest resolution (“7”) is obtained for small-pitch detectors ( $\lesssim 25 \mu\text{m}$ ) with pulse-height-weighted center finding.

<sup>h</sup> Limited by the readout electronics [8].

## 36. Radioactivity and Radiation Protection

Revised October 2017 by S. Roesler and M. Silari (CERN).

### 36.1. Definitions

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

- **Activity** (unit: Becquerel):

$$1 \text{ Bq} = 1 \text{ disintegration per second} (= 27 \text{ pCi}).$$

- **Absorbed dose** (unit: gray): The absorbed dose is the energy imparted by ionizing radiation in a volume element of a specified material divided by the mass of this volume element.

$$1 \text{ Gy} = 1 \text{ J/kg} (= 10^4 \text{ erg/g} = 100 \text{ rad})$$

$$= 6.24 \times 10^{12} \text{ MeV/kg deposited energy.}$$

- **Kerma** (unit: gray): Kerma is the sum of the initial kinetic energies of all charged particles liberated by indirectly ionizing particles in a volume element of the specified material divided by the mass of this volume element.

- **Exposure** (unit: C/kg of air [= 3880 Roentgen<sup>†</sup>]): The exposure is a measure of photon fluence at a certain point in space integrated over time, in terms of ion charge of either sign produced by secondary electrons in a small volume of air about the point. Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving (so-called charged particle equilibrium).

**Table 36.1:** Radiation weighting factors,  $w_R$ .

Radiation type	$w_R$
Photons	1
Electrons and muons	1
Neutrons, $E_n < 1 \text{ MeV}$	$2.5 + 18.2 \times \exp[-(\ln E_n)^2/6]$
$1 \text{ MeV} \leq E_n \leq 50 \text{ MeV}$	$5.0 + 17.0 \times \exp[-(\ln(2E_n))^2/6]$
$E_n > 50 \text{ MeV}$	$2.5 + 3.25 \times \exp[-(\ln(0.04E_n))^2/6]$
Protons and charged pions	2
Alpha particles, fission fragments, heavy ions	20

- **Equivalent dose** (unit: Sievert [= 100 rem (roentgen equivalent in man)]): The equivalent dose  $H_T$  in an organ or tissue  $T$  is equal to the sum of the absorbed doses  $D_{T,R}$  in the organ or tissue caused by different radiation types  $R$  weighted with so-called radiation weighting factors  $w_R$ :

$$H_T = \sum_R w_R \times D_{T,R}. \quad (36.1)$$

---

<sup>†</sup> This unit is somewhat historical, but appears on some measuring instruments. One R is the amount of radiation required to liberate positive and negative charges of one electrostatic unit of charge in 1 cm<sup>3</sup> of air at standard temperature and pressure (STP)

It expresses long-term risks (primarily cancer and leukemia) from low-level chronic exposure. The values for  $w_R$  recommended recently by ICRP [2] are given in Table 36.1.

- **Effective dose** (unit: Sievert): The sum of the equivalent doses, weighted by the tissue weighting factors  $w_T$  ( $\sum_T w_T = 1$ ) of several organs and tissues  $T$  of the body that are considered to be most sensitive [2], is called “effective dose”  $E$ :

$$E = \sum_T w_T \times H_T . \quad (36.2)$$

### 36.2. Radiation levels [4]

- **Natural annual background**, all sources: Most world areas, whole-body equivalent dose rate  $\approx (1.0\text{--}13)$  mSv (0.1–1.3 rem). Can range up to 50 mSv (5 rem) in certain areas. U.S. average  $\approx 3.6$  mSv, including  $\approx 2$  mSv ( $\approx 200$  mrem) from inhaled natural radioactivity, mostly radon and radon daughters. (Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines. 0.1–0.2 mSv in open areas.)

- **Cosmic ray background** (sea level, mostly muons):  $\sim 1 \text{ min}^{-1} \text{ cm}^{-2} \text{ sr}^{-1}$ . For more accurate estimates and details, see the Cosmic Rays section (Sec. 29 of this *Review*).

- **Fluence** (per  $\text{cm}^2$ ) to deposit one Gy, assuming uniform irradiation:  
 $\approx$  (charged particles)  $6.24 \times 10^9 / (dE/dx)$ , where  $dE/dx$  (MeV  $\text{g}^{-1} \text{ cm}^2$ ), the energy loss per unit length, may be obtained from Figs. 33.2 and 33.4 in Sec. 33 of the *Review*, and [pdg.lbl.gov/AtomicNuclearProperties](http://pdg.lbl.gov/AtomicNuclearProperties).

$\approx 3.5 \times 10^9 \text{ cm}^{-2}$  minimum-ionizing singly-charged particles in carbon.

$\approx$  (photons)  $6.24 \times 10^9 / [Ef/\ell]$ , for photons of energy  $E$  (MeV), attenuation length  $\ell$  ( $\text{g cm}^{-2}$ ), and fraction  $f \lesssim 1$  expressing the fraction of the photon’s energy deposited in a small volume of thickness  $\ll \ell$  but large enough to contain the secondary electrons.

$\approx 2 \times 10^{11}$  photons  $\text{cm}^{-2}$  for 1 MeV photons on carbon ( $f \approx 1/2$ ).

### 36.3. Health effects of ionizing radiation

- **Recommended limits of effective dose to radiation workers (whole-body dose):\***

EU/Switzerland: 20 mSv  $\text{yr}^{-1}$

U.S.: 50 mSv  $\text{yr}^{-1}$  (5 rem  $\text{yr}^{-1}$ )†

- **Lethal dose:** The whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) is 2.5–4.5 Gy (250–450 rad), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

- **Cancer induction by low LET radiation:** The cancer induction probability is about 5% per Sv on average for the entire population [2].

#### Footnotes:

\* The ICRP recommendation [2] is 20 mSv  $\text{yr}^{-1}$  averaged over 5 years, with the dose in any one year  $\leq 50$  mSv.

† Many laboratories in the U.S. and elsewhere set lower limits.

## 37. Commonly Used Radioactive Sources

**Table 37.1.** Revised August 2017 by D.E. Groom (LBNL) and R.B. Firestone (LBNL).

Nuclide	Half-life	Type of decay	Particle		Photon

		Fission (3.1%):	Average 7.8 $\gamma$ 's/fission; $\langle E_\gamma \rangle = 0.88$ MeV $\approx 4$ neutrons/fission; $\langle E_n \rangle = 2.14$ MeV			

“Emission probability” is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and  $e^-$  means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV  $e^+e^-$  annihilation photons depends upon the number of stopped positrons. Endpoint  $\beta^\pm$  energies are listed. In some cases when energies are closely spaced, the  $\gamma$ -ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities may be found in [www-pub.iaea.org/books/IAEABooks/7551/Update-of-X-Ray-and-Gamma-Ray-Decay-Data-Standards-for-Detector-Calibration-and-Other-Applications](http://www-pub.iaea.org/books/IAEABooks/7551/Update-of-X-Ray-and-Gamma-Ray-Decay-Data-Standards-for-Detector-Calibration-and-Other-Applications), IAEA (2007) or Nuclear Data Sheets

([www.journals.elsevier.com/nuclear-data-sheets](http://www.journals.elsevier.com/nuclear-data-sheets)) (2007).

Neutron sources: See e.g. “Neutron Calibration Sources in the Daya Bay Experiment,” J. Liu *et al.*, Nuclear Instrum. Methods **A797**, 260 (2005) (arXiv.1504.07911).

$^{51}_{24}\text{Cr}$  calibration of neutrino detectors is discussed in e.g. J.N. Abdurashitov *et al.* [SAGE Collaboration], Phys. Rev. **C59**, 2246 (1999). The use of  $^{75}_{34}\text{Se}$  and other isotopes has been proposed.

## 38. PROBABILITY

Revised September 2015 by G. Cowan (RHUL).

The following is a much-shortened version of Sec. 38 of the full *Review*. Equation, section, and figure numbers follow the *Review*.

### 38.2. Random variables

- *Probability density function* (p.d.f.):  $x$  is a *random variable*.

Continuous:  $f(x; \theta)dx$  = probability  $x$  is between  $x$  to  $x + dx$ , given parameter(s)  $\theta$ ;

Discrete:  $f(x; \theta)$  = probability of  $x$  given  $\theta$ .

- *Cumulative distribution function*:

$$F(a) = \int_{-\infty}^a f(x) dx . \quad (38.6)$$

Here and below, if  $x$  is discrete-valued, the integral is replaced by a sum. The endpoint  $a$  is included in the integral or sum.

- *Expectation values*: Given a function  $u$ :

$$E[u(x)] = \int_{-\infty}^{\infty} u(x) f(x) dx . \quad (38.7)$$

- *Moments*:

$n$ th moment of a random variable:  $\alpha_n = E[x^n]$  , (38.8a)

$n$ th central moment:  $m_n = E[(x - \alpha_1)^n]$  . (38.8b)

Mean:  $\mu \equiv \alpha_1$  . (38.9a)

Variance:  $\sigma^2 \equiv V[x] \equiv m_2 = \alpha_2 - \mu^2$  . (38.9b)

Coefficient of skewness:  $\gamma_1 \equiv m_3/\sigma^3$ .

Kurtosis:  $\gamma_2 = m_4/\sigma^4 - 3$ .

Median:  $F(x_{\text{med}}) = 1/2$ .

- *Marginal p.d.f.*: Let  $x, y$  be two random variables with joint p.d.f.  $f(x, y)$ .

$$f_1(x) = \int_{-\infty}^{\infty} f(x, y) dy ; \quad f_2(y) = \int_{-\infty}^{\infty} f(x, y) dx . \quad (38.10)$$

- *Conditional p.d.f.:*

$$f_4(x|y) = f(x, y)/f_2(y) ; \quad f_3(y|x) = f(x, y)/f_1(x) .$$

- *Bayes' theorem*:

$$f_4(x|y) = \frac{f_3(y|x)f_1(x)}{f_2(y)} = \frac{f_3(y|x)f_1(x)}{\int f_3(y|x')f_1(x') dx'} . \quad (38.11)$$

- *Correlation coefficient and covariance*:

$$\mu_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} xf(x, y) dx dy , \quad (38.12)$$

$$\rho_{xy} = E [(x - \mu_x)(y - \mu_y)] / \sigma_x \sigma_y \equiv \text{cov}[x, y]/\sigma_x \sigma_y ,$$

$$\sigma_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \mu_x)^2 f(x, y) dx dy . \text{ Note } \rho_{xy}^2 \leq 1.$$

- *Independence:*  $x, y$  are independent if and only if  $f(x, y) = f_1(x) \cdot f_2(y)$ ; then  $\rho_{xy} = 0$ ,  $E[u(x)v(y)] = E[u(x)]E[v(y)]$  and  $V[x+y] = V[x] + V[y]$ .

- *Change of variables:* From  $\mathbf{x} = (x_1, \dots, x_n)$  to  $\mathbf{y} = (y_1, \dots, y_n)$ :  $g(\mathbf{y}) = f(\mathbf{x}(\mathbf{y})) \cdot |J|$  where  $|J|$  is the absolute value of the determinant of the Jacobian  $J_{ij} = \partial x_i / \partial y_j$ . For discrete variables, use  $|J| = 1$ .

### 38.3. Characteristic functions

Given a pdf  $f(x)$  for a continuous random variable  $x$ , the characteristic function  $\phi(u)$  is given by (31.6). Its derivatives are related to the algebraic moments of  $x$  by (31.7).

$$\phi(u) = E[e^{iux}] = \int_{-\infty}^{\infty} e^{iux} f(x) dx . \quad (38.17)$$

$$i^{-n} \left. \frac{d^n \phi}{du^n} \right|_{u=0} = \int_{-\infty}^{\infty} x^n f(x) dx = \alpha_n . \quad (38.18)$$

If the p.d.f.s  $f_1(x)$  and  $f_2(y)$  for independent random variables  $x$  and  $y$  have characteristic functions  $\phi_1(u)$  and  $\phi_2(u)$ , then the characteristic function of the weighted sum  $ax + by$  is  $\phi_1(au)\phi_2(bu)$ . The additional rules for several important distributions (*e.g.*, that the sum of two Gaussian distributed variables also follows a Gaussian distribution) easily follow from this observation.

### 38.4. Some probability distributions

See Table 38.1.

#### 38.4.2. Poisson distribution :

The Poisson distribution  $f(n; \nu)$  gives the probability of finding exactly  $n$  events in a given interval of  $x$  (*e.g.*, space or time) when the events occur independently of one another and of  $x$  at an average rate of  $\nu$  per the given interval. The variance  $\sigma^2$  equals  $\nu$ . It is the limiting case  $p \rightarrow 0$ ,  $N \rightarrow \infty$ ,  $Np = \nu$  of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large  $\nu$ .

#### 38.4.3. Normal or Gaussian distribution :

Its cumulative distribution, for mean 0 and variance 1, is often tabulated as the *error function*

$$F(x; 0, 1) = \frac{1}{2} \left[ 1 + \operatorname{erf}(x/\sqrt{2}) \right] . \quad (38.24)$$

For mean  $\mu$  and variance  $\sigma^2$ , replace  $x$  by  $(x - \mu)/\sigma$ .

$P(x \text{ in range } \mu \pm \sigma) = 0.6827$ ,

$P(x \text{ in range } \mu \pm 0.6745\sigma) = 0.5$ ,

$E[|x - \mu|] = \sqrt{2/\pi}\sigma = 0.7979\sigma$ ,

half-width at half maximum =  $\sqrt{2 \ln 2} \cdot \sigma = 1.177\sigma$ .

**Table 38.1.** Some common probability density functions, with corresponding characteristic functions and means and variances. In the Table,  $\Gamma(k)$  is the gamma function, equal to  $(k-1)!$  when  $k$  is an integer.

Distribution	Probability density function $f$ (variable; parameters)	Characteristic function $\phi(u)$	Mean	Variance $\sigma^2$
Uniform	$f(x; a, b) = \begin{cases} 1/(b-a) & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$	$\frac{e^{ibu} - e^{iau}}{(b-a)iu}$	$\frac{a+b}{2}$	$\frac{(b-a)^2}{12}$
Binomial	$f(r; N, p) = \frac{N!}{r!(N-r)!} p^r q^{N-r}$ $r = 0, 1, 2, \dots, N ; \quad 0 \leq p \leq 1 ; \quad q = 1 - p$	$(q + pe^{iu})^N$	$Np$	$Npq$
Poisson	$f(n; \nu) = \frac{\nu^n e^{-\nu}}{n!} ; \quad n = 0, 1, 2, \dots ; \quad \nu > 0$	$\exp[\nu(e^{iu} - 1)]$	$\nu$	$\nu$
Normal (Gaussian)	$f(x; \mu, \sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} \exp(-(x-\mu)^2/2\sigma^2)$ $-\infty < x < \infty ; \quad -\infty < \mu < \infty ; \quad \sigma > 0$	$\exp(i\mu u - \frac{1}{2}\sigma^2 u^2)$	$\mu$	$\sigma^2$
Multivariate Gaussian	$f(\mathbf{x}; \boldsymbol{\mu}, V) = \frac{1}{(2\pi)^{n/2} \sqrt{ V }}$ $\times \exp[-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu})^T V^{-1} (\mathbf{x} - \boldsymbol{\mu})]$ $-\infty < x_j < \infty ; \quad -\infty < \mu_j < \infty ; \quad  V  > 0$	$\exp[i\boldsymbol{\mu} \cdot \mathbf{u} - \frac{1}{2}\mathbf{u}^T V \mathbf{u}]$	$\boldsymbol{\mu}$	$V_{jk}$
$\chi^2$	$f(z; n) = \frac{z^{n/2-1} e^{-z/2}}{2^{n/2} \Gamma(n/2)} ; \quad z \geq 0$	$(1 - 2iu)^{-n/2}$	$n$	$2n$
Student's $t$	$f(t; n) = \frac{1}{\sqrt{n\pi}} \frac{\Gamma[(n+1)/2]}{\Gamma(n/2)} \left(1 + \frac{t^2}{n}\right)^{-(n+1)/2}$ $-\infty < t < \infty ; \quad n$ not required to be integer	—	0	$n/(n-2)$ for $n > 2$
Gamma	$f(x; \lambda, k) = \frac{x^{k-1} \lambda^k e^{-\lambda x}}{\Gamma(k)} ; \quad 0 \leq x < \infty ;$ $k$ not required to be integer	$(1 - iu/\lambda)^{-k}$	$k/\lambda$	$k/\lambda^2$

For  $n$  Gaussian random variables  $\mathbf{x}_i$ , the joint p.d.f. is the multivariate Gaussian:

$$f(\mathbf{x}; \boldsymbol{\mu}, V) = \frac{1}{(2\pi)^{n/2} \sqrt{|V|}} \exp \left[ -\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^T V^{-1} (\mathbf{x} - \boldsymbol{\mu}) \right], \quad |V| > 0. \quad (38.25)$$

$V$  is the  $n \times n$  covariance matrix;  $V_{ij} \equiv E[(x_i - \mu_i)(x_j - \mu_j)] \equiv \rho_{ij} \sigma_i \sigma_j$ , and  $V_{ii} = V[x_i]$ ;  $|V|$  is the determinant of  $V$ . For  $n = 2$ ,  $f(\mathbf{x}; \boldsymbol{\mu}, V)$  is

$$f(x_1, x_2; \mu_1, \mu_2, \sigma_1, \sigma_2, \rho) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \times \exp \left\{ \frac{-1}{2(1-\rho^2)} \left[ \frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2} \right] \right\}. \quad (38.26)$$

The marginal distribution of any  $x_i$  is a Gaussian with mean  $\mu_i$  and variance  $V_{ii}$ .  $V$  is  $n \times n$ , symmetric, and positive definite. Therefore for any vector  $\mathbf{X}$ , the quadratic form  $\mathbf{X}^T V^{-1} \mathbf{X} = C$ , where  $C$  is any positive number, traces an  $n$ -dimensional ellipsoid as  $\mathbf{X}$  varies. If  $X_i = x_i - \mu_i$ , then  $C$  is a random variable obeying the  $\chi^2$  distribution with  $n$  degrees of freedom, discussed in the following section. The probability that  $\mathbf{X}$  corresponding to a set of Gaussian random variables  $x_i$  lies outside the ellipsoid characterized by a given value of  $C$  ( $= \chi^2$ ) is given by  $1 - F_{\chi^2}(C; n)$ , where  $F_{\chi^2}$  is the cumulative  $\chi^2$  distribution. This may be read from Fig. 39.1. For example, the “ $s$ -standard-deviation ellipsoid” occurs at  $C = s^2$ . For the two-variable case ( $n = 2$ ), the point  $\mathbf{X}$  lies outside the one-standard-deviation ellipsoid with 61% probability. The use of these ellipsoids as indicators of probable error is described in Sec. 39.4.2.2; the validity of those indicators assumes that  $\boldsymbol{\mu}$  and  $V$  are correct.

#### 38.4.5. $\chi^2$ distribution :

If  $x_1, \dots, x_n$  are independent Gaussian random variables, the sum  $z = \sum_{i=1}^n (x_i - \mu_i)^2 / \sigma_i^2$  follows the  $\chi^2$  p.d.f. with  $n$  degrees of freedom, which we denote by  $\chi^2(n)$ . More generally, for  $n$  correlated Gaussian variables as components of a vector  $\mathbf{X}$  with covariance matrix  $V$ ,  $z = \mathbf{X}^T V^{-1} \mathbf{X}$  follows  $\chi^2(n)$  as in the previous section. For a set of  $z_i$ , each of which follows  $\chi^2(n_i)$ ,  $\sum z_i$  follows  $\chi^2(\sum n_i)$ . For large  $n$ , the  $\chi^2$  p.d.f. approaches a Gaussian with mean  $\mu = n$  and variance  $\sigma^2 = 2n$ .

The  $\chi^2$  p.d.f. is often used in evaluating the level of compatibility between observed data and a hypothesis for the p.d.f. that the data might follow. This is discussed further in Sec. 39.3.2 on tests of goodness-of-fit.

#### 38.4.7. Gamma distribution :

For a process that generates events as a function of  $x$  (e.g., space or time) according to a Poisson distribution, the distance in  $x$  from an arbitrary starting point (which may be some particular event) to the  $k^{th}$  event follows a gamma distribution,  $f(x; \lambda, k)$ . The Poisson parameter  $\mu$  is  $\lambda$  per unit  $x$ . The special case  $k = 1$  (i.e.,  $f(x; \lambda, 1) = \lambda e^{-\lambda x}$ ) is called the exponential distribution. A sum of  $k'$  exponential random variables  $x_i$  is distributed as  $f(\sum x_i; \lambda, k')$ .

The parameter  $k$  is not required to be an integer. For  $\lambda = 1/2$  and  $k = n/2$ , the gamma distribution reduces to the  $\chi^2(n)$  distribution.

## 39. Statistics

Revised September 2017 by G. Cowan (RHUL).

This chapter gives an overview of statistical methods used in high-energy physics. In statistics, we are interested in using a given sample of data to make inferences about a probabilistic model, *e.g.*, to assess the model's validity or to determine the values of its parameters. There are two main approaches to statistical inference, which we may call frequentist and Bayesian.

### 39.2. Parameter estimation

An *estimator*  $\hat{\theta}$  (written with a hat) is a function of the data used to estimate the value of the parameter  $\theta$ .

#### 39.2.1. Estimators for mean, variance, and median :

Suppose we have a set of  $n$  independent measurements,  $x_1, \dots, x_n$ , each assumed to follow a p.d.f. with unknown mean  $\mu$  and unknown variance  $\sigma^2$  (the measurements do not necessarily have to follow a Gaussian distribution). Then

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^n x_i \quad (39.5)$$

$$\widehat{\sigma^2} = \frac{1}{n-1} \sum_{i=1}^n (x_i - \hat{\mu})^2 \quad (39.6)$$

are unbiased estimators of  $\mu$  and  $\sigma^2$ . The variance of  $\hat{\mu}$  is  $\sigma^2/n$  and the variance of  $\widehat{\sigma^2}$  is

$$V[\widehat{\sigma^2}] = \frac{1}{n} \left( m_4 - \frac{n-3}{n-1} \sigma^4 \right), \quad (39.7)$$

where  $m_4$  is the 4<sup>th</sup> central moment of  $x$  (see Eq. (38.8b)). For Gaussian distributed  $x_i$ , this becomes  $2\sigma^4/(n-1)$  for any  $n \geq 2$ , and for large  $n$  the standard deviation of  $\widehat{\sigma}$  is  $\sigma/\sqrt{2n}$ .

If the  $x_i$  have different, known variances  $\sigma_i^2$ , then the weighted average

$$\hat{\mu} = \frac{1}{w} \sum_{i=1}^n w_i x_i, \quad (39.8)$$

where  $w_i = 1/\sigma_i^2$  and  $w = \sum_i w_i$ , is an unbiased estimator for  $\mu$  with a smaller variance than an unweighted average. The standard deviation of  $\hat{\mu}$  is  $1/\sqrt{w}$ .

#### 39.2.2. The method of maximum likelihood :

Suppose we have a set of measured quantities  $\mathbf{x}$  and the likelihood  $L(\boldsymbol{\theta}) = P(\mathbf{x}|\boldsymbol{\theta})$  for a set of parameters  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_N)$ . The *maximum likelihood* (ML) estimators for  $\boldsymbol{\theta}$  can be found by solving the *likelihood equations*,

$$\frac{\partial \ln L}{\partial \theta_i} = 0, \quad i = 1, \dots, N. \quad (39.9)$$

In the large sample limit, the  $s$  times the standard deviations  $\sigma_i$  of the estimators for the parameters can be obtained from the hypersurface defined by the  $\boldsymbol{\theta}$  such that

$$\ln L(\boldsymbol{\theta}) = \ln L_{\max} - s^2/2, \quad (39.10)$$

### 39.2.3. The method of least squares :

For Gaussian distributed measurements  $y_i$  with mean  $\mu(x_i; \boldsymbol{\theta})$  and known variance  $\sigma_i^2$ , the log-likelihood function contains the sum of squares

$$\chi^2(\boldsymbol{\theta}) = -2 \ln L(\boldsymbol{\theta}) + \text{constant} = \sum_{i=1}^N \frac{(y_i - \mu(x_i; \boldsymbol{\theta}))^2}{\sigma_i^2}. \quad (39.19)$$

If the  $y_i$  have a covariance matrix  $V_{ij} = \text{cov}[y_i, y_j]$ , then the estimators are determined by the minimum of

$$\chi^2(\boldsymbol{\theta}) = (\mathbf{y} - \boldsymbol{\mu}(\boldsymbol{\theta}))^T V^{-1} (\mathbf{y} - \boldsymbol{\mu}(\boldsymbol{\theta})), \quad (39.20)$$

## 39.3. Statistical tests

### 39.3.1. Hypothesis tests :

A frequentist *test* of a hypothesis (often called the null hypothesis,  $H_0$ ) is a rule that states for which data values  $\mathbf{x}$  the hypothesis is rejected. A critical region  $w$  is specified such that there is no more than a given probability  $\alpha$ , called the *size* or *significance level* of the test, to find  $\mathbf{x} \in w$ . If the data are discrete, it may not be possible to find a critical region with exact probability content  $\alpha$ , and thus we require  $P(\mathbf{x} \in w | H_0) \leq \alpha$ . If the data are observed in the critical region,  $H_0$  is rejected.

The critical region is not unique, and generally defined relative to some alternative hypothesis (or set of alternatives)  $H_1$ . To maximize the power of the test of  $H_0$  with respect to the alternative  $H_1$ , the *Neyman–Pearson lemma* states that the critical region  $w$  should be chosen such that for all data values  $\mathbf{x}$  inside  $w$ , the likelihood ratio

$$\lambda(\mathbf{x}) = \frac{f(\mathbf{x}|H_1)}{f(\mathbf{x}|H_0)} \quad (39.44)$$

is greater than or equal to a given constant  $c_\alpha$ , and everywhere outside the critical region one has  $\lambda(\mathbf{x}) < c_\alpha$ , where the value of  $c_\alpha$  is determined by the size of the test  $\alpha$ . Here  $H_0$  and  $H_1$  must be simple hypotheses, i.e., they should not contain undetermined parameters.

### 39.3.2. Tests of significance (goodness-of-fit) :

Often one wants to quantify the level of agreement between the data and a hypothesis without explicit reference to alternative hypotheses. This can be done by defining a statistic  $t$  whose value reflects in some way the level of agreement between the data and the hypothesis. For example, if  $t$  is defined such that large values correspond to poor agreement with the hypothesis, then the *p-value* would be

$$p = \int_{t_{\text{obs}}}^{\infty} f(t|H_0) dt, \quad (39.45)$$

where  $t_{\text{obs}}$  is the value of the statistic obtained in the actual experiment.

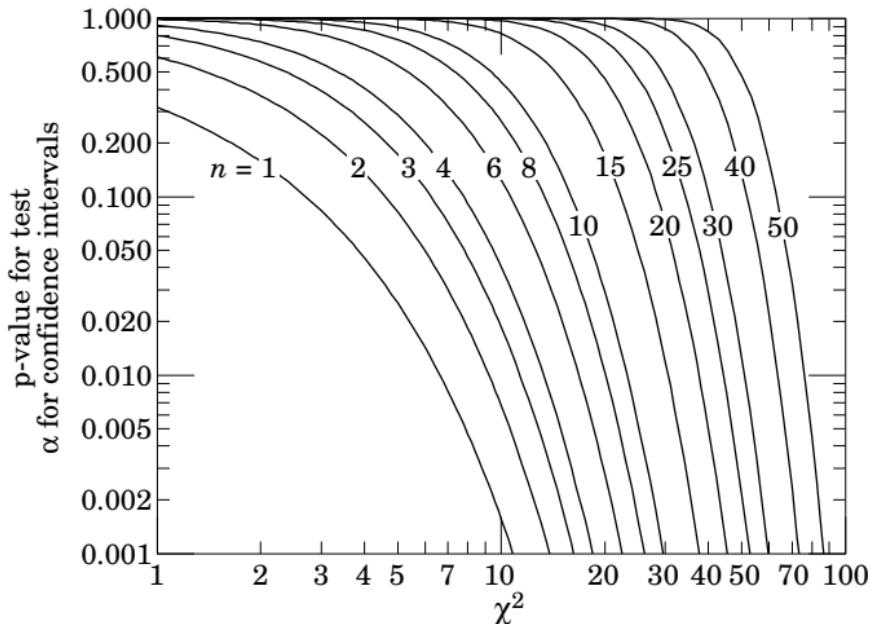

#### 39.3.2.1. Goodness-of-fit with the method of least squares:

For Poisson measurements  $n_i$  with variances  $\sigma_i^2 = \mu_i$ , the  $\chi^2$  (39.19) becomes *Pearson's  $\chi^2$  statistic*,

$$\chi^2 = \sum_{i=1}^N \frac{(n_i - \mu_i)^2}{\mu_i}. \quad (39.53)$$

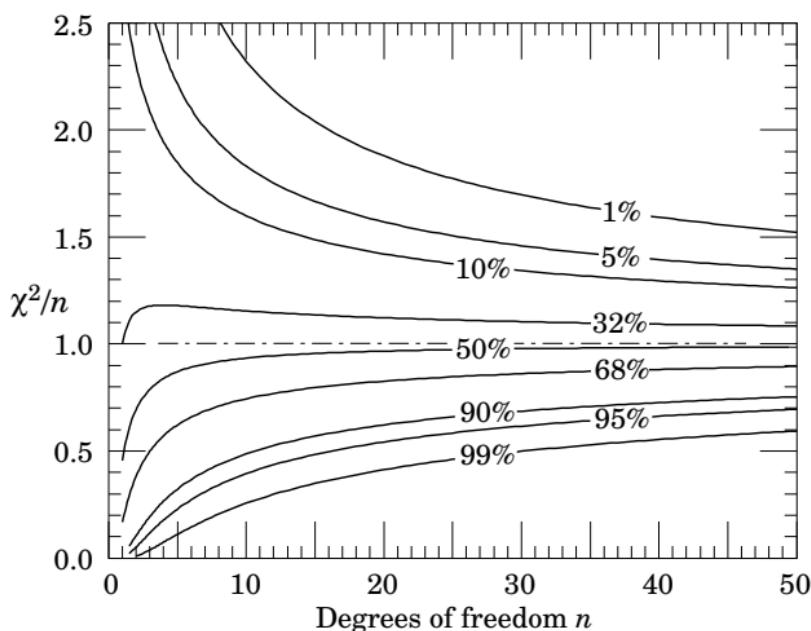

Assuming the goodness-of-fit statistic follows a  $\chi^2$  p.d.f., the *p-value* for the hypothesis is then

$$p = \int_{\chi^2}^{\infty} f(z; n_d) dz, \quad (39.54)$$

**Figure 39.1:** One minus the  $\chi^2$  cumulative distribution,  $1-F(\chi^2; n)$ , for  $n$  degrees of freedom. This gives the  $p$ -value for the  $\chi^2$  goodness-of-fit test as well as one minus the coverage probability for confidence regions (see Sec. 39.4.2.2).

where  $f(z; n_d)$  is the  $\chi^2$  p.d.f. and  $n_d$  is the appropriate number of degrees of freedom. Values are shown in Fig. 39.1. The  $p$ -values obtained for different values of  $\chi^2/n_d$  are shown in Fig. 39.2.

**Figure 39.2:** The ‘reduced’  $\chi^2$ , equal to  $\chi^2/n$ , for  $n$  degrees of freedom. The curves show as a function of  $n$  the  $\chi^2/n$  that corresponds to a given  $p$ -value.

### 39.3.3. Bayes factors :

In Bayesian statistics, one could reject a hypothesis  $H$  if its posterior probability  $P(H|\mathbf{x})$  is sufficiently small. The full prior probability for two models (hypotheses)  $H_i$  and  $H_j$  can be written in the form

$$\pi(H_i, \boldsymbol{\theta}_i) = P(H_i)\pi(\boldsymbol{\theta}_i|H_i). \quad (39.55)$$

The *Bayes factor* is defined as

$$B_{ij} = \frac{\int P(\mathbf{x}|\boldsymbol{\theta}_i, H_i)\pi(\boldsymbol{\theta}_i|H_i) d\boldsymbol{\theta}_i}{\int P(\mathbf{x}|\boldsymbol{\theta}_j, H_j)\pi(\boldsymbol{\theta}_j|H_j) d\boldsymbol{\theta}_j}. \quad (39.58)$$

This gives what the ratio of posterior probabilities for models  $i$  and  $j$  would be if the overall prior probabilities for the two models were equal.

## 39.4. Intervals and limits

### 39.4.1. Bayesian intervals :

A Bayesian or credible interval)  $[\theta_{lo}, \theta_{up}]$  can be determined which contains a given fraction  $1 - \alpha$  of the posterior probability, i.e.,

$$1 - \alpha = \int_{\theta_{lo}}^{\theta_{up}} p(\theta|\mathbf{x}) d\theta. \quad (39.60)$$

### 39.4.2. Frequentist confidence intervals :

#### 39.4.2.1. The Neyman construction for confidence intervals:

Given a p.d.f.  $f(x;\theta)$ , we can find using a pre-defined rule and probability  $1 - \alpha$  for every value of  $\theta$ , a set of values  $x_1(\theta, \alpha)$  and  $x_2(\theta, \alpha)$  such that

$$P(x_1 < x < x_2; \theta) = \int_{x_1}^{x_2} f(x; \theta) dx \geq 1 - \alpha. \quad (39.67)$$

#### 39.4.2.2. Gaussian distributed measurements:

When the data consists of a single random variable  $x$  that follows a Gaussian distribution with known  $\sigma$ , the probability that the measured value  $x$  will fall within  $\pm\delta$  of the true value  $\mu$  is

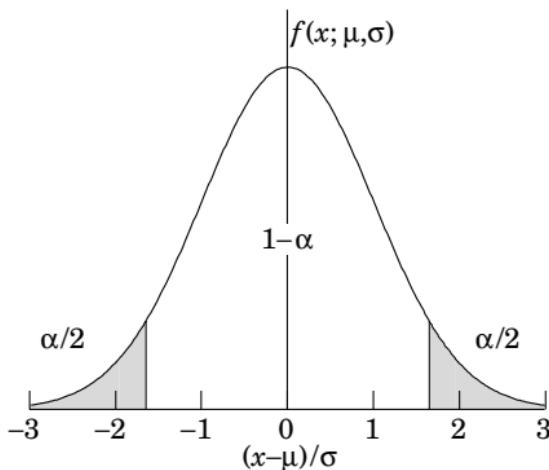

$$1 - \alpha = \frac{1}{\sqrt{2\pi}\sigma} \int_{\mu-\delta}^{\mu+\delta} e^{-(x-\mu)^2/2\sigma^2} dx = \text{erf}\left(\frac{\delta}{\sqrt{2}\sigma}\right) = 2\Phi\left(\frac{\delta}{\sigma}\right) - 1, \quad (39.70)$$

Fig. 39.4 shows a  $\delta = 1.64\sigma$  confidence interval unshaded. Values of  $\alpha$  for other frequently used choices of  $\delta$  are given in Table 39.1.

**Table 39.1:** Area of the tails  $\alpha$  outside  $\pm\delta$  from the mean of a Gaussian distribution.

$\alpha$	$\delta$	$\alpha$	$\delta$
0.3173	$1\sigma$	0.2	$1.28\sigma$
$4.55 \times 10^{-2}$	$2\sigma$	0.1	$1.64\sigma$
$2.7 \times 10^{-3}$	$3\sigma$	0.05	$1.96\sigma$
$6.3 \times 10^{-5}$	$4\sigma$	0.01	$2.58\sigma$
$5.7 \times 10^{-7}$	$5\sigma$	0.001	$3.29\sigma$
$2.0 \times 10^{-9}$	$6\sigma$	$10^{-4}$	$3.89\sigma$

We can set a one-sided (upper or lower) limit by excluding above  $x + \delta$  (or below  $x - \delta$ ). The values of  $\alpha$  for such limits are half the values in Table 39.1. Values of  $\Delta\chi^2$  or  $2\Delta\ln L$  are given in Table 39.2 for several values of the coverage probability  $1 - \alpha$  and number of fitted parameters  $m$ .

**Figure 39.4:** Illustration of a symmetric 90% confidence interval (unshaded) for a Gaussian-distributed measurement of a single quantity. Integrated probabilities, defined by  $\alpha = 0.1$ , are as shown.

**Table 39.2:** Values of  $\Delta\chi^2$  or  $2\Delta \ln L$  corresponding to a coverage probability  $1 - \alpha$  in the large data sample limit, for joint estimation of  $m$  parameters.

$(1 - \alpha)$ (%)	$m = 1$	$m = 2$	$m = 3$
68.27	1.00	2.30	3.53
90.	2.71	4.61	6.25
95.	3.84	5.99	7.82
95.45	4.00	6.18	8.03
99.	6.63	9.21	11.34
99.73	9.00	11.83	14.16

### 39.4.2.3. Poisson or binomial data:

For Poisson distributed  $n$ , the upper and lower limits on the mean value  $\mu$  from the Neyman procedure are

$$\mu_{\text{lo}} = \frac{1}{2} F_{\chi^2}^{-1}(\alpha_{\text{lo}}; 2n), \quad (39.76a)$$

$$\mu_{\text{up}} = \frac{1}{2} F_{\chi^2}^{-1}(1 - \alpha_{\text{up}}; 2(n + 1)), \quad (39.76b)$$

For the case of binomially distributed  $n$  successes out of  $N$  trials with probability of success  $p$ , the upper and lower limits on  $p$  are found to be

$$p_{\text{lo}} = \frac{n F_F^{-1}[\alpha_{\text{lo}}; 2n, 2(N - n + 1)]}{N - n + 1 + n F_F^{-1}[\alpha_{\text{lo}}; 2n, 2(N - n + 1)]}, \quad (39.77a)$$

$$p_{\text{up}} = \frac{(n + 1) F_F^{-1}[1 - \alpha_{\text{up}}; 2(n + 1), 2(N - n)]}{(N - n) + (n + 1) F_F^{-1}[1 - \alpha_{\text{up}}; 2(n + 1), 2(N - n)]}. \quad (39.77b)$$

Here  $F_F^{-1}$  is the quantile of the  $F$  distribution (also called the Fisher–Snedecor distribution; see Ref. [4]).

Several problems with such intervals are overcome by using the unified approach of Feldman and Cousins [38]. Properties of these intervals are described further in the *Review*. Table 39.4 gives the unified confidence intervals  $[\mu_1, \mu_2]$  for the mean of a Poisson variable given  $n$  observed

**Table 39.3:** Lower and upper (one-sided) limits for the mean  $\mu$  of a Poisson variable given  $n$  observed events in the absence of background, for confidence levels of 90% and 95%.

$n$	$1 - \alpha = 90\%$		$1 - \alpha = 95\%$	
	$\mu_{\text{lo}}$	$\mu_{\text{up}}$	$\mu_{\text{lo}}$	$\mu_{\text{up}}$
0	—	2.30	—	3.00
1	0.105	3.89	0.051	4.74
2	0.532	5.32	0.355	6.30
3	1.10	6.68	0.818	7.75
4	1.74	7.99	1.37	9.15
5	2.43	9.27	1.97	10.51
6	3.15	10.53	2.61	11.84
7	3.89	11.77	3.29	13.15
8	4.66	12.99	3.98	14.43
9	5.43	14.21	4.70	15.71
10	6.22	15.41	5.43	16.96

events in the absence of background, for confidence levels of 90% and 95%.

**Table 39.4:** Unified confidence intervals  $[\mu_1, \mu_2]$  for the mean of a Poisson variable given  $n$  observed events in the absence of background, for confidence levels of 90% and 95%.

$n$	$1 - \alpha = 90\%$		$1 - \alpha = 95\%$	
	$\mu_1$	$\mu_2$	$\mu_1$	$\mu_2$
0	0.00	2.44	0.00	3.09
1	0.11	4.36	0.05	5.14
2	0.53	5.91	0.36	6.72

5	1.84	9.99	1.84	11.26
6	2.21	11.47	2.21	12.75
7	3.56	12.53	2.58	13.81
8	3.96	13.99	2.94	15.29
9	4.36	15.30	4.36	16.77
10	5.50	16.50	4.75	17.82

## 44. Clebsch-Gordan Coefficients, Spherical Harmonics, and $d$ Functions

Note: A square-root sign is to be understood over *every* coefficient, e.g., for  $-8/15$  read  $-\sqrt{8/15}$ .

$$\begin{aligned}
d_{m,0}^j &= (-1)^{m-m'} d_{m,m'}^j = d_{-m,-m'}^j \\
d_{m',m}^j &= \sqrt{\frac{4\pi}{2\ell+1}} Y_\ell^m e^{-im\phi} \\
d_{m',m}^{\ell} &= \sqrt{\frac{4\pi}{2\ell+1}} Y_\ell^m e^{-im\phi}
\end{aligned}$$

## 47. Kinematics

Revised August 2017 by D.R. Tovey (Sheffield) and January 2000 by J.D. Jackson (LBNL).

Throughout this section units are used in which  $\hbar = c = 1$ . The following conversions are useful:  $\hbar c = 197.3 \text{ MeV fm}$ ,  $(\hbar c)^2 = 0.3894 (\text{GeV})^2 \text{ mb}$ .

### 47.1. Lorentz transformations

The energy  $E$  and 3-momentum  $\mathbf{p}$  of a particle of mass  $m$  form a 4-vector  $p = (E, \mathbf{p})$  whose square  $p^2 \equiv E^2 - |\mathbf{p}|^2 = m^2$ . The velocity of the particle is  $\beta = \mathbf{p}/E$ . The energy and momentum  $(E^*, \mathbf{p}^*)$  viewed from a frame moving with velocity  $\beta_f$  are given by

$$\begin{pmatrix} E^* \\ p_{\parallel}^* \end{pmatrix} = \begin{pmatrix} \gamma_f & -\gamma_f \beta_f \\ -\gamma_f \beta_f & \gamma_f \end{pmatrix} \begin{pmatrix} E \\ p_{\parallel} \end{pmatrix}, \quad p_T^* = p_T, \quad (47.1)$$

where  $\gamma_f = (1 - \beta_f^2)^{-1/2}$  and  $p_T$  ( $p_{\parallel}$ ) are the components of  $\mathbf{p}$  perpendicular (parallel) to  $\beta_f$ . Other 4-vectors, such as the space-time coordinates of events, of course transform in the same way. The scalar product of two 4-momenta  $p_1 \cdot p_2 = E_1 E_2 - \mathbf{p}_1 \cdot \mathbf{p}_2$  is invariant (frame independent).

### 47.2. Center-of-mass energy and momentum

In the collision of two particles of masses  $m_1$  and  $m_2$  the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$\begin{aligned} E_{\text{cm}} &= \left[ (E_1 + E_2)^2 - (\mathbf{p}_1 + \mathbf{p}_2)^2 \right]^{1/2}, \\ &= \left[ m_1^2 + m_2^2 + 2E_1 E_2 (1 - \beta_1 \beta_2 \cos \theta) \right]^{1/2}, \end{aligned} \quad (47.2)$$

where  $\theta$  is the angle between the particles. In the frame where one particle (of mass  $m_2$ ) is at rest (lab frame),

$$E_{\text{cm}} = (m_1^2 + m_2^2 + 2E_1 \text{lab} m_2)^{1/2}. \quad (47.3)$$

The velocity of the center-of-mass in the lab frame is

$$\beta_{\text{cm}} = \mathbf{p}_{\text{lab}} / (E_1 \text{lab} + m_2), \quad (47.4)$$

where  $\mathbf{p}_{\text{lab}} \equiv \mathbf{p}_1 \text{lab}$  and

$$\gamma_{\text{cm}} = (E_1 \text{lab} + m_2) / E_{\text{cm}}. \quad (47.5)$$

The c.m. momenta of particles 1 and 2 are of magnitude

$$p_{\text{cm}} = p_{\text{lab}} \frac{m_2}{E_{\text{cm}}}. \quad (47.6)$$

For example, if a 0.80 GeV/c kaon beam is incident on a proton target, the center of mass energy is 1.699 GeV and the center of mass momentum of either particle is 0.442 GeV/c. It is also useful to note that

$$E_{\text{cm}} dE_{\text{cm}} = m_2 dE_1 \text{lab} = m_2 \beta_1 \text{lab} dp_{\text{lab}}. \quad (47.7)$$

### 47.3. Lorentz-invariant amplitudes

The matrix elements for a scattering or decay process are written in terms of an invariant amplitude  $-i\mathcal{M}$ . As an example, the  $S$ -matrix for  $2 \rightarrow 2$  scattering is related to  $\mathcal{M}$  by

$$\begin{aligned} \langle p'_1 p'_2 | S | p_1 p_2 \rangle &= I - i(2\pi)^4 \delta^4(p_1 + p_2 - p'_1 - p'_2) \\ &\times \frac{\mathcal{M}(p_1, p_2; p'_1, p'_2)}{(2E_1)^{1/2} (2E_2)^{1/2} (2E'_1)^{1/2} (2E'_2)^{1/2}}. \end{aligned} \quad (47.8)$$

The state normalization is such that

$$\langle p' | p \rangle = (2\pi)^3 \delta^3(\mathbf{p} - \mathbf{p}') . \quad (47.9)$$

#### 47.4. Particle decays

The partial decay rate of a particle of mass  $M$  into  $n$  bodies in its rest frame is given in terms of the Lorentz-invariant matrix element  $\mathcal{M}$  by

$$d\Gamma = \frac{(2\pi)^4}{2M} |\mathcal{M}|^2 d\Phi_n(P; p_1, \dots, p_n), \quad (47.11)$$

where  $d\Phi_n$  is an element of  $n$ -body phase space given by

$$d\Phi_n(P; p_1, \dots, p_n) = \delta^4(P - \sum_{i=1}^n p_i) \prod_{i=1}^n \frac{d^3 p_i}{(2\pi)^3 2E_i} . \quad (47.12)$$

This phase space can be generated recursively, viz.

$$\begin{aligned} d\Phi_n(P; p_1, \dots, p_n) &= d\Phi_j(q; p_1, \dots, p_j) \\ &\times d\Phi_{n-j+1}(P; q, p_{j+1}, \dots, p_n)(2\pi)^3 dq^2 , \end{aligned} \quad (47.13)$$

where  $q^2 = (\sum_{i=1}^j E_i)^2 - \left| \sum_{i=1}^j \mathbf{p}_i \right|^2$ . This form is particularly useful in the case where a particle decays into another particle that subsequently decays.

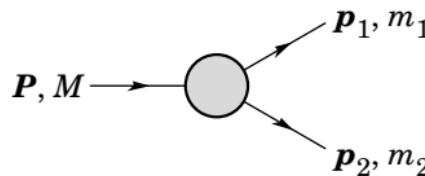

**47.4.1. Survival probability :** If a particle of mass  $M$  has mean proper lifetime  $\tau (= 1/\Gamma)$  and has momentum  $(E, \mathbf{p})$ , then the probability that it lives for a time  $t_0$  or greater before decaying is given by

$$P(t_0) = e^{-t_0 \Gamma/\gamma} = e^{-Mt_0 \Gamma/E} , \quad (47.14)$$

and the probability that it travels a distance  $x_0$  or greater is

$$P(x_0) = e^{-Mx_0 \Gamma/|\mathbf{p}|} . \quad (47.15)$$

#### 47.4.2. Two-body decays :

**Figure 47.1:** Definitions of variables for two-body decays.

In the rest frame of a particle of mass  $M$ , decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M} , \quad (47.16)$$

$$|\mathbf{p}_1| = |\mathbf{p}_2|$$

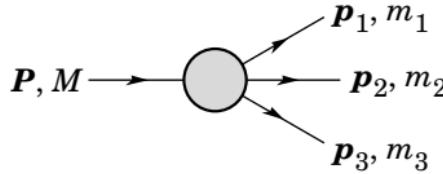

$$= \frac{\left[ (M^2 - (m_1 + m_2)^2) (M^2 - (m_1 - m_2)^2) \right]^{1/2}}{2M} , \quad (47.17)$$

and

$$d\Gamma = \frac{1}{32\pi^2} |\mathcal{M}|^2 \frac{|\mathbf{p}_1|}{M^2} d\Omega , \quad (47.18)$$

where  $d\Omega = d\phi_1 d(\cos \theta_1)$  is the solid angle of particle 1. The invariant mass  $M$  can be determined from the energies and momenta using Eq. (47.2) with  $M = E_{\text{cm}}$ .

#### 47.4.3. Three-body decays :

**Figure 47.2:** Definitions of variables for three-body decays.

Defining  $p_{ij} = p_i + p_j$  and  $m_{ij}^2 = p_{ij}^2$ , then  $m_{12}^2 + m_{23}^2 + m_{13}^2 = M^2 + m_1^2 + m_2^2 + m_3^2$  and  $m_{12}^2 = (P - p_3)^2 = M^2 + m_3^2 - 2ME_3$ , where  $E_3$  is the energy of particle 3 in the rest frame of  $M$ . In that frame, the momenta of the three decay particles lie in a plane. The relative orientation of these three momenta is fixed if their energies are known. The momenta can therefore be specified in space by giving three Euler angles  $(\alpha, \beta, \gamma)$  that specify the orientation of the final system relative to the initial particle. The direction of any one of the particles relative to the frame in which the initial particle is described can be specified in space by two angles  $(\alpha, \beta)$  while a third angle,  $\gamma$ , can be set as the azimuthal angle of a second particle around the first [1]. Then

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M} |\mathcal{M}|^2 dE_1 dE_3 d\alpha d(\cos \beta) d\gamma . \quad (47.19)$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M^2} |\mathcal{M}|^2 |\mathbf{p}_1^*| |\mathbf{p}_3| dm_{12} d\Omega_1^* d\Omega_3 , \quad (47.20)$$

where  $(|\mathbf{p}_1^*|, \Omega_1^*)$  is the momentum of particle 1 in the rest frame of 1 and 2, and  $\Omega_3$  is the angle of particle 3 in the rest frame of the decaying particle.  $|\mathbf{p}_1^*|$  and  $|\mathbf{p}_3|$  are given by

$$|\mathbf{p}_1^*| = \frac{[(m_{12}^2 - (m_1 + m_2)^2)(m_{12}^2 - (m_1 - m_2)^2)]^{1/2}}{2m_{12}} , \quad (47.21a)$$

and

$$|\mathbf{p}_3| = \frac{[(M^2 - (m_{12} + m_3)^2)(M^2 - (m_{12} - m_3)^2)]^{1/2}}{2M} . \quad (47.21b)$$

[Compare with Eq. (47.17).]

If the decaying particle is a scalar or we average over its spin states, then integration over the angles in Eq. (47.19) gives

$$\begin{aligned} d\Gamma &= \frac{1}{(2\pi)^3} \frac{1}{8M} \overline{|\mathcal{M}|^2} dE_1 dE_3 \\ &= \frac{1}{(2\pi)^3} \frac{1}{32M^3} \overline{|\mathcal{M}|^2} dm_{12}^2 dm_{23}^2 . \end{aligned} \quad (47.22)$$

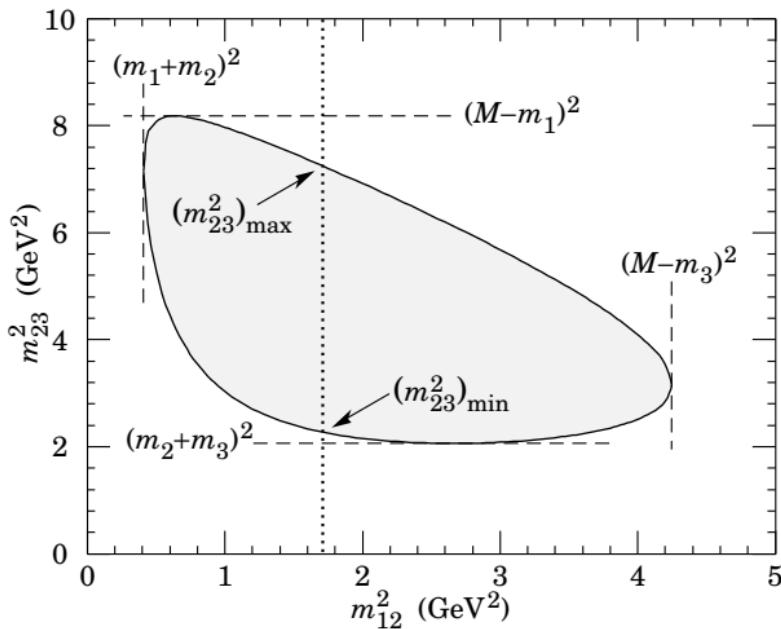

This is the standard form for the Dalitz plot.

**47.4.3.1. Dalitz plot:** For a given value of  $m_{12}^2$ , the range of  $m_{23}^2$  is determined by its values when  $\mathbf{p}_2$  is parallel or antiparallel to  $\mathbf{p}_3$ :

$$(m_{23}^2)_{\max} = (E_2^* + E_3^*)^2 - \left( \sqrt{E_2^{*2} - m_2^2} - \sqrt{E_3^{*2} - m_3^2} \right)^2, \quad (47.23a)$$

$$(m_{23}^2)_{\min} = (E_2^* + E_3^*)^2 - \left( \sqrt{E_2^{*2} - m_2^2} + \sqrt{E_3^{*2} - m_3^2} \right)^2. \quad (47.23b)$$

Here  $E_2^* = (m_{12}^2 - m_1^2 + m_2^2)/2m_{12}$  and  $E_3^* = (M^2 - m_{12}^2 - m_3^2)/2m_{12}$  are the energies of particles 2 and 3 in the  $m_{12}$  rest frame. The scatter plot in  $m_{12}^2$  and  $m_{23}^2$  is called a Dalitz plot. If  $|\mathcal{M}|^2$  is constant, the allowed region of the plot will be uniformly populated with events [see Eq. (47.22)]. A nonuniformity in the plot gives immediate information on  $|\mathcal{M}|^2$ . For example, in the case of  $D \rightarrow K\pi\pi$ , bands appear when  $m_{(K\pi)} = m_{K^*(892)}$ , reflecting the appearance of the decay chain  $D \rightarrow K^*(892)\pi \rightarrow K\pi\pi$ .

**Figure 47.3:** Dalitz plot for a three-body final state. In this example, the state is  $\pi^+ \bar{K}^0 p$  at 3 GeV. Four-momentum conservation restricts events to the shaded region.

#### 47.4.4. Kinematic limits :

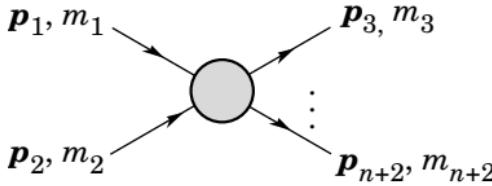

**47.4.4.1. Three-body decays:** In a three-body decay (Fig. 47.2) the maximum of  $|\mathbf{p}_3|$ , [given by Eq. (47.21)], is achieved when  $m_{12} = m_1 + m_2$ , i.e., particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition,  $m_3 > m_1, m_2$ , then  $|\mathbf{p}_3|_{\max} > |\mathbf{p}_1|_{\max}, |\mathbf{p}_2|_{\max}$ . The distribution of  $m_{12}$  values possesses an end-point or maximum value at  $m_{12} = M - m_3$ . This can be used to constrain the mass difference of a parent particle and one invisible decay product.

**47.4.5. Multibody decays :** The above results may be generalized to final states containing any number of particles by combining some of the particles into “effective particles” and treating the final states as 2 or 3 “effective particle” states. Thus, if  $p_{ijk\dots} = p_i + p_j + p_k + \dots$ , then

$$m_{ijk\dots} = \sqrt{p_{ijk\dots}^2}, \quad (47.26)$$

and  $m_{ijk\dots}$  may be used in place of *e.g.*,  $m_{12}$  in the relations in Sec. 47.4.3 or Sec. 47.4.4 above.

## 47.5. Cross sections

**Figure 47.5:** Definitions of variables for production of an  $n$ -body final state.

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4 |\mathcal{M}|^2}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}} \times d\Phi_n(p_1 + p_2; p_3, \dots, p_{n+2}). \quad (47.27)$$

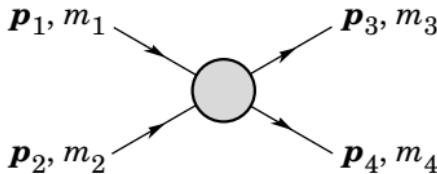

[See Eq. (47.12).] In the rest frame of  $m_2$ (lab),

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = m_2 p_{1\text{lab}}; \quad (47.28a)$$

while in the center-of-mass frame

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = p_{1\text{cm}} \sqrt{s}. \quad (47.28b)$$

### 47.5.1. Two-body reactions :

**Figure 47.6:** Definitions of variables for a two-body final state.

Two particles of momenta  $p_1$  and  $p_2$  and masses  $m_1$  and  $m_2$  scatter to particles of momenta  $p_3$  and  $p_4$  and masses  $m_3$  and  $m_4$ ; the Lorentz-invariant Mandelstam variables are defined by

$$\begin{aligned} s &= (p_1 + p_2)^2 = (p_3 + p_4)^2 \\ &= m_1^2 + 2E_1 E_2 - 2\mathbf{p}_1 \cdot \mathbf{p}_2 + m_2^2, \end{aligned} \quad (47.29)$$

$$\begin{aligned} t &= (p_1 - p_3)^2 = (p_2 - p_4)^2 \\ &= m_1^2 - 2E_1 E_3 + 2\mathbf{p}_1 \cdot \mathbf{p}_3 + m_3^2, \end{aligned} \quad (47.30)$$

$$\begin{aligned} u &= (p_1 - p_4)^2 = (p_2 - p_3)^2 \\ &= m_1^2 - 2E_1 E_4 + 2\mathbf{p}_1 \cdot \mathbf{p}_4 + m_4^2 , \end{aligned} \quad (47.31)$$

and they satisfy

$$s + t + u = m_1^2 + m_2^2 + m_3^2 + m_4^2 . \quad (47.32)$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s} \frac{1}{|\mathbf{p}_{1\text{cm}}|^2} |\mathcal{M}|^2 . \quad (47.33)$$

In the center-of-mass frame

$$\begin{aligned} t &= (E_{1\text{cm}} - E_{3\text{cm}})^2 - (p_{1\text{cm}} - p_{3\text{cm}})^2 \\ &= t_0 - 4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2) , \end{aligned} \quad (47.34)$$

where  $\theta_{\text{cm}}$  is the angle between particle 1 and 3. The limiting values  $t_0$  ( $\theta_{\text{cm}} = 0$ ) and  $t_1$  ( $\theta_{\text{cm}} = \pi$ ) for  $2 \rightarrow 2$  scattering are

$$t_0(t_1) = \left[ \frac{m_1^2 - m_3^2 - m_2^2 + m_4^2}{2\sqrt{s}} \right]^2 - (p_{1\text{cm}} \mp p_{3\text{cm}})^2 . \quad (47.35)$$

In the literature the notation  $t_{\min}$  ( $t_{\max}$ ) for  $t_0$  ( $t_1$ ) is sometimes used, which should be discouraged since  $t_0 > t_1$ . The center-of-mass energies and momenta of the incoming particles are

$$E_{1\text{cm}} = \frac{s + m_1^2 - m_2^2}{2\sqrt{s}} , \quad E_{2\text{cm}} = \frac{s + m_2^2 - m_1^2}{2\sqrt{s}} , \quad (47.36)$$

For  $E_{3\text{cm}}$  and  $E_{4\text{cm}}$ , change  $m_1$  to  $m_3$  and  $m_2$  to  $m_4$ . Then

$$p_{i\text{cm}} = \sqrt{E_{i\text{cm}}^2 - m_i^2} \text{ and } p_{1\text{cm}} = \frac{p_{1\text{lab}} m_2}{\sqrt{s}} . \quad (47.37)$$

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (47.2)–(47.4).]

**47.5.2. Inclusive reactions :** Choose some direction (usually the beam direction) for the  $z$ -axis; then the energy and momentum of a particle can be written as

$$E = m_T \cosh y , \quad p_x , \quad p_y , \quad p_z = m_T \sinh y , \quad (47.38)$$

where  $m_T$ , conventionally called the ‘transverse mass’, is given by

$$m_T^2 = m^2 + p_x^2 + p_y^2 . \quad (47.39)$$

and the rapidity  $y$  is defined by

$$y = \frac{1}{2} \ln \left( \frac{E + p_z}{E - p_z} \right)$$

$$= \ln \left( \frac{E + p_z}{m_T} \right) = \tanh^{-1} \left( \frac{p_z}{E} \right) . \quad (47.40)$$

Note that the definition of the transverse mass in Eq. (47.39) differs from that used by experimentalists at hadron colliders (see Sec. 47.6.1 below). Under a boost in the  $z$ -direction to a frame with velocity  $\beta$ ,  $y \rightarrow y - \tanh^{-1} \beta$ . Hence the shape of the rapidity distribution  $dN/dy$  is invariant, as are differences in rapidity. The invariant cross section may

also be rewritten

$$E \frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi dy p_T dp_T} \implies \frac{d^2\sigma}{\pi dy d(p_T^2)} . \quad (47.41)$$

The second form is obtained using the identity  $dy/dp_z = 1/E$ , and the third form represents the average over  $\phi$ .

Feynman's  $x$  variable is given by

$$x = \frac{p_z}{p_{z\max}} \approx \frac{E + p_z}{(E + p_z)_{\max}} \quad (p_T \ll |p_z|) . \quad (47.42)$$

In the c.m. frame,

$$x \approx \frac{2p_{z\text{cm}}}{\sqrt{s}} = \frac{2m_T \sinh y_{\text{cm}}}{\sqrt{s}} \quad (47.43)$$

and

$$= (y_{\text{cm}})_{\max} = \ln(\sqrt{s}/m) . \quad (47.44)$$

The invariant mass  $M$  of the two-particle system described in Sec. 47.4.2 can be written in terms of these variables as

$$M^2 = m_1^2 + m_2^2 + 2[E_T(1)E_T(2)\cosh\Delta y - \mathbf{p}_T(1) \cdot \mathbf{p}_T(2)] , \quad (47.45)$$

where

$$E_T(i) = \sqrt{|\mathbf{p}_T(i)|^2 + m_i^2} , \quad (47.46)$$

and  $\mathbf{p}_T(i)$  denotes the transverse momentum vector of particle  $i$ .

For  $p \gg m$ , the rapidity [Eq. (47.40)] may be expanded to obtain

$$\begin{aligned} y &= \frac{1}{2} \ln \frac{\cos^2(\theta/2) + m^2/4p^2 + \dots}{\sin^2(\theta/2) + m^2/4p^2 + \dots} \\ &\approx -\ln \tan(\theta/2) \equiv \eta \end{aligned} \quad (47.47)$$

where  $\cos\theta = p_z/p$ . The pseudorapidity  $\eta$  defined by the second line is approximately equal to the rapidity  $y$  for  $p \gg m$  and  $\theta \gg 1/\gamma$ , and in any case can be measured when the mass and momentum of the particle are unknown. From the definition one can obtain the identities

$$\sinh\eta = \cot\theta , \quad \cosh\eta = 1/\sin\theta , \quad \tanh\eta = \cos\theta . \quad (47.48)$$

## 47.6. Transverse variables

At hadron colliders, a significant and unknown proportion of the energy of the incoming hadrons in each event escapes down the beam-pipe. Consequently if invisible particles are created in the final state, their net momentum can only be constrained in the plane transverse to the beam direction. Defining the  $z$ -axis as the beam direction, this net momentum is equal to the missing transverse energy vector

$$\mathbf{E}_T^{\text{miss}} = -\sum_i \mathbf{p}_T(i) , \quad (47.49)$$

where the sum runs over the transverse momenta of all visible final state particles.

### 47.6.1. Single production with semi-invisible final state :

Consider a single heavy particle of mass  $M$  produced in association with visible particles which decays as in Fig. 47.1 to two particles, of which one (labeled particle 1) is invisible. The mass of the parent particle can be constrained with the quantity  $M_T$  defined by

$$\begin{aligned} M_T^2 &\equiv [E_T(1) + E_T(2)]^2 - [\mathbf{p}_T(1) + \mathbf{p}_T(2)]^2 \\ &= m_1^2 + m_2^2 + 2[E_T(1)E_T(2) - \mathbf{p}_T(1) \cdot \mathbf{p}_T(2)], \end{aligned} \quad (47.50)$$

where

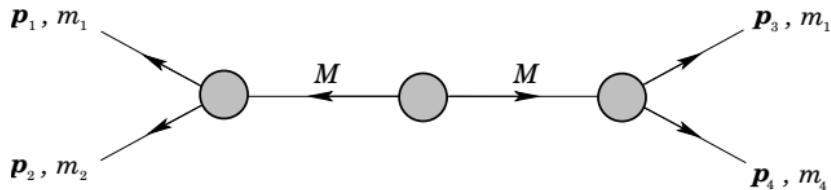

$$\mathbf{p}_T(1) = \mathbf{E}_T^{\text{miss}}. \quad (47.51)$$

This quantity is called the ‘transverse mass’ by hadron collider experimentalists but it should be noted that it is quite different from that used in the description of inclusive reactions [Eq. (47.39)]. The distribution of event  $M_T$  values possesses an end-point at  $M_T^{\max} = M$ . If  $m_1 = m_2 = 0$  then

$$M_T^2 = 2|\mathbf{p}_T(1)||\mathbf{p}_T(2)|(1 - \cos \phi_{12}), \quad (47.52)$$

where  $\phi_{ij}$  is defined as the angle between particles  $i$  and  $j$  in the transverse plane.

### 47.6.2. Pair production with semi-invisible final states :

**Figure 47.7:** Definitions of variables for pair production of semi-invisible final states. Particles 1 and 3 are invisible while particles 2 and 4 are visible.

Consider two identical heavy particles of mass  $M$  produced such that their combined center-of-mass is at rest in the transverse plane (Fig. 47.7). Each particle decays to a final state consisting of an invisible particle of fixed mass  $m_1$  together with an additional visible particle.  $M$  and  $m_1$  can be constrained with the variables  $M_{T2}$  and  $M_{CT}$  which are defined in Refs. [4] and [5].

## 49. Cross-section formulae for specific processes

Revised October 2009 by H. Baer (University of Oklahoma) and R.N. Cahn (LBNL).

### PART I: Standard Model Processes

Setting aside leptoproduction (for which, see Sec. 16 of this *Review*), the cross sections of primary interest are those with light incident particles,  $e^+e^-$ ,  $\gamma\gamma$ ,  $q\bar{q}$ ,  $gq$ ,  $gg$ , etc., where  $g$  and  $q$  represent gluons and light quarks. The produced particles include both light particles and heavy ones -  $t$ ,  $W$ ,  $Z$ , and the Higgs boson  $H$ . We provide the production cross sections calculated within the Standard Model for several such processes.

#### 49.1. Resonance Formation

Resonant cross sections are generally described by the Breit-Wigner formula (Sec. 18 of this *Review*).

$$\sigma(E) = \frac{2J+1}{(2S_1+1)(2S_2+1)} \frac{4\pi}{k^2} \left[ \frac{\Gamma^2/4}{(E-E_0)^2 + \Gamma^2/4} \right] B_{in} B_{out}, \quad (49.1)$$

where  $E$  is the c.m. energy,  $J$  is the spin of the resonance, and the number of polarization states of the two incident particles are  $2S_1+1$  and  $2S_2+1$ . The c.m. momentum in the initial state is  $k$ ,  $E_0$  is the c.m. energy at the resonance, and  $\Gamma$  is the full width at half maximum height of the resonance. The branching fraction for the resonance into the initial-state channel is  $B_{in}$  and into the final-state channel is  $B_{out}$ . For a narrow resonance, the factor in square brackets may be replaced by  $\pi\Gamma\delta(E-E_0)/2$ .

#### 49.2. Production of light particles

The production of point-like, spin-1/2 fermions in  $e^+e^-$  annihilation through a virtual photon,  $e^+e^- \rightarrow \gamma^* \rightarrow f\bar{f}$ , at c.m. energy squared  $s$  is

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta [1 + \cos^2 \theta + (1 - \beta^2) \sin^2 \theta] Q_f^2, \quad (49.2)$$

where  $\beta$  is  $v/c$  for the produced fermions in the c.m.,  $\theta$  is the c.m. scattering angle, and  $Q_f$  is the charge of the fermion. The factor  $N_c$  is 1 for charged leptons and 3 for quarks. In the ultrarelativistic limit,  $\beta \rightarrow 1$ ,

$$\sigma = N_c Q_f^2 \frac{4\pi\alpha^2}{3s} = N_c Q_f^2 \frac{86.8 \text{ nb}}{s(\text{GeV}^2)}. \quad (49.3)$$

The cross section for the annihilation of a  $q\bar{q}$  pair into a distinct pair  $q'\bar{q}'$  through a gluon is completely analogous up to color factors, with the replacement  $\alpha \rightarrow \alpha_s$ . Treating all quarks as massless, averaging over the colors of the initial quarks and defining  $t = -s \sin^2(\theta/2)$ ,  $u = -s \cos^2(\theta/2)$ , one finds

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q'\bar{q}') = \frac{\alpha_s^2}{9s} \frac{t^2 + u^2}{s^2}. \quad (49.4)$$

Crossing symmetry gives

$$\frac{d\sigma}{d\Omega}(qq' \rightarrow qq') = \frac{\alpha_s^2}{9s} \frac{s^2 + u^2}{t^2}. \quad (49.5)$$

If the quarks  $q$  and  $q'$  are identical, we have

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q\bar{q}) = \frac{\alpha_s^2}{9s} \left[ \frac{t^2 + u^2}{s^2} + \frac{s^2 + u^2}{t^2} - \frac{2u^2}{3st} \right], \quad (49.6)$$

and by crossing

$$\frac{d\sigma}{d\Omega}(qq \rightarrow qq) = \frac{\alpha_s^2}{9s} \left[ \frac{t^2 + s^2}{u^2} + \frac{s^2 + u^2}{t^2} - \frac{2s^2}{3ut} \right]. \quad (49.7)$$

Anihilation of  $e^+e^-$  into  $\gamma\gamma$  has the cross section

$$\frac{d\sigma}{d\Omega}(e^+e^- \rightarrow \gamma\gamma) = \frac{\alpha^2}{2s} \frac{u^2 + t^2}{tu}. \quad (49.8)$$

The related QCD process also has a triple-gluon coupling. The cross section is

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow gg) = \frac{8\alpha_s^2}{27s} (t^2 + u^2) \left( \frac{1}{tu} - \frac{9}{4s^2} \right). \quad (49.9)$$

The crossed reactions are

$$\frac{d\sigma}{d\Omega}(qg \rightarrow qg) = \frac{\alpha_s^2}{9s} (s^2 + u^2) \left( -\frac{1}{su} + \frac{9}{4t^2} \right), \quad (49.10)$$

$$\frac{d\sigma}{d\Omega}(gg \rightarrow q\bar{q}) = \frac{\alpha_s^2}{24s} (t^2 + u^2) \left( \frac{1}{tu} - \frac{9}{4s^2} \right), \quad (49.11)$$

$$\frac{d\sigma}{d\Omega}(gg \rightarrow gg) = \frac{9\alpha_s^2}{8s} \left( 3 - \frac{ut}{s^2} - \frac{su}{t^2} - \frac{st}{u^2} \right). \quad (49.12)$$

Lepton-quark scattering is analogous (neglecting  $Z$  exchange)

$$\frac{d\sigma}{d\Omega}(eq \rightarrow eq) = \frac{\alpha^2}{2s} e_q^2 \frac{s^2 + u^2}{t^2}, \quad (49.13)$$

$e_q$  is the quark charge. For  $\nu$ -scattering with the four-Fermi interaction

$$\frac{d\sigma}{d\Omega}(\nu d \rightarrow \ell^- u) = \frac{G_F^2 s}{4\pi^2}, \quad (49.14)$$

where the Cabibbo angle suppression is ignored. Similarly

$$\frac{d\sigma}{d\Omega}(\nu \bar{u} \rightarrow \ell^- \bar{d}) = \frac{G_F^2 s}{4\pi^2} \frac{(1 + \cos\theta)^2}{4}. \quad (49.15)$$

For deep inelastic scattering (presented in more detail in Section 19) we consider quarks of type  $i$  carrying a fraction  $x = Q^2/(2M\nu)$  of the nucleon's energy, where  $\nu = E - E'$  is the energy lost by the lepton in the nucleon rest frame. With  $y = \nu/E$  we have the correspondences

$$1 + \cos\theta \rightarrow 2(1 - y), \quad d\Omega_{cm} \rightarrow 4\pi f_i(x) dx dy, \quad (49.16)$$

where the latter incorporates the quark distribution,  $f_i(x)$ . We find

$$\begin{aligned} \frac{d\sigma}{dx dy}(eN \rightarrow eX) &= \frac{4\pi\alpha^2 xs}{Q^4} \frac{1}{2} \left[ 1 + (1 - y)^2 \right] \\ &\times \left[ \frac{4}{9}(u(x) + \bar{u}(x) + \dots) + \frac{1}{9}(d(x) + \bar{d}(x) + \dots) \right] \end{aligned} \quad (49.17)$$

where now  $s = 2ME$  is the cm energy squared for the electron-nucleon collision and we have suppressed contributions from higher mass quarks.

Similarly,

$$\frac{d\sigma}{dx dy}(\nu N \rightarrow \ell^- X) = \frac{G_F^2 xs}{\pi} [(d(x) + \dots) + (1 - y)^2 (\bar{u}(x) + \dots)], \quad (49.18)$$

$$\frac{d\sigma}{dx dy}(\bar{\nu} N \rightarrow \ell^+ X) = \frac{G_F^2 xs}{\pi} [(\bar{d}(x) + \dots) + (1 - y)^2 (u(x) + \dots)]. \quad (49.19)$$

Quasi-elastic neutrino scattering ( $\nu_\mu n \rightarrow \mu^- p$ ,  $\bar{\nu}_\mu p \rightarrow \mu^+ n$ ) is directly related to the crossed reaction, neutron decay.

### 49.3. Hadroproduction of heavy quarks

For hadroproduction of heavy quarks  $Q = c, b, t$ , it is important to include mass effects in the formulae. For  $q\bar{q} \rightarrow Q\bar{Q}$ , one has

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow Q\bar{Q}) = \frac{\alpha_s^2}{9s^3} \sqrt{1 - \frac{4m_Q^2}{s}} \left[ (m_Q^2 - t)^2 + (m_Q^2 - u)^2 + 2m_Q^2 s \right], \quad (49.20)$$

while for  $gg \rightarrow Q\bar{Q}$  one has

$$\begin{aligned} \frac{d\sigma}{d\Omega}(gg \rightarrow Q\bar{Q}) &= \frac{\alpha_s^2}{32s} \sqrt{1 - \frac{4m_Q^2}{s}} \left[ \frac{6}{s^2} (m_Q^2 - t)(m_Q^2 - u) \right. \\ &\quad \left. - \frac{m_Q^2(s - 4m_Q^2)}{3(m_Q^2 - t)(m_Q^2 - u)} + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + t)}{(m_Q^2 - t)^2} \right. \\ &\quad \left. + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + u)}{(m_Q^2 - u)^2} \right] \\ &- 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(u - t)}{s(m_Q^2 - t)} - 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(t - u)}{s(m_Q^2 - u)} \end{aligned} \quad (49.21)$$

### 49.4. Production of Weak Gauge Bosons

#### 49.4.1. $W$ and $Z$ resonant production :

Resonant production of a single  $W$  or  $Z$  is governed by the partial widths

$$\Gamma(W \rightarrow \ell_i \bar{\nu}_i) = \frac{\sqrt{2}G_F m_W^3}{12\pi} \quad (49.22)$$

$$\Gamma(W \rightarrow q_i \bar{q}_j) = 3 \frac{\sqrt{2}G_F |V_{ij}|^2 m_W^3}{12\pi} \quad (49.23)$$

$$\begin{aligned} \Gamma(Z \rightarrow f\bar{f}) &= N_c \frac{\sqrt{2}G_F m_Z^3}{6\pi} \\ &\times \left[ (T_3 - Q_f \sin^2 \theta_W)^2 + (Q_f \sin^2 \theta_W)^2 \right]. \end{aligned} \quad (49.24)$$

The weak mixing angle is  $\theta_W$ . The CKM matrix elements are  $V_{ij}$ .  $N_c$  is 3 for  $q\bar{q}$  and 1 for leptonic final states. These widths along with associated branching fractions may be applied to the resonance production formula of Sec. 49.1 to gain the total  $W$  or  $Z$  production cross section.

#### 49.4.2. Production of pairs of weak gauge bosons :

The cross section for  $f\bar{f} \rightarrow W^+W^-$  is given in term of the couplings of the left-handed and right-handed fermion  $f$ ,  $\ell = 2(T_3 - Qx_W)$ ,  $r = -2Qx_W$ , where  $T_3$  is the third component of weak isospin for the left-handed  $f$ ,  $Q$  is its electric charge (in units of the proton charge), and  $x_W = \sin^2 \theta_W$ :

$$\begin{aligned} \frac{d\sigma}{dt} &= \frac{2\pi\alpha^2}{N_c s^2} \left\{ \left[ \left( Q + \frac{\ell + r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 + \left( \frac{\ell - r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 \right] A(s, t, u) \right. \\ &\quad + \frac{1}{2x_W} \left( Q + \frac{\ell}{2x_W} \frac{s}{s - m_Z^2} \right) (\Theta(-Q)I(s, t, u) - \Theta(Q)I(s, u, t)) \\ &\quad \left. + \frac{1}{8x_W^2} (\Theta(-Q)E(s, t, u) + \Theta(Q)E(s, u, t)) \right\}, \end{aligned} \quad (49.26)$$

where  $\Theta(x)$  is 1 for  $x > 0$  and 0 for  $x < 0$ , and where

$$\begin{aligned} A(s, t, u) &= \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} - \frac{m_W^2}{s} + 3 \frac{m_W^4}{s^2} \right) + \frac{s}{m_W^2} - 4, \\ I(s, t, u) &= \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} - \frac{m_W^2}{2s} - \frac{m_W^4}{st} \right) + \frac{s}{m_W^2} - 2 + 2 \frac{m_W^2}{t}, \\ E(s, t, u) &= \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} + \frac{m_W^4}{t^2} \right) + \frac{s}{m_W^2}, \end{aligned} \quad (49.27)$$

and  $s, t, u$  are the usual Mandelstam variables with  $s = (p_f + p_{\bar{f}})^2, t = (p_f - p_{W-})^2, u = (p_f - p_{W+})^2$ . The factor  $N_c$  is 3 for quarks and 1 for leptons.

The analogous cross-section for  $q_i \bar{q}_j \rightarrow W^\pm Z^0$  is

$$\begin{aligned} \frac{d\sigma}{dt} &= \frac{\pi\alpha^2|V_{ij}|^2}{6s^2x_W^2} \left\{ \left( \frac{1}{s - m_W^2} \right)^2 \left[ \left( \frac{9 - 8x_W}{4} \right) (ut - m_W^2 m_Z^2) \right. \right. \\ &\quad \left. \left. + (8x_W - 6)s(m_W^2 + m_Z^2) \right] \right. \\ &\quad \left. + \left[ \frac{ut - m_W^2 m_Z^2 - s(m_W^2 + m_Z^2)}{s - m_W^2} \right] \left[ \frac{\ell_j}{t} - \frac{\ell_i}{u} \right] \right. \\ &\quad \left. + \frac{ut - m_W^2 m_Z^2}{4(1 - x_W)} \left[ \frac{\ell_j^2}{t^2} + \frac{\ell_i^2}{u^2} \right] + \frac{s(m_W^2 + m_Z^2)}{2(1 - x_W)} \frac{\ell_i \ell_j}{tu} \right\}, \end{aligned} \quad (49.28)$$

where  $\ell_i$  and  $\ell_j$  are the couplings of the left-handed  $q_i$  and  $q_j$  as defined above. The CKM matrix element between  $q_i$  and  $q_j$  is  $V_{ij}$ .

The cross section for  $q_i \bar{q}_i \rightarrow Z^0 Z^0$  is

$$\frac{d\sigma}{dt} = \frac{\pi\alpha^2}{96} \frac{\ell_i^4 + r_i^4}{x_W^2(1 - x_W^2)^2 s^2} \left[ \frac{t}{u} + \frac{u}{t} + \frac{4m_Z^2 s}{tu} - m_Z^4 \left( \frac{1}{t^2} + \frac{1}{u^2} \right) \right]. \quad (49.29)$$

## 49.5. Production of Higgs Bosons

### 49.5.1. Resonant Production :

The Higgs boson of the Standard Model can be produced resonantly in the collisions of quarks, leptons,  $W$  or  $Z$  bosons, gluons, or photons. The production cross section is thus controlled by the partial width of the Higgs boson into the entrance channel and its total width. The partial widths are given by the relations

$$\Gamma(H \rightarrow f\bar{f}) = \frac{G_F m_f^2 m_H N_c}{4\pi\sqrt{2}} \left( 1 - 4m_f^2/m_H^2 \right)^{3/2}, \quad (49.30)$$

$$\Gamma(H \rightarrow W^+ W^-) = \frac{G_F m_H^3 \beta_W}{32\pi\sqrt{2}} \left( 4 - 4a_W + 3a_W^2 \right), \quad (49.31)$$

$$\Gamma(H \rightarrow ZZ) = \frac{G_F m_H^3 \beta_Z}{64\pi\sqrt{2}} \left( 4 - 4a_Z + 3a_Z^2 \right). \quad (49.32)$$

where  $N_c$  is 3 for quarks and 1 for leptons and where  $a_W = 1 - \beta_W^2 = 4m_W^2/m_H^2$  and  $a_Z = 1 - \beta_Z^2 = 4m_Z^2/m_H^2$ . The decay to two gluons proceeds through quark loops, with the  $t$  quark dominating. Explicitly,

$$\Gamma(H \rightarrow gg) = \frac{\alpha_s^2 G_F m_H^3}{36\pi^3 \sqrt{2}} \left| \sum_q I(m_q^2/m_H^2) \right|^2, \quad (49.33)$$

where  $I(z)$  is complex for  $z < 1/4$ . For  $z < 2 \times 10^{-3}$ ,  $|I(z)|$  is small so the light quarks contribute negligibly. For  $m_H < 2m_t$ ,  $z > 1/4$  and

$$I(z) = 3 \left[ 2z + 2z(1-4z) \left( \sin^{-1} \frac{1}{2\sqrt{z}} \right)^2 \right], \quad (49.34)$$

which has the limit  $I(z) \rightarrow 1$  as  $z \rightarrow \infty$ .

#### 49.5.2. Higgs Boson Production in $W^*$ and $Z^*$ decay :

The Standard Model Higgs boson can be produced in the decay of a virtual  $W$  or  $Z$  (“Higgstrahlung”): In particular, if  $k$  is the c.m. momentum of the Higgs boson,

$$\sigma(q_i \bar{q}_j \rightarrow WH) = \frac{\pi \alpha^2 |V_{ij}|^2}{36 \sin^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_W^2}{(s - m_W^2)^2} \quad (49.35)$$

$$\sigma(f\bar{f} \rightarrow ZH) = \frac{2\pi \alpha^2 (\ell_f^2 + r_f^2)}{48 N_c \sin^4 \theta_W \cos^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_Z^2}{(s - m_Z^2)^2}. \quad (49.36)$$

where  $\ell$  and  $r$  are defined as above.

#### 49.5.3. $W$ and $Z$ Fusion :

Just as high-energy electrons can be regarded as sources of virtual photon beams, at very high energies they are sources of virtual  $W$  and  $Z$  beams. For Higgs boson production, it is the longitudinal components of the  $W$ s and  $Z$ s that are important. The distribution of longitudinal  $W$ s carrying a fraction  $y$  of the electron’s energy is

$$f(y) = \frac{g^2}{16\pi^2} \frac{1-y}{y}, \quad (49.37)$$

where  $g = e/\sin \theta_W$ . In the limit  $s \gg m_H \gg m_W$ , the rate  $\Gamma(H \rightarrow W_L W_L) = (g^2/64\pi)(m_H^3/m_W^2)$  and in the equivalent  $W$  approximation

$$\begin{aligned} \sigma(e^+ e^- \rightarrow \bar{\nu}_e \nu_e H) &= \frac{1}{16m_W^2} \left( \frac{\alpha}{\sin^2 \theta_W} \right)^3 \\ &\times \left[ \left( 1 + \frac{m_H^2}{s} \right) \log \frac{s}{m_H^2} - 2 + 2 \frac{m_H^2}{s} \right]. \end{aligned} \quad (49.38)$$

There are significant corrections to this relation when  $m_H$  is not large compared to  $m_W$ . For  $m_H = 150$  GeV, the estimate is too high by 51% for  $\sqrt{s} = 1000$  GeV, 32% too high at  $\sqrt{s} = 2000$  GeV, and 22% too high at  $\sqrt{s} = 4000$  GeV. Fusion of  $ZZ$  to make a Higgs boson can be treated similarly. Identical formulae apply for Higgs production in the collisions of quarks whose charges permit the emission of a  $W^+$  and a  $W^-$ , except that QCD corrections and CKM matrix elements are required. Even in the absence of QCD corrections, the fine-structure constant ought to be evaluated at the scale of the collision, say  $m_W$ . All quarks contribute to the  $ZZ$  fusion process.

## 50. Neutrino Cross Section Measurements

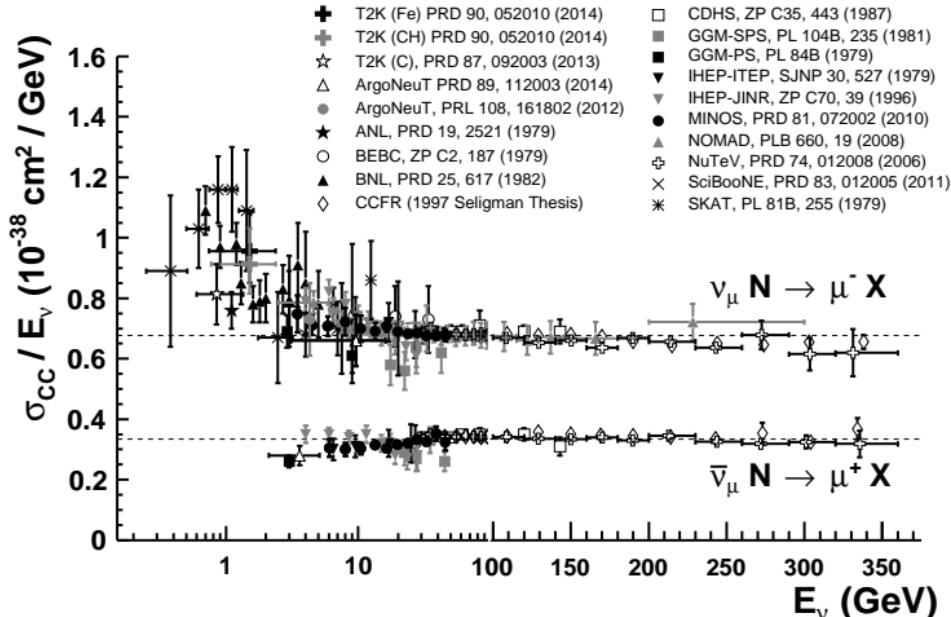

Revised August 2017 by G.P. Zeller (Fermilab)

Highlights from full review.

Neutrino cross sections are an essential ingredient in all neutrino experiments. This work summarizes accelerator-based neutrino cross section measurements performed in the  $\sim 0.1 - 300$  GeV range with an emphasis on inclusive, quasi-elastic, and pion production processes, areas where we have the most experimental input at present.

**Table 50.1:** List of modern accelerator-based neutrino experiments studying neutrino scattering.

Experiment	beam	$\langle E_{\nu, \bar{\nu}} \rangle$ GeV	target(s)	run period
ArgoNeuT	$\nu, \bar{\nu}$	4.3, 3.6	Ar	2009 – 2010
ICARUS	$\nu$	20.0	Ar	2010 – 2012
K2K	$\nu$	1.3	CH, H <sub>2</sub> O	2003 – 2004
MicroBooNE	$\nu$	0.8	Ar	2015 –
MINERvA	$\nu, \bar{\nu}$	3.5 (LE), 5.5 (ME)	He, C, CH, H <sub>2</sub> O, Fe, Pb	2009 –
MiniBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH <sub>2</sub>	2002 – 2012
MINOS	$\nu, \bar{\nu}$	3.5, 6.1	Fe	2004 – 2016
NOMAD	$\nu, \bar{\nu}$	23.4, 19.7	C-based	1995 – 1998
NOvA	$\nu, \bar{\nu}$	2.0, 2.0	CH <sub>2</sub>	2010 –
SciBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH	2007 – 2008
T2K	$\nu, \bar{\nu}$	0.6, 0.6	CH, H <sub>2</sub> O, Fe	2010 –

**Figure 50.1:** Measurements of per nucleon  $\nu_\mu$  and  $\bar{\nu}_\mu$  CC inclusive scattering cross sections divided by neutrino energy as a function of neutrino energy. Note the transition between logarithmic and linear scales occurring at 100 GeV.

## 6. Atomic and Nuclear Properties of Materials

**Table 6.1.** Abridged from pdg.lbl.gov/AtomicNuclearProperties by D. E. Groom (2017). See web pages for more detail about entries in this table and for several hundred others. Quantities in parentheses are for gases at 20°C and 1 atm. Boiling points are at 1 atm. Refractive indices  $n$  are evaluated at the sodium D line blend (589.2 nm); values  $\gg 1$  in brackets are for  $(n - 1) \times 10^6$  (gases) at 0°C and 1 atm.
