$\rho(1700)$

$I^G(J^{PC}) = 1^+(1^{--})$

NOTE ON THE $\rho(1450)$ AND THE $\rho(1700)$

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ-like resonances. ERKAL 86 had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. DONNACHIE 87, with a full analysis of data in the annihilation reactions $e^+e^- \to \pi^+\pi^-$, $2\pi^+2\pi^-$, and $\pi^+\pi^-\pi^0\pi^0$, and in the photoproduction reactions $\gamma p \to \pi^+\pi^- p$, $2\pi^+2\pi^- p$, and $\pi^+\pi^-\pi^0\pi^0 p$, had also argued that to obtain a consistent picture two resonances, whose masses and widths could be fixed reasonably well, were necessary. This picture was supported by the analysis of DONNACHIE 87B of $J^P = 1^-$ $\eta\rho^0$ mass spectra obtained in photoproduction and in e^+e^- annihilations; the analysis showed the need for a contribution from a ρ meson with a mass of about 1470 MeV, but could say little about a higher-mass resonance (actually the data could be explained without it). Confirmation of the decay $\rho(1450) \to \omega\pi$, and a tight constraint on the mass due to strong interference with the $\rho(770)$ tail, was found by DONNACHIE 91 in an analysis of $e^+e^- \to \omega\pi$.

The analysis of DONNACHIE 87 was extended by CLEGG 88 to include new data on 4π systems produced in e^+e^- annihilation and in τ decay (4π τ decays and 4π annihilation reactions can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ-like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \to 4\pi$ were obtained, the quality of the data used by CLEGG 88 prevented any conclusion on $\rho(1700) \to 4\pi$ decay.

An analysis by CLEGG 90 of 6π mass spectra from e^+e^- annihilation and from diffractive photoproduction provides evidence for two ρ mesons at about 2.1 and 1.8 GeV that decay strongly into 6π states. While the former is a candidate for a new resonance, the latter could be a manifestation of the $\rho(1700)$, distorted by threshold effects.

Independent evidence for two 1^- states is provided by KILLIAN 80 in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)^2, and by FUKUI 88 in a high-statistics sample of the $\eta\pi\pi$ system in $\pi^- p$ charge exchange.

This scenario with two overlapping resonances is supported by other data. BISELLO 89 measured the pion form factor in the interval 1.35–2.4 GeV with significant statistics (280 $e^+e^- \to \pi^+\pi^-$ events with very low background); a deep minimum is observed around 1.6 GeV, and the best fit to the form factor is obtained with the hypothesis of ρ-like resonances at 1420 and 1770 MeV with widths of about 250 MeV. ANTONELLI 88 found that the $e^+e^- \to \eta\pi^+\pi^-$ cross section (using three different η decay modes) is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of DONNACHIE 87 and BISELLO 89.

These results (although ANTONELLI 88 is statistically less significant than BISELLO 89) have also resolved the disagreement between DONNACHIE 87 and FUKUI 88 on the $\rho(1450)$ width in favor of the DONNACHIE 87 value. From this point of view, the two experiments can be considered as solid confirmation of the $\rho(1450)$. For the possibility that its $\phi\pi$ mode actually contains two independent vector states, see LANDSBERG 92.

Several observations on the $\omega\pi$ system in the 1200-MeV region (FRENKIEL 72, COSME 76, BARBER 80C, ASTON 80C, ATKINSON 84C, BRAU 88, AMSLER 93B) may be interpreted in terms of either $J^P = 1^-$ $\rho(770) \to \pi\omega$ production (LAYSSAC 71) or $J^P = 1^+$ $b_1(1235)$ production (BRAU 88, AMSLER 93B). We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis (ASTON 91B) showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

$X(1700)$

$I^G(J^{PC}) = \text{even}^+(?^?+)$

OMITTED FROM SUMMARY TABLE

Enhancement seen in the $\eta\pi\pi$ system produced in the radiative decay of the $J/\psi(1S)$. May contain significant substructure. Relation to other enhancements seen in radiative $J/\psi(1S)$ decay unclear (see HITLIN 83). Enhancement seen in the $J = 2$, $\rho\pi\pi$ wave of the $\pi^+\pi^-\pi^+\pi^-$ system produced in pomeron-pomeron collisions. Tentatively called $X(1700)$ by us. Needs confirmation.

$f_J(1710)$ was $\theta(1690)$

$I^G(J^{PC}) = 0^+(\text{even}^{++})$

NOTE ON THE $f_J(1710)$

The $f_J(1710)$ is seen in the "gluon rich" radiative decay $J/\psi(1S) \to \gamma f_J(1710)$; therefore $C = +$. It decays into 2η and $K^0_S K^0_S$, which implies $I^G J^{PC} = 0^+(\text{even})^{++}$. In an amplitude analysis of the $K\overline{K}$ and $\pi^+\pi^-$ systems produced in $J/\psi(1S)$ radiative decay, CHEN 91 finds a large spin-0 component for this particle, but WA 76 favors spin 2 in central production. The spin is thus uncertain. This resonance is also observed in $K\overline{K}$ systems recoiling against a ϕ or an ω in hadronic $J/\psi(1S)$ decay [however, according to FALVARD 88, $J/\psi(1S) \to \omega f_J(1710)$ is rather controversial]. The $f_J(1710)$ is not seen in $J/\psi(1S) \to \gamma\rho^0\rho^0$ (BISELLO 89B), in agreement with the indication (BALTRUSAITIS 85G) that the $\rho\rho$ enhancement in this region has $J^P = 0^-$, and hence is unrelated to the $f_J(1710)$.

Clear evidence is seen in hadroproduction (ARMSTRONG 89D, 300-GeV/c pp central production of $K\overline{K}$), both in K^+K^- and $K^0_S K^0_S$. Mass and width determinations are complicated because the spectra are dominated by overlap with the $f'_2(1525)$. The apparent large disagreement between the widths found by ARMSTRONG 89D in the two channels ($\approx$ 180 MeV in K^+K^- and $\approx$ 100 MeV in $K^0_S K^0_S$) can be explained by the arbitrariness of the polynomial-exponential background shape, which leads to a large systematic error for the width. ARMSTRONG 93C also sees in $\eta\eta$ a broad peak at 1747 MeV, which may be the $f_J(1710)$. This resonance is not observed in the exclusive hypercharge-exchange reaction $K^-p \to K^0_S K^0_S \Lambda$ (ASTON 88D).

A partial-wave analysis of the $K^0_S K^0_S$ system (BOLONKIN 88) finds a D_0 wave ($J^{PC} = 2^{++}$) behavior near 1700 MeV, but the width ($\approx$ 30 MeV) is much narrower than that observed in $J/\psi(1S)$ decays and in hadroproduction.

Note that in our 1992 edition, this particle was named the $f_2(1710)$; see also our "Note on Non-$q\bar{q}$ Mesons."

[1] Not seen by GRAF 91.
[2] Not seen by CHIBA 88, ANGELOPOULOS 86, ADIELS 86.
[3] They looked for radiative transitions to bound $p\overline{p}$ states, mono-energetic γ rays detected.
[4] Observed widths consistent with experimental resolution.
[5] Not seen by ADIELS 86.
[6] From analysis of difference of π^- and π^+ spectra.
[7] Not seen by CHIBA 88, ANGELOPOULOS 86.
[8] Produced backwards.
[9] $I(J^P) = 1(1^-)$ from a mass dependent partial-wave analysis taking solution A.
[10] From reanalysis of data from JASTRZEMBSKI 81.
[11] Not seen by BUSENITZ 89.
[12] From energy dependence of 5π cross section. $I^G = 1^-$ from observation of $\omega\rho$ decay. $P = +$ and $J > 1$. $a_2(1320)\pi\pi$ also seen.
[13] $I = 0$ favored, $J = 0$ or 1, seen in total $\overline{p}p$ total cross section. Primarily from annihilation reactions. Not seen in $\overline{p}d$ total and annihilation cross sections.
[14] Narrow bump seen in total $\overline{p}p$, $\overline{p}d$ cross sections. Isospin uncertain. Not seen in $\overline{p}p$ charge exchange by ALSTON-GARNJOST 75, CHALOUPKA 76. Integrated cross section three times larger than BRUCKNER 77.
[15] Narrow bump seen in total $\overline{p}p$, $\overline{p}d$ cross sections. Isospin uncertain. Not seen in $\overline{p}p$ charge exchange by ALSTON-GARNJOST 75, CHALOUPKA 76. Integrated cross section three times larger than BRUCKNER 77. Not seen by CLOUGH 84.
[16] From energy dependence of far backward elastic scattering. Some indication of additional structure.

[17] From energy dependence of far backward elastic scattering. Some indication of additional structure.
[18] Not seen by ALBERI 79 with comparable statistics.
[19] Not seen by ALBERI 79 with comparable statistics.
[20] Seen as a bump in the $\bar{p}p \to K^0_S K^0_L$ cross section with $J^{PC} = 1^{--}$.
[21] Isospin 1 favored.
[22] Not seen by BIONTA 80, CARROLL 80, HAMILTON 80, BANKS 81, CHUNG 81, BARNETT 83.
[23] Neutron spectator. See also $np\bar{p}\pi^-(p)$ channel following.
[24] Proton spectator. See also $p\bar{p}n(n)$ channel above.
[25] $I(J^P) = 1(3^-)$ from a mass dependent partial-wave analysis taking solution A.
[26] $I(J^P) = 1(3^-)$ from amplitude analysis assuming one-pion exchange.
[27] Seen in final state $\omega\pi^+\pi^-$.
[28] $I(J^P) = 0(2^+)$ from amplitude analysis assuming one-pion exchange.
[29] ALLES-BORELLI 67B see neutral mode only $\pi^+\pi^-\pi^0$.
[30] $I(J^P) = 0(4^+)$ from a mass dependent partial-wave analysis taking solution A.
[31] $I(J^P) = 0(4^+)$ from amplitude analysis assuming one-pion exchange.
[32] $I(J^P) = 1(5^-)$ from amplitude analysis assuming one-pion exchange.
[33] $I(J^P) = 1(5^-)$ from amplitude analysis of $\bar{p}p \to \pi\pi$.
[34] I=0,1 $J^P = 5^-$ from Barrelet-zero analysis.
[35] Decays to $\overline{N}N$ and $\overline{N}N\pi$. Not seen by BARNETT 83.
[36] Decays to $4\pi^+4\pi^-$.

$X(1900–3600)$

OMITTED FROM SUMMARY TABLE

NOTE ON THE $X(1900–3600)$ REGION

The high-mass region is covered nearly continuously with evidence for peaks of various widths having various decay modes. As a satisfactory grouping into particles is not yet possible, we list all the $Y = 0$ bumps coupled neither to $\overline{N}N$ nor to e^+e^-, and having $M > 1900$ MeV, together, ordered by increasing mass.

The narrow peaks observed in a missing-mass-spectrometer experiment at 1929, 2195, and 2382 MeV, called respectively S, T, and U by the authors (CHIKOVANI 66, FOCACCI 66), were not seen by ANTIPOV 72, who performed a similar experiment at 25 and 40 GeV/c.

STRANGE MESONS
($S = \pm 1$, $C = B = 0$)

$K^+ = u\bar{s}$, $K^0 = d\bar{s}$, $\overline{K}^0 = \bar{d}s$, $K^- = \bar{u}s$, similarly for K^*'s

$K^{\pm}$ $I(J^P) = \frac{1}{2}(0^-)$

NOTE ON THE CHARGED KAON MASS

The average of the six charged kaon mass measurements which we use in the Full Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV (S = 2.4)}, \quad (1)$$

where the error has been increased by the scale factor S. The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV},$$
$$\chi^2 = 22.9 \text{ for 5 D.F., Prob. } = 0.04\%, \quad (2)$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$m_{K^\pm}$ =493.696 ± 0.007 MeV DENISOV 91

$m_{K^\pm}$ =493.636 ± 0.011 MeV (S = 1.5) GALL 88

Average =493.679 ± 0.006 MeV

$$\chi^2 = 21.2 \text{ for 1 D.F., Prob. } = 0.0004\%, \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2.

The GALL 88 measurement was made using four different kaonic atom transitions, K^- Pb (9 → 8), K^- Pb (11 → 10), K^- W (9 → 8), and K^- W (11 → 10). The $m_{K^\pm}$ values they obtain from each of these transitions is shown in the Full Listings and in Fig. 1. Their K^- Pb (9 → 8) $m_{K^\pm}$is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007,$$
$$\chi^2 = 7.0 \text{ for 3 D.F., Prob. } = 7.2\%. \quad (4)$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by S=1.5 to obtain their published error ±0.011 shown in Eq. (3) above and used in the Full Listings average.

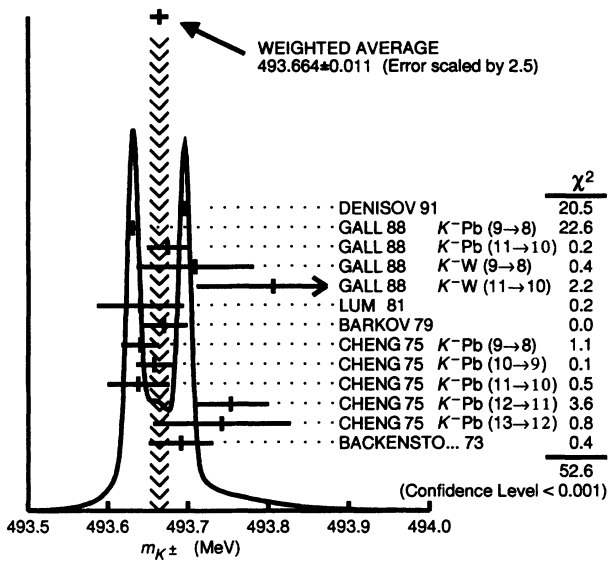

Figure 1: Ideogram of $m_{K^\pm}$ mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 K^- Pb (9 → 8) measurement yield two well-separated peaks. One might suspect the GALL 88 K^- Pb (9 → 8) measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the K^- Pb (9 → 8) transition, we have separated the CHENG 75 data, which also used K^- Pb, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 K^- Pb (9 → 8) values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the K^- Pb (9 → 8) transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the K^- Pb (9 → 8) transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 K^- Pb (9 → 8) [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the K^- Pb (9 → 8) transition produces the most consistent set of data, but that excluding only the GALL 88 K^- Pb (9 → 8) transition or DENISOV 91 also produces acceptable probabilities.

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ-ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 $m_{K^\pm}$ values could be raised by about 15 keV and 22 keV, respectively. With these

Table 1: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data.

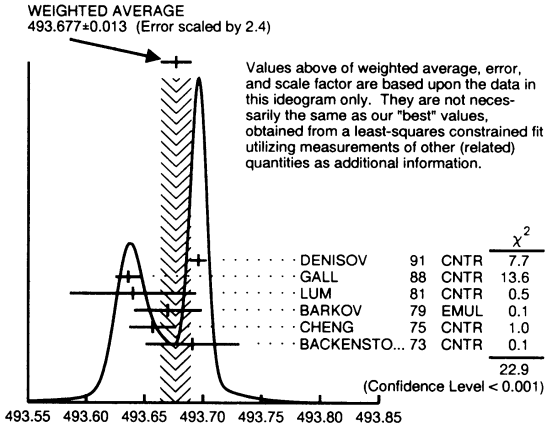
$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no K^- Pb(9→8)
493.687 ± 0.006	14.6	11	20	no GALL 88 K^- Pb(9→8)
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 → 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 → 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9→8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9→8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nucleii (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C. The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C, which is good agreement with the calculated energy.



While we suspect that the GALL 88 K^- Pb (9 → 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

[1] Error increased from 0.0059 based on the error analysis in IVANOV 92.
[2] This value is the authors' combination of all of the separate transitions listed for this paper.
[3] The CHENG 75 values for separate transitions were calculated from their Table 7 transition energies. The first error includes a 20% systematic error in the noncircular contaminant shift. The second error is due to a ±5 eV uncertainty in the theoretical transition energies.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[c] Direct-emission branching fraction.

[d] Structure-dependent part.

[e] Derived from an analysis of neutrino-oscillation experiments.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, 2 decay rate, and 20 branching ratios uses 60 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 74.9$ for 53 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[25] LUCAS 73B gives $N(K_{\mu 3}) = 554 \pm 7.6\%$, $N(K_{e3}) = 786 \pm 3.1\%$. We divide.
[26] CHIANG 72 $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma(\pi^0e^+\nu_e)$ is statistically independent of CHIANG 72 $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma_{total}$ and $\Gamma(\pi^0e^+\nu_e)/\Gamma_{total}$.
[27] From CALLAHAN 66B we use only the $K_{\mu 3}/K_{e3}$ ratio and do not include in the fit the ratios $K_{\mu 3}/(\pi\pi^+\pi^0)$ and $K_{e3}/(\pi\pi^+\pi^0)$, since they show large disagreements with the rest of the data.
[28] HEINTZE 77 value from fit to λ_0. Assumes μ-e universality.
[29] BRAUN 75 value is from form factor fit. Assumes μ-e universality.
[30] HAIDT 71 is a reanalysis of EICHTEN 68. Only individual ratios included in fit (see $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma(\pi^+\pi^+\pi^-)$ and $\Gamma(\pi^0e^+\nu_e)/\Gamma(\pi^+\pi^+\pi^-)$).

$[\Gamma(\pi^+\pi^0) + \Gamma(\pi^0\mu^+\nu_\mu)]/\Gamma_{total}$ $(\Gamma_3+\Gamma_6)/\Gamma$

We combine these two modes for experiments measuring them in xenon bubble chamber because of difficulties of separating them there.

0.53±0.22		[47] ROMANO	71	HLBC	+	$E(\gamma) > 30$ MeV
1.2 ±0.8		BELLOTTI	67	HLBC	+	$E(\gamma) > 30$ MeV

[45] BARMIN 91 quotes branching ratio $\Gamma(K \to e\pi^0\nu\gamma)/\Gamma_{all}$. The measured normalization is $[\Gamma(K \to e\pi^0\nu) + \Gamma(K \to \pi^+\pi^+\pi^-)]$. For comparison with other experiments we used $\Gamma(K \to e\pi^0\nu)/\Gamma_{all} = 0.0482$ to calculate the values quoted here.
[46] $\cos\theta(e\gamma)$ between 0.6 and 0.9.
[47] Both ROMANO 71 values are for $\cos\theta(e\gamma)$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest $E(\gamma)$ cut for Summary Table value. See ROMANO 71 for E_γ dependence.
[48] First LJUNG 73 value is for $\cos\theta(e\gamma) < 0.9$, second value is for $\cos\theta(e\gamma)$ between 0.6 and 0.9 for comparison with ROMANO 71.

NOTE ON DALITZ PLOT PARAMETERS FOR $K \to 3\pi$ DECAYS

The Dalitz plot distribution for $K^{\pm} \to \pi^{\pm}\pi^{\pm}\pi^{\mp}$, $K^{\pm} \to \pi^0\pi^0\pi^{\pm}$, and $K_L^0 \to \pi^+\pi^-\pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$|M|^2 \propto 1 + g\frac{(s_3 - s_0)}{am_{\pi+}^2} + h\left[\frac{s_3 - s_0}{m_{\pi+}^2}\right]^2 + j\frac{(s_2 - s_1)}{m_{\pi+}^2} + ak\left[\frac{s_2 - s_1}{m_{\pi+}^2}\right]^2 + \cdots , \quad (1)$$

where $m_{\pi+}^2$ has been introduced to make the coefficients g, h, j, and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i \ , \ i = 1, 2, 3,$$

$$s_0 = \frac{1}{3}\sum_i s_i = \frac{1}{3}(m_K^2 + m_1^2 + m_2^2 + m_3^2)$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g, h, and k must be the same for $K^+ \to \pi^+\pi^+\pi^-$ as for $K^- \to \pi^-\pi^-\pi^+$.

Since different experiments use different forms for $|M|^2$, in order to compare the experiments we have converted to g, h, j, and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y, a_t, a_u, or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

NOTE ON $K^{\pm}_{\ell 3}$ AND $K^{0}_{\ell 3}$ FORM FACTORS

Assuming that only the vector current contributes to $K \to \pi\ell\nu$ decays, we write the matrix element as

$$M \propto f_+(t)\left[(P_K + P_\pi)_\mu \bar{\ell}\gamma_\mu(1+\gamma_5)\nu\right] + f_-(t)\left[m_\ell \bar{\ell}(1+\gamma_5)\nu\right] , \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments measure f_+ and f_-, while K_{e3} experiments are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

(a) $K_{\mu 3}$ experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t, *i.e.*,

$$f_\pm(t) = f_\pm(0)\left[1 + \lambda_\pm(t/m_\pi^2)\right] \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (*i.e.*, $\lambda_- = 0$). There are two equivalent parametrizations commonly used in these analyses:

(1) $\lambda_+, \xi(0)$ parametrization. Analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t) .$$

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$). These parameters can be determined by three different methods:

Method A. By studying the Dalitz plot or the pion spectrum of $K_{\mu 3}$ decay. The Dalitz plot density is (see, *e.g.*, Chounet *et al.* [1]):

$$\rho(E_\pi, E_\mu) \propto f_+^2(t)\left[A + B\xi(t) + C\xi(t)^2\right] ,$$

where

$$A = m_K\left(2E_\mu E_\nu - m_K E'_\pi\right) + m_\mu^2\left(\frac{1}{4}E'_\pi - E_\nu\right) ,$$

$$B = m_\mu^2\left(E_\nu - \frac{1}{2}E'_\pi\right) ,$$

$$C = \frac{1}{4}m_\mu^2 E'_\pi ,$$

$$E'_\pi = E_\pi^{\max} - E_\pi = \left(m_K^2 + m_\pi^2 - m_\mu^2\right)/2m_K - E_\pi .$$

Here E_π, E_μ, and E_ν are, respectively, the pion, muon, and neutrino energies in the kaon center of mass. The density ρ is fit to the data to determine the values of $\lambda_+, \xi(0)$, and their correlation.

Method B. By measuring the $K_{\mu 3}/K_{e3}$ branching ratio and comparing it with the theoretical ratio (see, *e.g.*, Fearing *et al.* [2]) as given in terms of λ_+ and $\xi(0)$, assuming μ-e universality:

$$\Gamma(K^\pm_{\mu 3})/\Gamma(K^\pm_{e3}) = 0.6457 + 1.4115\lambda_+ + 0.1264\xi(0) + 0.0192\xi(0)^2 + 0.0080\lambda_+\xi(0) ,$$

$$\Gamma(K^0_{\mu 3})/\Gamma(K^0_{e3}) = 0.6452 + 1.3162\lambda_+ + 0.1264\xi(0) + 0.0186\xi(0)^2 + 0.0064\lambda_+\xi(0) .$$

This cannot determine λ_+ and $\xi(0)$ simultaneously but simply fixes a relationship between them.

Method C. By measuring the muon polarization in $K_{\mu 3}$ decay. In the rest frame of the K, the μ is expected to be polarized in the direction $\mathbf{A}$ with $\mathbf{P} = \mathbf{A}/|\mathbf{A}|$, where $\mathbf{A}$ is given (Cabibbo and Maksymowicz [3]) by

$$\mathbf{A} = a_1(\xi)\mathbf{p}_\mu - a_2(\xi)\left[\frac{\mathbf{p}_\mu}{m_\mu}\left(m_K - E_\pi + \frac{\mathbf{p}_\pi\cdot\mathbf{p}_\mu}{|\mathbf{p}_\mu|^2}(E_\mu - m_\mu)\right) + \mathbf{p}_\pi\right] + m_K \mathrm{Im}\xi(t)(\mathbf{p}_\pi \times \mathbf{p}_\mu) .$$

If time-reversal invariance holds, ξ is real, and thus there is no polarization perpendicular to the K-decay plane. Polarization experiments measure the weighted average of $\xi(t)$ over the t range of the experiment, where the weighting accounts for the variation with t of the sensitivity to $\xi(t)$.

(2) λ_+, λ_0 parametrization. Most of the more recent $K_{\mu 3}$ analyses have parameterized in terms of the form factors f_+ and f_0 which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + \left[t/(m_K^2 - m_\pi^2)\right] f_-(t) .$$

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t:

$$f_0(t) = f_0(0)\left[1 + \lambda_0(t/m_\pi^2)\right] .$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

The experimental results for $\xi(0)$ and its correlation with λ_+ are listed in the $K^\pm$ and K^0_L sections of the Full Listings in section ξ_A, ξ_B, or ξ_C depending on whether method A, B, or C discussed above was used. The corresponding values of λ_+ are also listed.

Because recent experiments tend to use the (λ_+, λ_0) parametrization, we include a subsection for λ_0 results. Wherever possible we have converted $\xi(0)$ results into λ_0 results and vice versa.

See key on page 1343

See the 1982 version of this note [4] for additional discussion of the $K^0_{\mu 3}$ parameters, correlations, and conversion between parametrizations, and also for a comparison of the experimental results.

(b) K_{e3} experiments. Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ is usually assumed to be linear in t, and the linear coefficient λ_+ of Eq. (2) is determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (2), would contain

$$+2m_K f_S \bar{\ell}(1+\gamma_5)\nu$$

$$+(2f_T/m_K)(P_K)_\lambda(P_\pi)_\mu \bar{\ell}\sigma_{\lambda\mu}(1+\gamma_5)\nu\ ,$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

$K^{\pm}_{\ell 3}$ FORM FACTORS

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.
f_S and f_T refer to the scalar and tensor term.
$f_0 = f_+ + f_- t/(m_K^2 - m_\pi^2)$.
λ_+, λ_-, and λ_0 are the linear expansion coefficients of f_+, f_-, and f_0.
λ_+ refers to the $K^{\pm}_{\mu 3}$ value except in the $K^{\pm}_{e3}$ sections.
$d\xi(0)/d\lambda_+$ is the correlation between $\xi(0)$ and λ_+ in $K^{\pm}_{\mu 3}$.
$d\lambda_0/d\lambda_+$ is the correlation between λ_0 and λ_+ in $K^{\pm}_{\mu 3}$.
t = momentum transfer to the π in units of m_π^2.
DP = Dalitz plot analysis.
PI = π spectrum analysis.
MU = μ spectrum analysis.
POL= μ polarization analysis.
BR = $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ branching ratio analysis.
E = positron or electron spectrum analysis.
RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K^{\pm}_{e3}$ DECAY)

For radiative correction of $K^{\pm}_{e3}$ Dalitz plot, see GINSBERG 67 and BECHERRAWY 70.

0.025 ±0.007		[75] BRAUN	74	HLBC	+	$K_{\mu 3}/K_{e3}$ vs. t

[72] AKIMENKO 91 state that radiative corrections would raise λ_+ by 0.0013.

[73] BOLOTOV 88 state radiative corrections of GINSBERG 67 would raise λ_+ by 0.002.

[74] BRAUN 73B states that radiative corrections of GINSBERG 67 would lower λ_+^e by 0.002 but that radiative corrections of BECHERRAWY 70 disagrees and would raise λ_+^e by 0.005.

[75] BRAUN 74 is a combined $K_{\mu 3}$-K_{e3} result. It is not independent of BRAUN 73C ($K_{\mu 3}$) and BRAUN 73B (K_{e3}) form factor results.

$\xi_A = f_-/f_+$ (determined from $K^{\pm}_{\mu 3}$ spectra)

The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

+1.8 ±0.6		76	BROWN	62B	XEBC	+	DP+BR, λ_+=0

[76] ARNOLD 74 figure 4 was used to obtain ξ_A and $d\xi(0)/d\lambda_+$.

[77] MERLAN 74 figure 5 was used to obtain $d\xi(0)/d\lambda_+$.

[78] BRAUN 73C gives $\xi(t) = -0.34 \pm 0.20$, $d\xi(t)/d\lambda_+ = -14$ for $\lambda_+ = 0.027$, $t = 6.6$. We calculate above $\xi(0)$ and $d\xi(0)/d\lambda_+$ for their $\lambda_+ = 0.025 \pm 0.017$.

[79] ANKENBRANDT 72 figure 3 was used to obtain $d\xi(0)/d\lambda_+$.

[80] CHIANG 72 figure 10 was used to obtain $d\xi(0)/d\lambda_+$. Fit had $\lambda_- = \lambda_+$ but would not change for $\lambda_- = 0$. L.Pondrom, (private communication 74).

[81] HAIDT 71 table 8 (Dalitz plot analysis) gives $d\xi(0)/d\lambda_+ = (-1.1+0.5)/(0.050-0.029) = -29$, error raised from 0.50 to agree with $d\xi(0) = 0.20$ for fixed λ_+.

[82] KIJEWSKI 69 figure 17 was used to obtain $d\xi(0)/d\lambda_+$ and errors.

[83] CALLAHAN 66 table 1 (π analysis) gives $d\xi(0)/d\lambda_+ = (0.72–0.05)/(0–0.04) = -17$, error raised from 0.80 to agree with $d\xi(0) = 0.37$ for fixed λ_+. t unknown.

[84] JENSEN 64 gives $\lambda_+^\mu = \lambda_+^e = -0.020 \pm 0.027$. $d\xi(0)/d\lambda_+$ unknown. Includes SHAKLEE 64 $\xi_B(K_{\mu3}/K_{e3})$.

$\xi_B = f_-/f_+$ (determined from $K^{\pm}_{\mu3}/K^{\pm}_{e3}$)

The $K^{\pm}_{\mu3}/K^{\pm}_{e3}$ branching ratio fixes a relationship between $\xi(0)$ and λ_+. We quote the author's $\xi(0)$ and associated λ_+ but do not average because the λ_+ values differ. The fit result and scale factor given below are not obtained from these ξ_B values. Instead they are obtained directly from the fitted $K^{\pm}_{\mu3}/K^{\pm}_{e3}$ ratio $\Gamma(\pi^0\mu^+\nu_\mu)/\Gamma(\pi^0 e^+\nu_e)$, with the exception of HEINTZE 77. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

[85] Calculated by us from λ_0 and λ_+ given below.

[86] EICHTEN 68 has $\lambda_+ = 0.023 \pm 0.008$, $t = 4$, independent of λ_-. Replaced by HAIDT 71.

[87] BOTTERILL 70 is re-evaluation of BOTTERILL 68B with different λ_+.

$\xi_C = f_-/f_+$ (determined from μ polarization in $K^{\pm}_{\mu3}$)

The μ polarization is a measure of $\xi(t)$. No assumptions on λ_{+-} necessary, t (weighted by sensitivity to $\xi(t)$) should be specified. In λ_+, $\xi(0)$ parametrization this is $\xi(0)$ for λ_+=0. $d\xi/d\lambda = \xi t$. For radiative correction to muon polarization in $K^{\pm}_{\mu3}$, see GINSBERG 71. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

−0.017±0.011			[100] BRAUN	74	HLBC	+	$K_{\mu3}/K_{e3}$ vs. t

[95] HEINTZE 77 uses $\lambda_+ = 0.029 \pm 0.003$. $d\lambda_0/d\lambda_+$ estimated by us.

[96] λ_0 value is for $\lambda_+ = 0.03$ calculated by us from $\xi(0)$ and $d\xi(0)/d\lambda_+$.

[97] MERLAN 74 λ_0 and $d\lambda_0/d\lambda_+$ were calculated by us from ξ_A, λ_+^μ, and $d\xi(0)/d\lambda_+$. Their figure 6 gives $\lambda_0 = -0.025 \pm 0.012$ and no $d\lambda_0/d\lambda_+$.

[98] This value and error are taken from BRAUN 75 but correspond to the BRAUN 73C λ_+^μ result. $d\lambda_0/d\lambda_+$ is from BRAUN 73C $d\xi(0)/d\lambda_+$ in ξ_A above.

[99] λ_0 calculated by us from $\xi(0)$, λ_+^μ, and $d\xi(0)/d\lambda_+$.

[100] BRAUN 74 is a combined $K_{\mu3}$-K_{e3} result. It is not independent of BRAUN 73C ($K_{\mu3}$) and BRAUN 73B (K_{e3}) form factor results.

f_T/f_+ FOR $K^{\pm}_{\mu3}$ DECAY

Ratio of tensor to f_+ couplings.

VALUE	EVTS	DOCUMENT ID		TECN
0.02±0.12	1585	BRAUN	75	HLBC

See key on page 1343

DECAY FORM FACTORS FOR $K^{\pm} \to \pi^+\pi^- e^{\pm}\nu_e$

Given in ROSSELET 77, BEIER 73, and BASILE 71C.

DECAY FORM FACTOR FOR $K^{\pm} \to \pi^0\pi^0 e^{\pm}\nu$

Given in BOLOTOV 86B and BARMIN 88B.

$K^{\pm} \to \ell^{\pm}\nu\gamma$ FORM FACTORS

For definitions of the axial-vector F_A and vector F_V form factor, see the "Note on $\pi^{\pm} \to \ell^{\pm}\nu\gamma$ and $K^{\pm} \to \ell^{\pm}\nu\gamma$ Form Factors" in the $\pi^{\pm}$ section. In the kaon literature, often different definitions $a_K = F_A/m_K$ and $v_K = F_V/m_K$ are used.

$F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to e\nu_e\gamma$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.148±0.010 OUR AVERAGE					
0.147±0.011	51	[101] HEINTZE	79	SPEC	$K \to e\nu\gamma$
$0.150^{+0.018}_{-0.023}$	56	[102] HEARD	75	SPEC	$K \to e\nu\gamma$

[101] HEINTZE 79 quotes absolute value of $|F_A + F_V|\ \sin\theta_c$. We use $\sin\theta_c = V_{us} = 0.2205$.

[102] HEARD 75 quotes absolute value of $|F_A + F_V|\ \sin\theta_c$. We use $\sin\theta_c = V_{us} = 0.2205$.

$F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to \mu\nu_\mu\gamma$

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
< 0.23	90	[103] AKIBA	85	SPEC	$K \to \mu\nu\gamma$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
−1.2 to 1.1	90	DEMIDOV	90	XEBC	$K \to \mu\nu\gamma$

[103] AKIBA 85 quotes absolute value.

$F_A - F_V$, DIFFERENCE OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to e\nu_e\gamma$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
<0.49	90	[104] HEINTZE	79	SPEC	$K \to e\nu\gamma$

[104] HEINTZE 79 quotes $|F_A - F_V| < \sqrt{11}\,|F_A + F_V|$.

$F_A - F_V$, DIFFERENCE OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to \mu\nu_\mu\gamma$

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
−2.2 to 0.3 OUR EVALUATION					
−2.2 to 0.6	90	DEMIDOV	90	XEBC	$K \to \mu\nu\gamma$
−2.5 to 0.3	90	AKIBA	85	SPEC	$K \to \mu\nu\gamma$

[1] CARITHERS 75 value is for $m_{K^0_L} - m_{K^0_S}$ $\Delta(m) = 0.5348 \pm 0.0021$. The $\Delta(m)$ dependence of the total decay rate (inverse mean life) is $\Gamma(K^0_S) = [(1.122 \pm 0.004) + 0.16(\Delta(m) - 0.5348)/\Delta(m)]10^{10}$/s. Value would not change with our current $\Delta(m) = 0.5349 \pm 0.0022$.

[2] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

[3] ARONSON 82 find that K^0_S mean life may depend on the kaon energy.

[4] FACKLER 73 does not include systematic errors.

[5] Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

[6] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[c] Calculated from K^0_L semileptonic rates and the K^0_S lifetime assuming $\Delta S = \Delta Q$.

See key on page 1343

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 17 measurements and one constraint to determine 2 parameters. The overall fit has a χ^2 = 16.5 for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

NOTE ON CP VIOLATION IN $K_S \to 3\pi$

(by T. Nakada, Paul Scherrer Institute and L. Wolfenstein, Carnegie-Mellon University)

The possible final states for the decay $K^0 \to \pi^+\pi^-\pi^0$ have isospin $I = 0$, 1, 2, and 3. The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \to \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \to \pi^+\pi^-\pi^0)}{A(K_L \to \pi^+\pi^-\pi^0)} .$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \to \pi^0\pi^0\pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0}, η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \to \pi^0\pi^0\pi^0)}{A(K_L \to \pi^0\pi^0\pi^0)} .$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\eta_{+-0} = \eta_{000} = \epsilon + i\frac{\mathrm{Im}\ a_1}{\mathrm{Re}\ a_1} .$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \to 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\mathrm{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\mathrm{Im}(\eta_{+-0})$ and $\mathrm{Im}(\eta_{000})$.

CP-VIOLATION PARAMETERS IN K^0_S DECAY

$\mathrm{Im}(\eta_{+-0})^2 = \Gamma(K^0_S \to \pi^+\pi^-\pi^0, CP\text{-violating}) / \Gamma(K^0_L \to \pi^+\pi^-\pi^0)$

CPT assumed valid (i.e. $\mathrm{Re}(\eta_{+-0}) \simeq 0$).

<0.28	90		[22] GJESDAL	74B	SPEC	Indirect meas.
<1.2	90	22	BARMIN	73	HLBC	

[21] BARMIN 83 find $\mathrm{Re}(\eta_{000}) = (-0.08 \pm 0.18)$ and $\mathrm{Im}(\eta_{000}) = (-0.05 \pm 0.27)$. Assuming CPT invariance they obtain the limit quoted above.

[22] GJESDAL 74B uses $K2\pi$, $K_{\mu 3}$, and K_{e3} decay results, unitarity, and CPT. Calculates $|(\eta_{000})| = 0.26 \pm 0.20$. We convert to upper limit.

K^0_L

$I(J^P) = \frac{1}{2}(0^-)$

$m_{K^0_L} - m_{K^0_S}$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our our 1986 edition, Physics Letters **170B** 132 (1986).

[1] GIBBONS 93C fits $\Delta(m)$ and ϕ_{+-}. Finds above $\Delta(m)$ and $\phi_{+-} = (42.2 \pm 1.4)^\circ$.

[2] These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.

[3] GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$.

[4] ARONSON 82 find that $\Delta(m)$ may depend on the kaon energy.

[5] ARONSON 70 and CARNEGIE 71 use K^0_S mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K^0_S mean life or in η_{+-}.

Γ_{28}	$\pi^0\nu\overline{\nu}$	$CP,S1$ [f]	< 2.2 × 10^{-4}	CL=90%
Γ_{29}	$e^\pm\mu^\mp$	LF [a]	< 3.3 × 10^{-11}	CL=90%

[a] The value is for the sum of the charge states indicated.

[b] See the Full Listings below for the energy limits used in this measurement.

[c] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[d] $m_{e^+e^-}$ >470 MeV

[e] Allowed by higher-order electroweak interactions.

[f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, 4 decay rate, and 12 branching ratios uses 53 measurements and one constraint to determine 8 parameters. The overall fit has a χ^2 = 55.3 for 46 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

3.26±0.77	18	ANDERSON	65	HBC	
1.4 ±0.4	14	FRANZINI	65	HBC	

In the fit this rate is well determined by the mean life and the branching ratio $\Gamma(\pi^+\pi^-\pi^0)/\left[\Gamma(\pi^+\pi^-\pi^0) + \Gamma(\pi^\pm\mu^\mp\nu) + \Gamma(\pi^\pm e^\mp\nu)\right]$. For this reason the discrepancy between the $\Gamma(\pi^+\pi^-\pi^0)$ measurements does not affect the scale factor of the overall fit.

[7] JAMES 72 is a final measurement and includes JAMES 71.

K^0_L FORM FACTORS

For discussion, see note on form factors in the $K^\pm$ section of the Full Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$f_0 = f_+ + f_- t/(m^2_K - m^2_\pi)$.

λ_+, λ_-, and λ_0 are the linear expansion coefficients of f_+, f_-, and f_0.

λ_+ refers to the $K^0_{\mu 3}$ value except in the K^0_{e3} sections.

$d\xi(0)/d\lambda_+$ is the correlation between $\xi(0)$ and λ_+ in $K^0_{\mu 3}$.

$d\lambda_0/d\lambda_+$ is the correlation between λ_0 and λ_+ in $K^0_{\mu 3}$.

t = momentum transfer to the π in units of m^2_π.

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL= μ polarization analysis.

BR = $K^0_{\mu 3}/K^0_{e3}$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K^0_{e3} DECAY)

For radiative correction of K^0_{e3} DP, see GINSBERG 67 and BECHERRAWY 70.

−3.9 ±0.4		3140	[67] BASILE	70	OSPK	DP, indep of λ_+
$-0.68\ ^{+0.12}_{-0.20}$	−26	16k	[66] CHIEN	70	ASPK	DP

[59] BIRULEV 81 error, $d\xi(0)/d\lambda_+$ calculated by us from λ_0, λ_+. $d\lambda_0/d\lambda_+ = 0$ used.

[60] HILL 79 and CHO 80 calculated by us from λ_0, λ_+, and $d\lambda_0/d\lambda_+$.

[61] BUCHANAN 75 is calculated by us from λ_0, λ_+ and $d\lambda_0/d\lambda_+$ because their appendix A value -0.20 ± 22 assumes $\xi(t)$ constant, i.e. $\lambda_- = \lambda_+$.

[62] DONALDSON 74B gives $\xi = -0.11 \pm 0.02$ not including systematics. Above error and $d\xi(0)/d\lambda_+$ were calculated by us from λ_0 and λ_+ errors (which include systematics) and $d\lambda_0/d\lambda_+$.

[63] PEACH 73 gives $\xi(0) = -0.95 \pm 0.45$ for $\lambda_+ = \lambda_- = 0.025$. The above value is for $\lambda_- = 0$. K.Peach, private communication (1974).

[64] ALBROW 72 fit has λ_- free, gets $\lambda_- = -0.030 \pm 0.060$ or $\Lambda = +0.15\ ^{+0.17}_{-0.11}$.

[65] CARPENTER 66 $\xi(0)$ is for $\lambda_+ = 0$. $d\xi(0)/d\lambda_+$ is from figure 9.

[66] CHIEN 70 errors are statistical only. $d\xi(0)/d\lambda_+$ from figure 4. DALLY 72 is a reanalysis of CHIEN 70. The DALLY 72 result is not compatible with assumption $\lambda_- = 0$ so not included in our fit. The nonzero λ_- value and the relatively large λ_+ value found by DALLY 72 come mainly from a single low t bin (figures 1,2). The (f_+, ξ) correlation was ignored. We estimate from figure 2 that fixing $\lambda_- = 0$ would give $\xi(0) = -1.4 \pm 0.3$ and would add 10 to χ^2. $d\xi(0)/d\lambda_+$ is not given.

[67] BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

$\xi_b = f_-/f_+$ (determined from $K^0_{\mu 3}/K^0_{e3}$)

The $K^0_{\mu 3}/K^0_{e3}$ branching ratio fixes a relationship between $\xi(0)$ and λ_+. We quote the author's $\xi(0)$ and associated λ_+ but do not average because the λ_+ values differ. The fit result and scale factor given below are not obtained from these ξ_b values. Instead they are obtained directly from the authors $K^0_{\mu 3}/K^0_{e3}$ branching ratio via the fitted $K^0_{\mu 3}/K^0_{e3}$ ratio $(\Gamma(\pi^\pm \mu^\mp \nu)/\Gamma(\pi^\pm e^\mp \nu))$. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

[68] EVANS 73 replaces EVANS 69.

$\xi_c = f_-/f_+$ (determined from μ polarization in $K^0_{\mu 3}$)

The μ polarization is a measure of $\xi(t)$. No assumptions on λ_{+-} necessary, t (weighted by sensitivity to $\xi(t)$) should be specified. In λ_+, $\xi(0)$ parametrization this is $\xi(0)$ for $\lambda_+ = 0$. $d\xi/d\lambda = \xi t$. For radiative correction to μ polarization in $K^0_{\mu 3}$, see GINSBERG 73. The parameter ξ is redundant with λ_0 below and is not put into the Meson Summary Table.

[75] BIRULEV 81 gives $d\lambda_0/d\lambda_+ = -1.5$, giving an unreasonably narrow error ellipse which dominates all other results. We use $d\lambda_0/d\lambda_+ = 0$.

[76] λ_0 value is for $\lambda_+ = 0.03$ calculated by us from ξ(0) and $d\xi(0)/d\lambda_+$.

[77] BUCHANAN 75 value is from their appendix A and uses only $K_{\mu 3}$ data. $d\lambda_0/d\lambda_+$ was obtained by private communication, C.Buchanan, 1976.

[78] DONALDSON 74B $d\lambda_0/d\lambda_+$ obtained from figure 18.

[79] PEACH 73 assumes $\lambda_+ = 0.025$. Calculated by us from ξ(0) and $d\xi(0)/d\lambda_+$.

[80] ALBROW 72 λ_0 is calculated by us from ξ_A, λ_+ and $d\xi(0)/d\lambda_+$. They give $\lambda_0 = -0.043 \pm 0.039$ for $\lambda_- = 0$. We use our larger calculated error.

[81] CHO 80 BR result not independent of their Dalitz plot result.

[82] Fit for λ_0 does not include this value but instead includes the $K_{\mu 3}/K_{e3}$ result from this experiment.

[83] DALLY 72 gives $f_0 = 1.20 \pm 0.35$, $\lambda_0 = -0.080 \pm 0.272$, $\lambda_0' = -0.006 \pm 0.045$, but with a different definition of λ_0. Our quoted λ_0 is his λ_0/f_0. We cannot calculate true λ_0 error without his (λ_0, f_0) correlations. See also note on DALLY 72 in section ξ_A.

[84] BASILE 70 λ_0 is for $\lambda_+ = 0$. Calculated by us from ξ_A with $d\xi(0)/d\lambda_+ = 0$. BASILE 70 is incompatible with all other results. Authors suggest that efficiency estimates might be responsible.

α_{K^*} DECAY FORM FACTOR FOR $K_L \to e^+e^-\gamma$

α_{K^*} is the constant in the model of BERGSTROM 83 which measures the relative strength of the vector-vector transition $K_L \to K^*\gamma$ with $K^* \to \rho, \omega, \phi \to \gamma^*$ and the pseudoscalar-pseudoscalar transition $K_L \to \pi, \eta, \eta' \to \gamma\gamma^*$.

DECAY FORM FACTORS FOR $K^0_L \to \pi^\pm\pi^0 e^\mp \nu_e$

Given in MAKOFF 93.

NOTE ON CP VIOLATION IN K^0_L DECAY

(by L. Wolfenstein, Carnegie-Mellon University and T. Trippe, LBL)

Experimentally Measured Parameters

CP violation has been observed in the semi-leptonic decays $K^0_L \to \pi^\mp \ell^\pm \nu$ and in the nonleptonic decay $K^0_L \to 2\pi$. The experimental numbers that have been measured are [1]

$$\delta = \frac{\Gamma(K^0_L \to \pi^-\ell^+\nu) - \Gamma(K^0_L \to \pi^+\ell^-\nu)}{\Gamma(K^0_L \to \pi^-\ell^+\nu) + \Gamma(K^0_L \to \pi^+\ell^-\nu)} \tag{1a}$$

$$\eta_{+-} = A(K^0_L \to \pi^+\pi^-)/A(K^0_S \to \pi^+\pi^-)$$
$$= |\eta_{+-}|\, e^{i\phi_{+-}} \tag{1b}$$

$$\eta_{00} = A(K^0_L \to \pi^0\pi^0)/A(K^0_S \to \pi^0\pi^0)$$
$$= |\eta_{00}|\, e^{i\phi_{00}} \ . \tag{1c}$$

Thus there are five real numbers, three magnitudes, and two phases. We list $\delta(\mu)$ for $K^0_L \to \pi\mu\nu$ and $\delta(e)$ for $K^0_L \to \pi e\nu$ separately and a weighted average δ. Experimentally for the $K^0_L \to \pi^0\pi^0$ decay the quantities directly measured (and also of greatest theoretical interest) are $|\eta_{00}/\eta_{+-}|$ and $\phi_{00} - \phi_{+-}$.

Analysis Based on CPT Invariance [2]

CP violation can occur either in the $K^0 - \overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the CP

violation in the mixing is described by a single parameter ϵ:

$$| K_L^0\rangle = \left[(1+\epsilon) \mid K^0\rangle - (1-\epsilon) \mid \overline{K}^0\rangle\right] / \left[2(1+\mid\epsilon\mid^2)\right]^{1/2} \quad (2a)$$

$$| K_S^0\rangle = \left[(1+\epsilon) \mid K^0\rangle + (1-\epsilon) \mid \overline{K}^0\rangle\right] / \left[2(1+\mid\epsilon\mid^2)\right]^{1/2} \ . \quad (2b)$$

The decay amplitudes are written

$$\langle\, I=0 \mid T \mid K^0\rangle = e^{i\delta_0} A_0 \quad (3a)$$

$$\langle\, I=2 \mid T \mid K^0\rangle = e^{i\delta_2} A_2 \quad (3b)$$

where δ_I are the $\pi\pi$ scattering phase shifts at the K^0 mass and I is the isospin of the final state. CP violation is measured by (Im A_I/Re A_I). One can then write

$$\eta_{+-} = \epsilon + \epsilon' \quad (4a)$$

$$\eta_{00} = \epsilon - 2\epsilon' \quad (4b)$$

where

$$\epsilon' = \frac{i}{\sqrt{2}}\, e^{i(\delta_2-\delta_0)}\, \frac{\text{Re } A_2}{\text{Re } A_0} \left[\frac{\text{Im } A_2}{\text{Re } A_2} - \frac{\text{Im } A_0}{\text{Re } A_0}\right] \quad (5)$$

neglecting small corrections of order ϵ' times Re(A_2/A_0). Only two of the three quantities ϵ, (Im A_I/Re A_I) are meaningful because of the ambiguity in defining the phase of K^0. The standard phase convention due to Wu and Yang [3] sets Im $A_0 = 0$. A nonzero value of ϵ' would provide definite evidence for CP violation in the decay amplitudes independent of phase convention.

By applying CPT invariance and unitarity it is possible to relate δ to ϵ and to determine the phases of ϵ. If one assumes the $\Delta S = \Delta Q$ rule (see below "Note on the $\Delta S = \Delta Q$ rule in K^0 Decay") the expression for δ becomes

$$\delta = 2\text{Re}\,\epsilon/(1+\mid\epsilon\mid^2) \approx 2\text{Re}\,\epsilon \ . \quad (6)$$

This quantity is independent of phase convention and is seen from Eq. (2) to equal $\langle K_L^0 \mid K_S^0\rangle$. The phase of ϵ is given by

$$\phi(\epsilon) \approx \tan^{-1}\frac{(2\Delta m \tau_s)}{\hbar} = 43.59 \pm 0.15^\circ \quad (7a)$$

while Eq. (5) gives

$$\phi(\epsilon') = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 48 \pm 4^\circ \ . \quad (7b)$$

The approximation in Eq. (7a) depends on the neglect of CP violation in decays other than $K^0 \to 2\pi$ and is known to be good to a few tenths of a degree. Eq. (7a) is evaluated using the values of the $K_L^0 - K_S^0$ mass difference $\Delta m = (0.5333 \pm 0.0027) \times 10^{10}\hbar\text{s}^{-1}$ and the K_S^0 mean life $\tau_s = (0.8926 \pm 0.0012) \times 10^{-10}$s from the current edition. The value of the $\pi\pi$ phase shifts is taken from the fit given by Chell and Olsson [4]. The most important point for the analysis is that $\cos[\phi(\epsilon') - \phi(\epsilon)] \simeq 1$. The consequence of this analysis is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ which is very close to unity, is given to a good approximation by

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}\,(\epsilon'/\epsilon) = 1 - 6(\epsilon'/\epsilon)\cos[\phi(\epsilon') - \phi(\epsilon)] \ . \quad (8)$$

Since the cos in Eq. (8) is expected theoretically to be very close to unity it is customary to say that $|\eta_{00}/\eta_{+-}|^2$ determines ϵ'/ϵ.

It is possible to use the values of the ϕ_{+-} and $\phi_{00} - \phi_{+-}$ to set limits on CPT violation. [See Tests of Conservation Laws.]

Models

In the superweak model [5] CP violation is restricted to the mass mixing so that to a high degree of accuracy one expects $\epsilon' = 0$. The phase $\phi(\epsilon)$ is given in this model exactly by Eq. (7a) so that this has sometimes been referred to as the superweak phase; however, as noted above, all CPT invariant models give Eq. (7a) as a very good approximation. In the Standard Model CP violation is entirely due to the phase in the Cabibbo-Kobayashi-Maskawa mixing matrix [6](q.v.). Since CP violation occurs in first order in decay amplitudes and in second order in mass-matrix mixing, one expects a significant nonzero value of ϵ'. The calculation is uncertain partly because m_t and V_{td} are not well known and primarily because of the difficulty of estimating hadronic matrix elements [7]. The theoretical results for ϵ'/ϵ in the standard model are generally in the range 3×10^{-4} to 5×10^{-3}, but may be even lower for large values of m_t.

Fitting procedures

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, and $|\eta_{00}/\eta_{+-}|$. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes (τ) and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{\text{B}(K_L^0 \to \pi^+\pi^-)}{\tau(K_L^0)}\, \frac{\tau(K_S^0)}{\text{B}(K_S^0 \to \pi^+\pi^-)}\right]^{1/2} \ , \quad (9a)$$

$$|\eta_{00}| = \left[\frac{\text{B}(K_L^0 \to \pi^0\pi^0)}{\tau(K_L^0)}\, \frac{\tau(K_S^0)}{\text{B}(K_S^0 \to \pi^0\pi^0)}\right]^{1/2} \ . \quad (9b)$$

We approximate a global fit to these independent sources by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, and $|\eta_{+-}/\eta_{00}|$ measurements. The results from fit 1, along with the K_S^0 values from this edition are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$ which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 94. Thus the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from

fit 2 above (before including BRFIT 94 values) are used along with the K^0_L and K^0_S mean lives and the $K^0_S \to \pi\pi$ branching fractions to compute the K^0_L branching ratios $\Gamma(K^0_L \to \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K^0_L \to \pi^0\pi^0)/\Gamma(K^0_L \to \pi^+\pi^-)$. These branching ratio values are included as measurements in the branching ratio section with a document ID of ETAFIT 94. Thus the K^0_L branching ratio fit values in this edition include the results of direct measurements of $|\eta_{+-}|$, $|\eta_{00}|$, and $|\eta_{00}/\eta_{+-}|$. Details of these fits are given in the 1990 edition of this *Review* [8].

Since the last edition, results on ϵ'/ϵ have been published by CERN NA31 (BARR 93D) and Fermilab E731 (GIBBONS 93B). These results dominate our fit to ϵ'/ϵ, $|\eta_{+-}|$, $|\eta_{00}|$, and $B(K_L \to \pi\pi)$. The resulting value $\epsilon'/\epsilon = (1.5 \pm 0.8) \times 10^{-3}$ (S = 1.8) has a large scale factor S included in the error, indicating a continuing disagreement in the input data. The CERN NA31 result continues to indicate the presence of direct CP violation with a result which is more than three σ above zero while the Fermilab E731 result is consistent with zero.

The Fermilab E731 experiment also has published recent results on ϕ_{+-}, $\phi_{00}-\phi_{+-}$, and Δm. GIBBONS 93 reports $\Delta m = (0.5286 \pm 0.0028) \times 10^{10}\ \hbar\ s^{-1}$ assuming $\phi_{+-} = \phi_{00} = \phi_{SW}$. GIBBONS 93C reports $\Delta m = (0.5257 \pm 0.0049) \times 10^{10}\ \hbar\ s^{-1}$ when a joint fit with ϕ_{+-} is done. We use this value in our average rather than the GIBBONS 93 value to avoid the ϕ_{SW} constraint. This is so that when we reevaluate ϕ_{+-} experiments using our average Δm, we will avoid biasing ϕ_{+-} toward ϕ_{SW} The resulting average $\Delta m = (0.5333 \pm 0.0027) \times 10^{10}\ \hbar\ s^{-1}$ (S = 1.2) is $0.0018 \times 10^{10}\ \hbar\ s^{-1}$ lower than our 1992 average as a result of the lower E731 value. GIBBONS 93 reports $\phi_{+-} = 42.2 \pm 1.4°$ for their Δm and τ_s. We use their Δm and τ_s dependence quoted in NAKADA 93. We revaluate all ϕ_{+-} measurements for the current Δm and τ_s PDG averages. The resulting value $\phi_{+-} = 44.3 \pm 0.8°$ is two old standard deviations below our 1992 average and is now consistent with the "superweak" phase given in Eq. (7a).

PARAMETERS FOR $K^0_L \to 2\pi$ DECAY

$\eta_{+-} = A(K^0_L \to \pi^+\pi^-) / A(K^0_S \to \pi^+\pi^-)$
$\eta_{00} = A(K^0_L \to \pi^0\pi^0) / A(K^0_S \to \pi^0\pi^0)$

The fitted values of $|\eta_{+-}|$ and $|\eta_{00}|$ given below are the results of a fit to $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and Re(ϵ'/ϵ). Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from the fitted values of the $K^0_L \to \pi\pi$ and $K^0_S \to \pi\pi$ branching ratios and the K^0_L and K^0_S lifetimes. This information is included as data in the $|\eta_{+-}|$ and $|\eta_{00}|$ sections with a Document ID "BRFIT." See the "Note on CP Violation in K^0_L Decay" above for details.

$|\eta_{00}| = |A(K^0_L \to 2\pi^0) / A(K^0_S \to 2\pi^0)|$

2.09 ±0.02		[91] ARONSON	82B	SPEC	E=30–110 GeV

[89] This BRFIT value is computed from fitted values of the K^0_L and K^0_S lifetimes and branching fractions to $\pi\pi$. See the discussion in the "Note on CP violation in K^0_L decay."

[90] COUPAL 85 concludes: no energy dependence of $|\eta_{+-}|$, because their value is consistent with above values which occur at lower energies. Not independent of COUPAL 85 $\Gamma(\pi^+\pi^-)/\Gamma(\pi\ell\nu)$ measurement. Enters $|\eta_{+-}|$ via BRFIT value. In editions prior to 1990, this measurement was erroneously also included in our $|\eta_{+-}|$ average and fit. We thank H. Wahl (WAHL 89) for informing us.

[91] ARONSON 82B find that $|\eta_{+-}|$ may depend on the kaon energy.

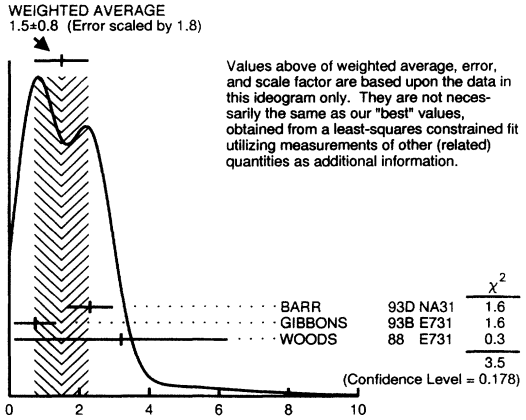
[92] This is the square root of the ratio R given by BURKHARDT 88 and BARR 93D.

[93] This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

[94] We calculate $|\eta_{00}/\eta_{+-}| = 1-3(\epsilon'/\epsilon)$ from WOODS 88 (ϵ'/ϵ) value.



[95] Not independent of $|\eta_{+-}|$ and $|\eta_{00}|$ values which are included in fit.

$\epsilon'/\epsilon \approx \mathrm{Re}(\epsilon'/\epsilon) = (1-|\eta_{00}/\eta_{+-}|)/3$

[96] This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

[97] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ section only.

$\epsilon'/\epsilon \approx \mathrm{Re}(\epsilon'/\epsilon) = (1-|\eta_{00}/\eta_{+-}|)/3$

ϕ_{+-}, PHASE of η_{+-}

The dependence of the phase on the $m_{K^0_L} - m_{K^0_S}$ is given for each experiment in the comments below, where $\Delta(m)$ is (mass difference/$\hbar$) in units 10^{10} s^{-1} and τ_S is the K_S mean life in units 10^{-10} s. We have evaluated these mass dependences using our 1994 values, $\Delta(m) = 0.5333 \pm 0.0027$, $\tau_S = 0.8926 \pm 0.0012$ to obtain the values and average quoted below. We also give the regeneration phase ϕ_f in the comments below.

[98] GIBBONS 93 measures $\phi_+ - \phi_f$ and calculates the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase. They find $\phi_{+-} = 42.21 \pm 0.9 + 189\,[\Delta(m) - 0.5286] - 460\,[\tau_S - 0.8922]°$. B. Winstein, private communication, reported in NAKADA 93. GIBBONS 93 reports ϕ_{+-} (42.2 ± 1.4)° for their $\Delta(m)$ and τ_S.

[99] ADLER 92B quote separately two systematic errors: ±0.4 from their experiment and ±1.0 degrees due to the uncertainty in the value of $\Delta(m)$.

[100] CAROSI 90 $\phi_{+-} = 46.9 \pm 1.4 \pm 0.7 + 579\,[\Delta(m) - 0.5351] + 303\,[\tau_S - 0.8922]°$.

[101] CARITHERS 75 $\phi_{+-} = (45.5 \pm 2.8) + 224[\Delta(m) - 0.5348]°$. $\phi_f = -40.9 \pm 2.6°$.

[102] GEWENIGER 74B $\phi_{+-} = (49.4 \pm 1.0) + 565[\Delta(m) - 0.540]°$.

[103] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

[104] ARONSON 82 find that ϕ_{+-} may depend on the kaon energy.

[105] CARNEGIE 72 ϕ_{+-} is insensitive to $\Delta(m)$. $\phi_f = -56.2 \pm 5.2°$.

[106] BALATS 71 $\phi_{+-} = (39.0 \pm 12.0) + 198[\Delta(m) - 0.544]°$. $\phi_f = -43.0 \pm 4.0°$.

[107] JENSEN 70 $\phi_{+-} = (42.4 \pm 4.0) + 576[\Delta(m) - 0.538]°$.

[108] BENNETT 69 uses measurement of $(\phi_{+-}) - (\phi_f)$ of ALFF-STEINBERGER 66B. BENNETT 69 $\phi_{+-} = (34.9 \pm 10.0) + 69[\Delta(m) - 0.545]°$. $\phi_f = -49.9 \pm 5.4°$.

[109] BOHM 69B $\phi_{+-} = (41.0 \pm 12.0) + 479(\Delta(m) - 0.526)°$.

[110] FAISSNER 69 error enlarged to include error in regenerator phase. FAISSNER 69 $\phi_{+-} = (49.3 \pm 7.4) + 205[\Delta(m) - 0.555]°$. $\phi_f = -42.7 \pm 5.0°$.

[111] BENNETT 69 is a re-evaluation of BENNETT 68B.

[112] Old experiments with large errors not included in average.

ϕ_{00}, PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of $\Delta(m)$ and τ_S dependence.

[120] RAMBERG 93B limit on $|\epsilon'_{+-\gamma}|/\epsilon$ assumes than any difference between η_{+-} and $\eta_{+-\gamma}$ is due to direct CP violation.

NOTE ON $\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu) .$$

We list $\mathrm{Re}\{x\}$ and $\mathrm{Im}\{x\}$ for K_{e3} and $K_{\mu3}$ combined.

$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu) = A(\Delta S{=}{-}\Delta Q)/A(\Delta S{=}\Delta Q)$

[1] From a partial wave amplitude analysis.
[2] Inclusive reaction. Complicated background and phase-space effects.
[3] Mass errors enlarged by us to $\Gamma/\sqrt{N}$. See note.
[4] Number of events in peak reevaluated by us.
[5] From pole extrapolation.

NOTE ON $K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors are reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4\frac{\Gamma}{\sqrt{N}} .$$

(For a detailed discussion, see the 1971 edition of this note.) We consistently increase unrealistic errors before averaging.

$m_{K^*(892)^0} - m_{K^*(892)^\pm}$

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 18 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 15.2$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 28 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 19.5$ for 21 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−36	
x_3	−39	−72
	x_1	x_2

$K_2(1770)$ was $L(1770)$

$I(J^P) = \frac{1}{2}(2^-)$

NOTE ON THE $K_2(1770)$ AND THE $K_2(1820)$

A partial-wave analysis of the $K^-\omega$ system based on about 100,000 $K^-p \to K^-\omega p$ events (ASTON 93) provides evidence for two $q\bar{q}$ D-wave states near 1.8 GeV. A previous analysis based on about 200,000 diffractively produced $K^-p \to K^-\pi^+\pi^-p$ events (DAUM 81) gave evidence for two $J^P = 2^-$ states in this region, with masses $\sim$ 1780 MeV and $\sim$ 1840 MeV and widths $\sim$ 200 MeV, in good agreement with ASTON 93. In contrast, the masses obtained using a single resonance do not agree well: ASTON 93 obtains 1728 ± 7 MeV, while DAUM 81 estimates $\sim$ 1820 MeV.

We list under the $K_2(1770)$ other measurements that do not resolve the two-resonance structure of the enhancement (previously called $L(1770)$).

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 2.2$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

NOTE ON D MESON BRANCHING FRACTIONS

(by R.H. Schindler, SLAC)

This edition strongly reflects the impact that CLEO-II has had on charm meson physics in the last two years. The CESR-II luminosity for data taken at the $\Upsilon(4S)$ resonance and in the nearby e^+e^- continuum since startup in 1991 has climbed to $\sim 15\text{pb}^{-1}$/day and has totaled more than 2 fb^{-1}. In addition, this edition includes the first high-statistics results of the next (post-E691) generation of fixed-target experiments at FNAL (E653, E687). We anticipate that the CLEO-II and the FNAL fixed-target programs will continue to dominate the field through the end of the decade. The BES program for charmed physics is now also underway, and its first results should appear within the next year.

In this edition, we have restructured the Full Listings to further clarify and reduce the uncertainty in the normalization of the charmed D^+, D^0, and D_s^+ branching fractions. We continue to enter only experimentally measured quantities and not derived quantities, except where noted. All experiments measuring ratios of branching fractions are included in our calculations. (We shall call $B_1 = \Gamma_1/\Gamma_{\text{total}}$ a branching *fraction*, and Γ_1/Γ_2 a branching *ratio*.) These are usually measurements of branching fractions relative to the most accessible channels, such as $K^-\pi^+\pi^+$ for the D^+, $K^-\pi^+$ and $K^-\pi^+\pi^+\pi^-$ for the D^0, and $\phi\pi^+$ for the D_s^+. The problem is to set the absolute scales for the branching fractions.

In our 1992 edition, we combined results from several experimental methods to set the scale of branching fractions of D^+ and D^0 mesons. One source was the direct measurements of the D^+ and D^0 branching fractions as reported in BALTRUSAITUS 86 and subsequently updated in ADLER 88C, using data at the $\psi(3770)$ resonance. In the latter paper, the rates of observed production of single charm and pairs of charm particles were compared to establish the absolute branching fraction scale. A second source was the results from topologically normalized experiments (*e.g.*, AGUILAR-BENITEZ 84) and other so-called "double tagging" techniques (*e.g.*, BARLAG 90D). A third source was measurements from ALEPH of the D^0 absolute branching fraction (DECAMP 91) using the technique pioneered by HRS (ABACHI 88) applied to D^* from Z decays. This technique compares the total rate for $Z \to D^{*+}\text{X}$ followed by $D^{*+} \to D^0\pi^+$, measured by observing only the soft low Q-value π^+, with the total rate for $Z \to D^{*+}\text{X}$ followed by $D^{*+} \to D^0\pi^+$ and then $D^0 \to K^-\pi^+$.

In this edition, we have revisited the question, in the light of new measurements of the D^+ and D^0 branching fractions from CLEO-II. In AKERIB 93, CLEO-II measures the $D^0 \to K^-\pi^+$ branching fraction as $(3.91 \pm 0.08 \pm 0.17)\%$, in excellent agreement with the previous e^+e^- results at the $\psi(3770)$ and the Z but with better precision. In BALEST 94, CLEO-II uses a similar technique applied to the D^{*0} to measure the branching fraction $D^+ \to K^-\pi^+\pi^+$ to be $(9.3 \pm 0.6 \pm 0.8)\%$, with a precision comparable to the previous e^+e^- results at the $\psi(3770)$. In this edition, we use the direct measurements of branching fractions at the $\psi(3770)$ and the recent measurements using D^* decays, but remove the topological results from the averages and fits because of the uncertainty in the topological normalization and the inherent correlations with other measurements in the fitting procedure used to obtain them. The result is that the important $D^0 \to K^-\pi^+$ branching fraction is $(4.01 \pm 0.14)\%$ and the important $D^+ \to K^-\pi^+\pi^+$ branching fraction is $(9.1 \pm 0.6)\%$.

It may help to say a word about our averages and fits. An average is of (good) measurements of a single quantity, say of $\Gamma(D^0 \to K^-\pi^+)/\Gamma_{\text{total}}$. A fit involves two or more different quantities, say several different D^0 branching ratios. Our fits only include quantities that "push" against one another. For example, if there are measurements of $\Gamma_1/\Gamma_{\text{total}}$, $\Gamma_2/\Gamma_{\text{total}}$, and Γ_1/Γ_2, then these three quantities are included in the fit. But if Γ_3 only occurs in Γ_3/Γ_1, then $\Gamma_3/\Gamma_{\text{total}}$ is simply calculated from the fit value of $\Gamma_1/\Gamma_{\text{total}}$. Thus for the D^0, say, we determine all the different measured branching ratios that push against one another and include them in one big fit. (The correlation-coefficient matrix for this fit is right in front of the measurements of the branching ratios.) Since the sum of branching fractions included in the fit is less than unity, a "dummy" mode is added to account for modes absent. Once the overall fit is done, remaining branching fractions (of the sort $\Gamma_3/\Gamma_{\text{total}}$ mentioned above) are calculated from branching fractions obtained in the fit.

The absolute branching fraction scale for the D_s^+ is still quite uncertain. We anticipate in the near future a measurement at BES of the absolute branching fraction for $D_s^+ \to \phi\pi^+$, using the direct technique exploited first by MARK-III (*e.g.*, ADLER 90B). At present, we are constrained to rely on a set of experiments (ARGUS, CLEO, CLEO-II, and E687) that determine the ratio $\Gamma(D_s^+ \to \phi e^+\nu_e)/\Gamma(D_s^+ \to \phi\pi^+)$. The ratio $\Gamma(D_s^+ \to \phi e^+\nu_e)/\Gamma(D^+ \to \overline{K}^{*0}e^+\nu_e)$ is reliably calculated theoretically, and the experiments measure $\text{B}(D^+ \to \overline{K}^{*0}e^+\nu_e)$ and use the well-measured relative lifetimes (or total widths) of the D_s^+ and D^+ to then obtain $\text{B}(D_s^+ \to \phi\pi^+)$. We thus get $\text{B}(D_s^+ \to \phi\pi^\pm) = 3.5 \pm 0.4\%$ for normalizing the other decays.

A result of much theoretical interest is the measurement of the pseudoscalar weak decay constants (f_D) of the D_s^+ and the D^+. The decay constant measures the overlap of the heavy and light quark wave functions in the meson and is measured directly through the observation of pure leptonic decays of the D^+ or D_s^+ to $\mu^+\nu_\mu$ or $\tau^+\nu_\tau$. The precise value provides an unambiguous test of lattice QCD. The best limit on the D^+ decay constant was set by MARK-III (< 290 MeV at 90% CL). Two experiments, WA75 (AOKI 93) and CLEO-II

(ACOSTA 94) have published evidence for pure leptonic decays of the D_s^+. BES has also presented evidence in the form of a few events recoiling from tagged D_s^+ mesons in the 4-GeV region in e^+e^-. AOKI 93 claims 8 events in an emulsion experiment and finds a decay constant value of 232 MeV. CLEO-II finds about 39 events above background, corresponding to a decay constant of about 344 MeV. Both experiments have errors of about 75 MeV. The CLEO value is surprisingly large, but the error from the background subtraction and statistics still remains large. For further discussion, see also the "Note on Pseudoscalar-Meson Decay Constants" in the $\pi^\pm$ Full Listings.

See also the "Note on Semileptonic Decays of D and B Mesons" that follows for a review of the many new results in that area.

NOTE ON SEMILEPTONIC DECAYS OF D AND B MESONS, PART I

(by R.J. Morrison and J.D. Richman, University of California, Santa Barbara)

I. Introduction

Weak decays of heavy mesons are classified as hadronic, leptonic, or semileptonic, according to the type of particles present in the final state. The most complicated are hadronic decays, in which strong interactions produce nonperturbative effects that are difficult to calculate. In leptonic decays, the final state contains only a charged lepton and a neutrino; if the decaying meson is a pseudoscalar, the effects of strong interactions in the initial state can be parametrized by a single constant. (See the "Note on Pseudoscalar-Meson Decay Constants" in the $\pi^\pm$ Full Listings.) The rates for leptonic decay, however, are generally small and hard to measure.

Semileptonic decays are more tractable theoretically than hadronic decays, both because the $\ell\nu_\ell$ system produced by the virtual W boson is well understood, and because this system cannot have strong interactions with the hadronic decay products. In addition, semileptonic decay rates are reasonably large and experimentally accessible. As a consequence, semileptonic processes are the primary source of information on the Cabibbo-Kobayashi-Maskawa (CKM) matrix (see "The Cabibbo-Kobayashi-Maskawa Mixing Matrix," in Section 28 of the Reviews, Tables, Figures, and Formulae part of this *Review*).

In this Note, we discuss measurements of semileptonic decays of D and B mesons. These studies have two primary goals: first, to understand the dynamics of semileptonic decays, in particular, the effect of strong interactions on the underlying weak process; and second, to measure the magnitudes of the CKM elements V_{cb} and V_{ub}. These goals are related, because the determination of CKM elements relies on a good understanding of the decay process. Our discussion focuses on the sources of uncertainty in different types of measurements, especially the model dependence in the inclusive B semileptonic branching ratio and in the determination of $|V_{cb}|$ and $|V_{ub}|$.

The effects of strong interactions on the semileptonic decay amplitude can be expressed in terms of one or more Lorentz-invariant functions called form factors, which depend only on q^2, the square of the mass of the virtual W. The number of form factors required to describe a given exclusive decay depends on the quantum numbers of the hadrons in the decay. Information on the form factors is obtained by measuring the distributions of decay angles and q^2, as discussed in the following section.

In the charm sector, the absolute scale of theoretical predictions for decay amplitudes (expressed in terms of form factors) can be tested, because the CKM elements can be determined independently of the D semileptonic decay rate using the assumption of CKM unitarity and the smallness of the CKM elements for B decay. Thus, the study of D-meson semileptonic decays is concerned more with the size and q^2 dependence of the form factors than with the determination of CKM elements. However, studies of form factors in D semileptonic decays should provide theoretical information that will help to improve predictions for $b \to u\ \ell^-\overline{\nu}_\ell$ decays, and hence improve the determination of $|V_{ub}|$.

A development of major importance is the heavy quark effective theory (HQET). In the limit of infinite quark mass, the quark mass and spin decouple from the dynamics of the decay, leading to numerous symmetry relations among form factors. In this limit, the description of a process such as $B \to \overline{D}^*\ell^+\nu_\ell$ is simplified considerably, because both the b and c quarks are heavy. The form factors can then be related to a single universal form factor, the Isgur-Wise function. HQET predictions permit a systematic approach to understanding the dynamics of B-meson semileptonic decays and to determining the magnitudes of CKM elements. HQET predictions for D semileptonic decays are less useful, because symmetry-breaking corrections in this case are expected to be large.

We begin with a brief review of the formalism of form factors for exclusive semileptonic decays and then turn to experimental results on D and B mesons. More detailed information may be found in review articles on semileptonic decays and HQET [1,2,3].

II. Form-factor formalism for exclusive semileptonic decays

The amplitude for an exclusive semileptonic process can be constructed from the available four-vectors in the decay and from form factors, which are Lorentz invariant functions of q^2, the square of the mass of the virtual W. Because these functions describe the effect of strong interactions, nonperturbative techniques such as lattice QCD are needed to calculate them. Form factors are generally largest at the maximum value of q^2, where the daughter meson has the smallest recoil velocity and the overlap between the parent- and daughter-meson wave functions is largest. Studies of form factors in D semileptonic decays have focused on the modes $D \to \overline{K}\ell^+\nu_\ell$ and $D \to \overline{K}^*\ell^+\nu_\ell$, which dominate the inclusive semileptonic rate. In B decays, the analogous modes, $B \to \overline{D}\ell^+\nu_\ell$ and $B \to \overline{D}^*\ell^+\nu_\ell$, account for about two-thirds of the inclusive semileptonic rate. The decay $B \to \overline{D}\ell^+\nu_\ell$ has a large background from

$B \to \overline{D}^* \ell^+ \nu_\ell$, so in B decays, form factors have been studied only for $B \to \overline{D}^* \ell^+ \nu_\ell$. In this section, we discuss the formalism used in form-factor measurements for the decays $P \to P' \ell \nu_\ell$, where P and P' are pseudoscalar mesons, and $P \to V \ell \nu_\ell$, where V is a vector meson.

The differential decay rate for $P(Q\overline{q}) \to P'(q'\overline{q})\, \ell \nu_\ell$ is

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{q'Q}|^2 k_{P'}^3 |f_+(q^2)|^2}{24\pi^3} \ . \tag{1}$$

Here G_F is the Fermi decay constant, $V_{q'Q}$ is the relevant CKM matrix element, $k_{P'}$ is the momentum of P' in the rest frame of the parent meson, and $f_+(q^2)$ is a vector form factor. (Eq. (1) assumes massless charged leptons, which is almost exact for electrons and a very good approximation for muons, but it is not correct for τ's.) The dominant q^2 dependence comes from the p-wave factor $k_{P'}^3$, which can be written in terms of q^2 and the particle masses. This factor increases the rate at low q^2, which is opposite to the q^2 dependence of the form factor f_+.

The exclusive decay rate for $P \to V \ell \nu_\ell$ can be expressed in terms of three q^2-dependent helicity amplitudes, $H_\pm(q^2)$ and $H_0(q^2)$, where the subscripts indicate the helicity of either the virtual W or the vector meson. The rate is given by

$$\begin{aligned}\frac{d\Gamma}{dq^2\, d\cos\theta_\ell\, d\cos_V\, d\chi} = \frac{3G_F^2 |V_{q'Q}|^2\, k_V\, q^2}{8(4\pi)^4 M^2} \Big\{ & [(1+\eta\cos\theta_\ell)^2 |H_+(q^2)|^2 \\ & + (1-\eta\cos\theta_\ell)^2 |H_-(q^2)|^2] \sin^2\theta_V + 4\sin^2\theta_\ell \cos^2\theta_V |H_0(q^2)|^2 - 2\sin^2\theta_\ell \sin^2\theta_V \cos(2\chi) H_+(q^2) H_-(q^2) \\ & - 4\eta \sin\theta_\ell (1+\eta\cos\theta_\ell) \sin\theta_V \cos\theta_V \cos\chi\, H_+(q^2) H_0(q^2) + 4\eta \sin\theta_\ell (1-\eta\cos\theta_\ell) \sin\theta_V \cos\theta_V \cos\chi\, H_-(q^2) H_0(q^2) \Big\} \ . \end{aligned} \tag{2}$$

Here M is the mass of the parent meson, k_V is the momentum of the vector meson and is a function of q^2, and the factor η=+1 ($\eta = -1$) applies to B (D) decays. The angles θ_ℓ, θ_V, and χ are defined in Fig. 1. The helicity amplitudes $H_\pm$ and H_0 can be expressed in terms of two axial-vector form factors, $A_1(q^2)$ and $A_2(q^2)$, and a vector form factor $V(q^2)$:

$$\begin{aligned} H_\pm(q^2) =& (M+m) A_1(q^2) \mp \frac{2M\, k_V}{(M+m)} V(q^2) \\ H_0(q^2) =& \frac{1}{2m\sqrt{q^2}} \left[(M^2 - m^2 - q^2)(M+m) A_1(q^2) - \frac{4M^2 k_V^2}{(M+m)} A_2(q^2) \right] , \end{aligned} \tag{3}$$

where m is the mass of the daughter meson. The form factors f_+, A_1, A_2, and V are dimensionless.

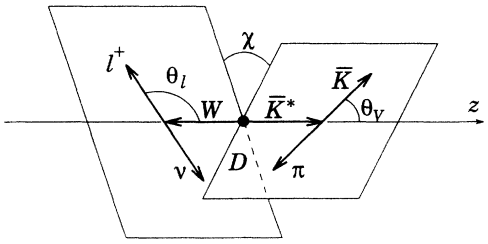

Figure 1: Definition of the angles θ_ℓ, θ_V, and χ. The decay $D \to \overline{K}^* \ell^+ \nu_\ell$ is used as an example. The polar angles θ_ℓ and θ_V are defined in the rest frames of the virtual W and the $\overline{K}^*$, respectively, and χ is the azimuthal angle between the projections of the lepton and the kaon momentum vectors in the plane perpendicular to z.

The $V-A$ coupling results in a larger amplitude to produce a negative-helicity vector meson in $c\overline{q}$ or $b\overline{q}$ decay than one of positive helicity: $|H_-| > |H_+|$. This difference produces a forward-backward asymmetry for the charged lepton in the virtual-W rest frame, since the net angular momentum along the decay axis of the initial heavy meson must be zero. For $D(c\overline{q})$ decays, a positively charged (right-handed) lepton is produced in association with a left-handed daughter s or d quark, resulting in a softer energy spectrum for the charged lepton than for the neutrino after boosting the lepton energy into the D rest frame. (A similar argument shows that the shape of the spectrum is the same for a $\overline{D}$ decay.) For $\overline{B}(b\overline{q})$ decays, a negatively charged (left-handed) lepton is produced in association with a left-handed daughter quark, giving a harder energy spectrum for the charged lepton than for the neutrino in the B rest frame. In $P \to P' \ell \nu_\ell$ decays, there is no asymmetry, since the P' meson can only have helicity zero. Thus, the effect of $V-A$ is to soften the inclusive lepton spectrum in D decays and to harden it in B decays. It is useful to define rates for decays into specific helicity states:

$$\Gamma_i = \frac{G_F^2 |V_{q'Q}|^2}{96\pi^3} \int dq^2\, k_V \frac{q^2}{M^2} |H_i(q^2)|^2 \ . \tag{4}$$

Experiments extract various ratios of these rates, including Γ_+/Γ_-, $\Gamma_L/\Gamma_T = \Gamma_0/(\Gamma_- + \Gamma_+)$, the lepton forward-backward asymmetry $A_{FB} = (3\eta/4)(\Gamma_- - \Gamma_+)/\Gamma$, and the polarization parameter $\alpha = 2\Gamma_0/(\Gamma_+ + \Gamma_-) - 1$. The three form factors can be obtained by fitting the measured distribution of the variables q^2, θ_ℓ, θ_V, and χ.

III. D-meson semileptonic decays

In this Section, we review the main results on D and D_s semileptonic decays, including measurements of $D \to \overline{K}\ell^+\nu_\ell$ and $D \to \overline{K}^*\ell^+\nu_\ell$ form factors. An important question is whether the sum of the exclusive rates for these two modes, plus the corresponding Cabibbo-suppressed rates, saturate the inclusive rate. This issue can also be addressed by searching for Cabibbo-favored semileptonic decays to hadronic systems other than the K or K^*, referred to here as nonresonant states. It is also of great interest to measure the Cabibbo-suppressed semileptonic decays of the D^0 and D^+ and the semileptonic decays of the D_s^+. These decays differ from the dominant K or K^* decays by the strange quark content of either the initial meson or the final meson, or both. Although there are differences in the q^2 ranges and the pole masses for Cabibbo-favored and Cabibbo-suppressed decays, the form-factor intercepts for these modes should be similar. We review the measurements that attempt to address these questions. In our tables, averages of experimental results labeled "*PDG value*" are not necessarily an exact average of the numbers in the tables but come from making an overall fit to the branching ratios in the Full Listings that follow this Note.

$D \to \overline{K}\ell^+\nu_\ell$ decays

With the new CLEO-II measurement [4], the ratio $\Gamma(D^0 \to K^-e^+\nu_e)/\Gamma(D^0 \to K^-\pi^+)$ is one of the most accurately determined quantities in charm physics. This measurement, together with the new, more precise value of the absolute $D^0 \to K^-\pi^+$ branching fraction, yields a much improved measurement of $B(D^0 \to K^-e^+\nu_e)$, as shown in Table 1. Note that e–μ universality is assumed, and that muon measurements have been scaled up by a factor of 1.03 to account for the reduced phase space. Therefore, all results are expressed as electron branching fractions. The transition rate, $\Gamma(D^0 \to K^-e^+\nu_e) = (8.9 \pm 0.5) \times 10^{10}$ s^{-1}, shown in Table 10, is obtained using the PDG branching fraction of Table 1 and the PDG value of the D^0 lifetime.

Table 1: Measurements of the $D^0 \to K^-e^+\nu_e$ branching fraction. The PDG branching fraction for $D^0 \to K^-\pi^+$ has been used, where needed, to normalize.

Isospin symmetry requires equal transition rates for the Cabibbo-favored D^0 and D^+ decays. The D^+ branching fraction measurements are given in Table 2, using our branching fractions for the normalizing modes. The average $D^+ \to \overline{K}^0e^+\nu_e$ transition rate is $(6.3 \pm 0.8) \times 10^{10}$ s^{-1}, significantly lower than $\Gamma(D^0 \to K^-e^+\nu_e)$, although it is less well measured. The discrepancy may be be due, in part, to poorly measured normalizing branching fractions. In any case, we use the average transition rate $\Gamma(D \to \overline{K}e^+\nu_e) = (8.2 \pm 0.4) \times 10^{10}$ s^{-1} to compute the form factor discussed below.

* Average of electrons and muons.

The decay $D^0 \to K^- e^+ \nu_e$ is the only one so far that allows a useful study of the q^2 dependence of heavy-meson form factors. Experiments to date are precise enough to determine only an intercept and a slope parameter for the function $f_+^K(q^2)$. This form factor is commonly parametrized with a pole form,

$$f_+^K(q^2) = f_+^K(0)/(1 - q^2/m_p^2) \ , \tag{5}$$

where m_p is an appropriate pole mass, expected to be approximately the mass of the D_s^*. Values of m_p derived from the experiments are given in Table 1 and are in agreement with $m_{D_s^*}$. The form-factor intercept is computed by integrating Eq. (1), assuming the pole form for $f_+^K(q^2)$. Using the average transition rate of the two charge states, the result is $|f_+^K(0)||V_{cs}| = 0.73 \pm 0.02 \pm 0.02$, where the first error is from the uncertainty in the decay rate and the second is from the uncertainty in the shape of $f_+^K(q^2)$. Using $|V_{cs}| = 0.974$ from the unitarity of the CKM matrix, the value $f_+^K(0) = 0.75 \pm 0.02 \pm 0.02$ is obtained. This result is in general agreement with predictions from models and lattice gauge calculations, as shown in Table 8.

$D \to \overline{K}^* \ell^+ \nu_\ell$ decays

The differential decay distribution for $D \to \overline{K}^* \ell^+ \nu_\ell$ is governed, as explained in Section II, by one vector and two axial-vector form factors. Experiments do not yet have enough data to measure the q^2 dependences of these form factors. The practice is to assume that they have a simple pole form, as for the pseudoscalar case, using for pole masses those of the lowest lying $c\bar{s}$ states with the appropriate quantum numbers: the D_s^* mass, 2.1 GeV, for the pole mass m_V, and the D_s^{**} mass, 2.5 GeV, for m_A. The ratios of form-factor intercepts, $R_2 = A_2(0)/A_1(0)$ and $R_V = V(0)/A_1(0)$, are then determined by fitting to the q^2 and angular decay distributions. These ratios have been measured in $D^+ \to \overline{K}^{*0} \ell^+ \nu_\ell$ decay and are given in Table 3. The corresponding ratios of longitudinal to transverse polarization, and of positive to negative transverse polarization, are also shown.

Table 3: $D^+ \to \overline{K}^{*0} \ell^+ \nu_\ell$ form factor ratios.

The normalization of the form factors is given by the transition rate, which is proportional to $A_1(0)^2$ and is only weakly dependent on R_V and R_2. Tables 4 and 5 give measurements of the $D^+ \to \overline{K}^{*0} e^+ \nu_e$ and $D^0 \to K^{*-} e^+ \nu_e$ branching fractions with the associated average transition rates in Table 10. The D^+ measurement is the better of the two, due to the long D^+ lifetime, the high efficiency for observing the $\overline{K}^{*0}$, and the recent, more precise measurement of the normalizing $D^+ \to K^- \pi^+ \pi^+$ branching fraction.

The new measurements confirm the old result that the transition rates for K^* decays are significantly smaller than for K decays, contrary to expectations from models. This result is also confirmed by several direct measurements of the K^*-to-K ratio, obtained without the use of normalizing branching fractions, shown in Table 6. This ratio is about 0.6, which leads to the low values for the form-factor intercepts $A_1(0)$ and $A_2(0)$ given in Table 7. These values are compared with predictions in Table 8. Note that the form-factor intercepts in these tables have been corrected for the new average value $\Gamma(D \to \overline{K}^* e^+\nu_e) = (4.6 \pm 0.4) \times 10^{10}\ s^{-1}$.

Cabibbo-suppressed semileptonic decays

The rates of Cabibbo-suppressed pseudoscalar semileptonic decays determine the product of $|V_{cd}|$ times a form factor. Assuming that $|V_{cd}|$ is known precisely from unitarity of the CKM matrix, the main goal is to determine the form factor. The form factors measured in Cabibbo-suppressed charm decays are related by HQET [38] to those for $b \to u$ semileptonic decays in the q^2 region near $q^2_{\rm max}$, approximately 18–26 GeV^2. Assuming appropriate pole forms for the form factors, the ratios of branching fractions can be written as

$$R_\pi = \frac{\mathrm{B}(D^0 \to \pi^- e^+\nu_e)}{\mathrm{B}(D^0 \to K^- e^+\nu_e)} = 2 \times \frac{\mathrm{B}(D^+ \to \pi^0 e^+\nu_e)}{\mathrm{B}(D^+ \to \overline{K}^0 e^+\nu_e)} = 1.97 \times \left|\frac{f_+^\pi(0)}{f_+^K(0)}\right|^2 \left|\frac{V_{cd}}{V_{cs}}\right|^2 . \quad (6)$$

The factor of 2 difference between these two modes arises from the $1/\sqrt{2}$ in the coupling of $d\bar{d}$ to a π^0.

To date, measurements of Cabibbo-suppressed semileptonic decays suffer from poor statistics; better results should be forthcoming from the new high-statistics charm experiments. The MARK-III measurement [20] of $\mathrm{B}(D^0 \to \pi^- e^+\nu_e)$, together with our value

for $B(D^0 \to K^- e^+ \nu_e)$ from Table 1, yields $R_\pi = 0.11^{+0.06}_{-0.03} \pm 0.1$. This can be compared with the CLEO-II measurement of $B(D^+ \to \pi^0 e^+ \nu_e)$ [21], giving $R_\pi = 0.17 \pm 0.05 \pm 0.03$. From unitarity of the CKM matrix, we have $|V_{cd}/V_{cs}|^2 = 0.051 \pm 0.002$, giving values of $|f_+^\pi(0)/f_+^K(0)| = 1.0^{+0.3}_{-0.2} \pm 0.04$ and $1.3 \pm 0.2 \pm 0.1$ for the MARK-III and CLEO-II results. Model predictions, which range from 0.7 to 1.4 [39], are in agreement with these results. The E653 collaboration [22] reports a measurement, $\Gamma(D^+ \to \rho^0 \mu^+ \nu_\mu)/\Gamma(D^+ \to \overline{K}^{*0} \mu^+ \nu_\mu) = 0.044^{+0.031}_{-0.025} \pm 0.014$, in good agreement with expectations, within the large errors.

Nonresonant semileptonic decays

There is now substantial evidence that Cabibbo-favored semileptonic decays are nearly saturated by $D \to \overline{K} e^+ \nu_e$ and $D \to \overline{K}^* e^+ \nu_e$. Table 9 gives the results of searches for other decays. Early results from the hybrid bubble chamber [37] indicating large nonresonant contributions are clearly inconsistent with much more sensitive later measurements. Limits on the sum of the nonresonant (and higher-mass resonant) decays can be inferred from the comparison of the sum of exclusive rates with the inclusive rate, as discussed below.

Table 9: Limits on specific nonresonant modes.

Experiment	Reference	Mode	$\Gamma/10^{10}$ s^{-1} 90% CL upper limit
E687	[16] FRABETTI 93E	$D^+ \to (K^-\pi^+)_{\rm NR}\mu^+\nu_\mu$	< 0.4
		$D^+ \to K^-\pi^+\pi^0\mu^+\nu_\mu$	< 0.1
E653	[17] KODAMA 93B	$D^0 \to K^-\pi^+\pi^-\mu^+\nu_\mu$	< 0.3
		$D^0 \to (K^*\pi)^-\mu^+\nu_\mu$	< 0.4

Inclusive semileptonic decays

The inclusive transition rates are $\Gamma(D^+ \to X e^+ \nu_e) = (16.3 \pm 1.8) \times 10^{10}$ s^{-1} and $\Gamma(D^0 \to X e^+ \nu_e) = (18.6 \pm 2.9) \times 10^{10}$ s^{-1}. These rates are dominated by old MARK-III measurements [23]. Isospin symmetry requires that the Cabibbo-favored semileptonic rates for the two charged states be equal, but small differences can be expected for the Cabibbo-suppressed rates. We ignore these differences, which are expected to be less than 2% of the inclusive rate, and use the average for the two charge states, $\Gamma(D \to X e^+ \nu_e) = (16.9 \pm 1.5) \times 10^{10}$ s^{-1}. This inclusive rate can be compared with the sum of the rates for $D \to \overline{K} e^+ \nu_e$, $D \to \overline{K}^* e^+ \nu_e$, and an estimated 8% contribution for the Cabibbo-suppressed modes, as shown in Table 10. (We average the D^0 and D^+ exclusive rates here as well.) The sum of these rates implies a deficit of slightly less than two standard deviations. CLEO [4] has measured all four of the exclusive K and K^* modes, normalizing to the best measured decay, $D^0 \to K^-\pi^+$. Averaging over the charge states, CLEO obtains $\Gamma(D \to (\overline{K} + \overline{K}^*) e^+ \nu_e) = (14.8 \pm 1.3) \times 10^{10}$ s^{-1}. Adding 8% for Cabibbo-suppressed decays results in a deficit of $(0.9 \pm 2.0) \times 10^{10}$ s^{-1}, consistent with zero. The rather large errors leave some room for small contributions from other exclusive channels. As seen in Table 9, the limits on individual channels are much more stringent.

Table 10: Exclusive transition rates. For comparison, $\Gamma(D \to X e^+ \nu_e) = (16.9 \pm 1.5) \times 10^{10}$ s^{-1}.

Mode	$\Gamma(D^0)/10^{10}$ s^{-1}	$\Gamma(D^+)/10^{10}$ s^{-1}	$\Gamma_{\rm Ave}/10^{10}$ s^{-1}
$D \to \overline{K} e \nu_e$	8.9 ± 0.5	6.3 ± 0.8	8.2 ± 0.4
$D \to \overline{K}^* e \nu_e$	4.8 ± 1.0	4.5 ± 0.4	4.6 ± 0.4
Estimated Cabibbo-suppressed			1.0 ± 0.3
Sum of exclusive rates			13.8 ± 0.6

D_s^+ semileptonic decays

Because ϕ mesons are easy to observe, the first D_s^+ semileptonic decay measured was the decay to a vector, $D_s^+ \to \phi \ell^+ \nu_\ell$. The ratio of decay rates, $R_\phi \equiv \Gamma(D_s^+ \to \phi \ell^+ \nu_\ell)/\Gamma(D_s^+ \to \phi \pi^+)$, has been measured by several experiments (Table 11). The average value given in the table includes both electron and muon results.

Table 11: Measurements of $R_\phi \equiv \Gamma(D_s^+ \to \phi \ell^+ \nu_\ell)/\Gamma(D_s^+ \to \phi \pi^+)$.

Experiment	Reference	R_ϕ
CLEO-I	[28] ALEXANDER 90B	$0.49 \pm 0.10^{+0.10}_{-0.14}$
ARGUS	[27] ALBRECHT 91	$0.57 \pm 0.15 \pm 0.15$
E687	[26] FRABETTI 93G	$0.58 \pm 0.17 \pm 0.07$
CLEO-II	[25] BUTLER 94	$0.54 \pm 0.05 \pm 0.04$
PDG value		0.54 ± 0.05

As yet there are no direct measurements of D_s^+ branching fractions. One method for estimating the $D_s^+ \to \phi\pi^+$ branching fraction is based on the belief that $D_s^+ \to \phi\ell^+\nu_\ell$ and $D \to \overline{K}^*\ell^+\nu_\ell$ decays are quite similar. Quark-model-based estimates [40] for the ratio $\kappa = \Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D \to \overline{K}^*\ell^+\nu_\ell)$ are about 1.0. The branching fraction is then

$$\mathrm{B}(D_s^+ \to \phi\pi^+) = \frac{\tau_{D_s}\,\kappa\,\Gamma(D \to \overline{K}^*\ell^+\nu_\ell)}{R_\phi}\,. \tag{7}$$

The average over the two $\Gamma(D \to \overline{K}^*e^+\nu_e)$ charge states is $(4.6 \pm 0.4) \times 10^{10}$ s^{-1}. Using the PDG value for the D_s^+ lifetime, the value for R_ϕ in Table 11, and $\kappa = 1.0$ gives $\mathrm{B}(D_s^+ \to \phi\pi^+) = (4.0 \pm 0.5)\%$. This value also has a theoretical uncertainty, which we conservatively estimate to be about 25%. (The PDG value of this branching fraction, which combines several estimates, is (3.5±0.4)%.)

We will have more confidence in this method for determining the absolute D_s^+ branching fraction scale, and indeed more confidence in our understanding of charmed semileptonic decays in general, if the patterns for the D_s^+ semileptonic decays are seen to be the same as those for D^0 and D^+. It is important to measure the form factor ratios for $D_s^+ \to \phi\ell^+\nu_\ell$ decay, as has been done for $D \to \overline{K}^*\ell^+\nu_\ell$, to shed some light on the validity of the assumption of equal transition rates. With small numbers of events, Fermilab experiments E653 and E687 have made first measurements of these ratios (Table 12). These results, to be compared with the $D \to \overline{K}^*e\nu_e$ values of Table 3, are not yet precise enough to draw conclusions about the degree of similarity of the D_s^+ and D decays.

Perhaps even more important is the ratio of the rates of semileptonic decays of the D_s^+ to vector and pseudoscalar mesons, since this ratio is not as expected in D^+ and D^0 decays. The first observation of the pseudoscalar modes is from Fermilab E653 [24], who obtained $[\Gamma(D_s^+ \to \phi\mu^+\nu_\mu)]/[\Gamma(D_s^+ \to (\eta+\eta')\mu^+\nu_\mu)] = 0.26 \pm 0.11$. The result is certainly consistent with a low vector-to-pseudoscalar ratio. This experiment was unable to separate the η and η' modes.

Table 12: $D_s^+ \to \phi\ell^+\nu_\ell$ form factor ratios.

Experiment	Ref.	$R_2(0)$	$R_V(0)$	Γ_L/Γ_T
E653	[24]	$2.1^{+0.6}_{-0.5} \pm 0.2$	$2.3^{+1.1}_{-0.9} \pm 0.4$	$0.54 \pm 0.21 \pm 0.10$
E687	[29]	$1.1 \pm 0.8 \pm 0.1$	$1.8 \pm 0.9 \pm 0.2$	$1.0 \pm 0.5 \pm 0.1$
Ave.		1.8 ± 0.5	2.0 ± 0.7	0.6 ± 0.2

Conclusions on D-meson semileptonic decays

The study of semileptonic decays of D mesons has progressed enormously in the last few years. The q^2 dependence of the pseudoscalar form factor has been measured, and the intercepts of the three vector-decay form factors been determined by several experiments. New experiments confirm the old observation that the $D \to \overline{K}^*\ell^+\nu_\ell$ decay rate, and therefore the A_1 form factor, is low compared with model calculations. Presently, no model appears able to explain all of the form factors.

Problems remain in the precise quantitive comparisons between the transition rates of the different charge states in the $D \to \overline{K}\ell^+\nu_\ell$ exclusive decays. The difficulty may lie in the branching fractions of the normalizing modes for the D^+ decays. Strict upper limits are observed on rates of nonresonant decays. These limits are consistent with the observation that the transition rates for $D \to \overline{K}\ell^+\nu_\ell$ and $D \to \overline{K}^*\ell^+\nu_\ell$, plus a reasonable estimate of the Cabibbo-suppressed rate, nearly saturates the inclusive rate.

Measurements of Cabibbo-suppressed semileptonic decays have begun. Experiments are making good progress with D_s^+ semileptonic decays. First results have been obtained for the ratios of form-factor intercepts in $D_s^+ \to \phi\ell^+\nu_\ell$ and for observations of the pseudoscalar decays $D_s^+ \to \eta\ell^+\nu_\ell$ and $D_s^+ \to \eta'\ell^+\nu_\ell$.

In the near future, we can expect further significant advances. It will be very interesting to compare the form factors for Cabibbo-favored, Cabibbo-suppressed, and D_s^+ decays for the pseudoscalar- and vector-meson final states. Measurement of the q^2 dependences of the three vector-decay form factors may help in understanding the puzzle of the small semileptonic transition rate to vector-meson final states.

Continuation of this discussion can be found in the Listings for the $B^\pm$.

Γ_{145} A dummy mode used by the fit. (34 ±5) %

[a] This is a weighted average of $D^{\pm}$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \rightarrow$ (ηanything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Full Listings.

[b] This value combines the e^+ and μ^+ branching fractions, making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence the "e^+." In fact, some of the e^+ measurements already use μ^+ events in this way.

[c] ℓ indicates e or μ mode, not sum over modes.

[d] The branching fractions for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[e] The two experiments determining this ratio are in serious disagreement. See the Full Listings.

[f] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[g] The value is for the sum of the charge states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 26 branching ratios uses 45 measurements and one constraint to determine 17 parameters. The overall fit has a $\chi^2 = 14.5$ for 29 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$0.243^{+0.064}_{-0.041}\pm0.041$	11	[44] AGUILAR-...	87F	HYBR	πp, pp 360, 400 GeV

[43] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.51 ± 0.08. We use the MARK-3 (ADLER 88C) value of $\sigma = 4.2 \pm 0.6 \pm 0.3$ nb.

[44] AGUILAR-BENITEZ 87F and BARLAG 92C compute the branching fraction by topological normalization.

$D^{\pm}$ PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of $D^{\pm}$ mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
4.2 ±0.6 ±0.3	[67] ADLER 88C	MRK3	e^+e^- 3.768 GeV
5.5 ±1.0	[68] PARTRIDGE 84	CBAL	e^+e^- 3.771 GeV
6.00±0.72±1.02	[69] SCHINDLER 80	MRK2	e^+e^- 3.771 GeV
9.1 ±2.0	[70] PERUZZI 77	MRK1	e^+e^- 3.774 GeV

[67] This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C measure the ratio of cross sections (neutral to charged) to be 1.36 ± 0.23 ± 0.14. This measurement does not include the decays of the $\psi(3770)$ not associated with charmed particle production.

[68] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[69] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[70] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

[1] PERUZZI 77 and SCHINDLER 81 errors do not include the 0.13% uncertainty in the absolute SPEAR energy calibration. TRILLING 81 uses the high precision $J/\psi(1S)$ and $\psi(2S)$ measurements of ZHOLENTZ 80 to determine this uncertainty and combines the PERUZZI 77 and SCHINDLER 81 results to obtain the value quoted. TRILLING 81 enters the fit in the $D^{\pm}$ mass, and PERUZZI 77 and SCHINDLER 81 enter in the $m_{D^{\pm}} - m_{D^0}$, below.

[2] Error does not include possible systematic mass scale shift, estimated to be less than 5 MeV.

$|m_{D_1^0} - m_{D_2^0}|$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson.

[3] Limit inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-(\text{via }\overline{D}^0))/\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[4] Calculated by us using $\Delta(m) = (2r/(1-r))^{1/2}\hbar/4.21 \times 10^{-13}$ s, where r is the D^0-$\overline{D}^0$ mixing ratio. See the data on $r \equiv \Gamma(K^+\pi^-(\text{via }\overline{D}^0))/\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[5] Limit inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(\mu^-\text{anything (via }\overline{D}^0))/\Gamma(\mu^+\text{anything})$ near the end of the D^0 Listings.

[6] YAMAMOTO 85 gives $\Delta(m)/\Gamma < 0.44$. We use $\Gamma = \hbar/4.3 \times 10^{-13}$ s.

$m_{D^{\pm}} - m_{D^0}$

The fit includes $D^{\pm}$, D^0, $D_s^{\pm}$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements.

[9] This limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-(\text{via }\overline{D}^0))/\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[10] Calculated by us using $\Delta\Gamma = (8r/(1+r))^{1/2}\hbar/4.21 \times 10^{-13}$ s, where r is the D^0-$\overline{D}^0$ mixing ratio. See the data on $r \equiv \Gamma(K^+\pi^-(\text{via }\overline{D}^0))/\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[11] Limit inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(\mu^-\text{anything (via }\overline{D}^0))/\Gamma(\mu^+\text{anything})$ near the end of the D^0 Listings.

D^0 DECAY MODES

$\overline{D}^0$ modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
	Inclusive modes			
Γ_1	e^+ anything		(7.7 ± 1.2) %	S=1.1
Γ_2	μ^+ anything		(10.0 ± 2.6) %	
Γ_3	K^- anything		(53 ± 4) %	S=1.3
Γ_4	$\overline{K}^0$ anything + K^0 anything		(42 ± 5) %	
Γ_5	K^+ anything		(3.4 $^{+\ 0.6}_{-\ 0.4}$) %	
Γ_6	η anything	[a]	< 13 %	CL=90%
	Semileptonic modes			
Γ_7	K^- "e^+" ν_e	[b]	(3.68± 0.21) %	S=1.1
Γ_8	$K^- e^+ \nu_e$		(3.80± 0.22) %	S=1.1
Γ_9	$K^- \mu^+ \nu_\mu$		(3.2 ± 0.4) %	
Γ_{10}	$K^-\pi^0 e^+ \nu_e$	[c]	(1.6 $^{+\ 1.3}_{-\ 0.5}$) %	
Γ_{11}	$\overline{K}^0\pi^- e^+ \nu_e$	[c]	(2.8 $^{+\ 1.7}_{-\ 0.9}$) %	
Γ_{12}	$\overline{K}^*(892)^- e^+ \nu_e$ × B($K^{*-} \to \overline{K}^0\pi^-$)		(1.3 ± 0.3) %	
Γ_{13}	$K^*(892)^- \ell^+ \nu_\ell$	[d]		
Γ_{14}	$K^-\pi^0(\pi^0) e^+ \nu_e$			
Γ_{15}	$\overline{K}^0\pi^-(\pi^0) e^+ \nu_e$			
Γ_{16}	$\overline{K}^*(892)^0\pi^- e^+ \nu_e$	[e]	< 1.3 %	CL=90%
Γ_{17}	$K^-\pi^+\pi^-\mu^+\nu_\mu$		< 1.2 × 10^{-3}	CL=90%
Γ_{18}	$(\overline{K}^*(892)\pi)^-\mu^+\nu_\mu$		< 1.4 × 10^{-3}	CL=90%
Γ_{19}	$\pi^- e^+ \nu_e$		(3.9 $^{+\ 2.3}_{-\ 1.2}$) × 10^{-3}	

A fraction of the following resonance mode has already appeared above as a submode of a particular charged-particle mode.

Γ_{20}	$K^*(892)^- e^+ \nu_e$	(2.0 ± 0.4) %

Γ_{154} A dummy mode used by the fit. (24 ± 4) % S=1.1

[a] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0\to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Full Listings.

[b] This value combines the e^+ and μ^+ branching fractions, making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence the "e^+." In fact, some of the e^+ measurements already use μ^+ events in this way.

[c] See the "Note on Semileptonic Decays of D and B Mesons" in the D^+ Full Listings for a comparison of inclusive and summed-inclusive branching fractions.

[d] ℓ indicates e or μ mode, not sum over modes.

[e] The limit on $(\overline{K}^*(892)\pi)^-\ \mu^+\nu_\mu$ just below is much stronger.

[f] The branching fractions for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] The two experiments determining this ratio are in serious disagreement. See the Full Listings.

[h] The value is for the sum of the charge states indicated.

Meson Full Listings

D^0

CONSTRAINED FIT INFORMATION

An overall fit to 47 branching ratios uses 102 measurements and one constraint to determine 26 parameters. The overall fit has a $\chi^2 = 50.6$ for 77 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[24] Radiative corrections increase this AKERIB 93 value to 0.0395 ± 0.0008 ± 0.0017.

[25] ABACHI 88, DECAMP 91J, and AKERIB 93 use $D^*(2010)^+ \to D^0\pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis ($\approx D^{*+}$ direction). The excess number of such π^+'s over background gives the number of $D^*(2010)^+ \to D^0\pi^+$ events, and the fraction with $D^0 \to K^-\pi^+$ gives the $D^0 \to K^-\pi^+$ branching fraction.

[26] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.24 ± 0.02. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[27] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.25 ± 0.05. We use the MARK-3 (ADLER 88C) value of σ = 5.8 ± 0.5 ± 0.6 nb.

[28] AGUILAR-BENITEZ 87F and BARLAG 92C compute the branching fraction using topological normalization.

[90] The branching ratios are normalized to $D^0 \to K^-\pi^+$, $D^+ \to K^-\pi^+\pi^+$, and $D^{*+} \to D^0\pi^+$ using ADLER 88C.

[91] RILES 87 assumes $B(D \to K\pi) = 3.0\%$ and has production model dependency.

D^0 PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of D^0 mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
5.8 ± 0.5 ± 0.6	[92] ADLER	88C	MRK3	e^+e^- 3.768 GeV
7.3 ± 1.3	[93] PARTRIDGE	84	CBAL	e^+e^- 3.771 GeV
8.00 $\pm 0.95 \pm 1.21$	[94] SCHINDLER	80	MRK2	e^+e^- 3.771 GeV
11.5 ± 2.5	[95] PERUZZI	77	MRK1	e^+e^- 3.774 GeV

[92] This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C find the ratio of cross sections (neutral to charged) to be $1.36 \pm 0.23 \pm 0.14$.

[93] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[94] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

[95] This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

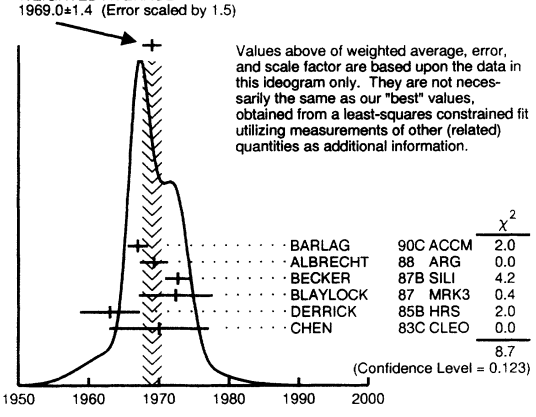
CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$D_s^+ = c\bar{s}$, $D_s^- = \bar{c}s$, similarly for D_s^*'s

$D_s^{\pm}$ was $F^{\pm}$

$I(J^P) = 0(0^-)$



The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

$D_s^{\pm}$ MASS

The fit includes $D^{\pm}$, D^0, $D_s^{\pm}$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the $D_s^{\pm}$ mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements giving $m > 2000$ MeV have been omitted altogether. They may be found in our 1990 edition (Phys. Lett. **B239**).

[2] BARLAG 90C estimates the systematic error to be negligible.
[3] BECKER 87B estimates the systematic error to be negligible.

D_s^+ DECAY MODES

Branching fractions for modes below with a resonance in the final state include all the decay modes of the resonance. D_s^- modes are charge conjugates of the modes below.

Nearly all other modes are measured relative to the $\phi\pi^+$ mode. However, none of the determinations of the $\phi\pi^+$ branching fraction are direct measurements: all rely on calculated relations between D^+ and D_s^+ decay widths, on estimates of D_s^+ cross sections, or on other model-dependent assumptions. Thus a better determination of the $\phi\pi^+$ branching fraction could cause the other branching fractions to slide up or down, all together.

[a] For now, we average together measurements of the $\phi e^+\nu_e$ and $\phi\mu^+\nu_\mu$ branching fractions.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a χ^2 = 9.4 for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_{15}	12			
x_{16}	9	73		
x_{17}	4	32	23	
x_{52}	−32	−87	−87	−55
	x_6	x_{15}	x_{16}	x_{17}

D_s^+ BRANCHING RATIOS

A few older, now obsolete results have been omitted. They may be found in our 1990 edition (Phys. Lett. **B239**).

$0.004\ {}^{+0.0018+0.0020}_{-0.0014-0.0019}$	8	[6] AOKI	93	WA75	π^- emulsion 350 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.03	0	[7] AUBERT	83	SPEC	μ^+ Fe, 250 GeV

[6] AOKI 93 assumes the ratio of production cross sections of the D_s^+ and D^0 is 0.27. The value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{total}$ here gives a pseudoscalar decay constant $f_{D_s} = (232\pm45\pm52)$ MeV.

[7] AUBERT 83 assume that the $D_s^\pm$ production rate is 20% of total charm production rate.

$\Gamma(\mu^+\nu_\mu)/\Gamma(\phi\pi^+)$ Γ_6/Γ_{15}

See the "Note on Pseudoscalar-Meson Decay Constants" in the Listings for the $\pi^\pm$.

[14] BUTLER 94, FRABETTI 93G, ALBRECHT 91, ALEXANDER 90B, and ANJOS 90B measure the ratio $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D_s^+ \to \phi\pi^+)$, where $\ell = e$ and/or μ, and then use a theoretical calculation of the ratio of widths $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D^+ \to \overline{K}^{*0}\ell^+\nu)$. Not everyone uses the same value for this ratio.

[15] The two MUHEIM 94 values here are model-dependent calculations based on distinct data sets. The first uses measurements of the $D_2^*(2460)^0$ and $D_{s1}(2536)^+$, the second uses B-decay factorization and $\Gamma(D_s^+ \to \mu^+\nu_\mu)/\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)$. A third calculation using the semileptonic width of $D_s^+ \to \phi\ell^+\nu_\ell$ is not independent of other results listed here. Note also the upper limit, based on the sum of established D_s^+ branching ratios.

[16] ALVAREZ 90C relies on the Lund model to estimate the ratio of D_s^+ to D^+ cross sections.

[17] Values based on crude estimates of the $D_s^{\pm}$ production level. DERRICK 85B errors are statistical only.

[18] ADLER 90 uses a technique based on full reconstruction of $D_s^+ D_s^-$ pairs (double tags) to obtain a branching ratio limit without assumptions about $\sigma(D_s^{\pm})$.

EXPERIMENTAL HIGHLIGHTS OF B MESON PRODUCTION AND DECAY

(by R.H. Schindler, SLAC)

This edition reflects the impact that CLEO–II has had on beauty, charm, and τ physics in the last two years. Starting in 1991, the CESR storage ring with the new CLEO–II detector ran in the $\Upsilon(4S)$ resonance region collecting record luminosities for a symmetric e^+e^- collider in its first year of $\sim$ 8–9 pb^{-1}/day. Over the past year, the luminosity has risen to $\sim$ 15 pb^{-1}/day and CLEO–II has logged a total of more than 2 fb^{-1}. This edition also contains many new measurements of B mesons and baryons from Z decay, made possible by the addition of high-precision silicon vertex detectors in many of the LEP detectors coupled with their large average accumulations of $\sim$ 750K Z/year since 1992. The implementation of silicon vertexing in CDF at FNAL has made possible the measurement of precise B lifetimes from exclusive decays. The high-energy e^+e^- colliders and detectors (LEP and SLD/SLC) with their silicon-tracking systems are now starting to produce and tag heavy-flavor decays (charm and beauty) of the Z with very high efficiency and purity. This has already resulted in improvements in inclusive and exclusive lifetime measurements, the direct observation of B^0–$\overline{B}^0$ mixing by time evolution, and precision electroweak tests (measurements of the $Zb\overline{b}$ and $Zc\overline{c}$ vertex), both with and without polarized beams.

Perhaps the most exciting result to appear this year is the first observation of radiative "penguin" decays ($b \to s\gamma$ transitions). Extensive sets of branching fraction limits on many exclusive channels in the few parts per 10^4 range were reported previously by CLEO and ARGUS for both hadronic ($b \to sg$) and radiative ($b \to s\gamma$) penguins. In 1993, CLEO–II (AMMAR 93), using about 1.6 fb^{-1} of data, reconstructed eight candidate events in the channel $B^0 \to K^*(892)^0\gamma$ and five in the $B^+ \to K^*(892)^+\gamma$ channel. The $B^0 \to K^*(892)^0\gamma$ branching fraction is about 4×10^{-5} while the $B^+ \to K^*(892)^+\gamma$ branching fraction is 6×10^{-5}. These decays are important because they establish the existence of the penguin diagram, a necessary (but not sufficient) requirement for describing direct CP violation in the Standard Model. The observed branching fractions also set stringent limits on the mass of a charged Higgs scalar in a large class of models, giving $m_{H^+} > 250$ GeV, whereas direct limits from LEP are only about 43 GeV. In the continuing search for hadronic penguins, it appears that CLEO–II is now close to having the sensitivity to observe the simplest two-body channels.

The mixing of B^0 and $\overline{B}^0$ mesons, first suggested by UA1 and subsequently measured by ARGUS, provided the first indirect evidence of a heavy t quark. Mixing of the B^0 has similarly been measured by CLEO with dilepton events at the $\Upsilon(4S)$, and by the LEP experiments at the Z resonance. This year, ALEPH (BUSKULIC 93K) made the first direct measurement of the B^0 mixing by observation of the mixing-oscillation itself over time. This is the forerunner of the measurement of B_s^0 mixing, where present constraints on the CKM matrix suggest that B_s^0 mixing will be found to be nearly maximal ($\chi_s \approx 0.5$). If χ_s is greater than about 0.3–0.4, then greater sensitivity to the CKM parameters ($|V_{tb}V_{ts}^*|$) through B_s mixing will likely come from direct measurement of the mixing-oscillation frequency (the time evolution) rather than from a time-averaged quantity such as χ_s. These studies are only likely to occur in hadron and electron machines where the B mesons are adequately boosted and where pure tagging can be accomplished.

The measured average lifetime of B hadrons has changed dramatically since first measurements at PEP and PETRA. The average value of about 1.29 ± 0.05 ps in our 1992 edition was dominated by LEP measurements using high-statistics impact-parameter techniques with hadrons and leptons. Later LEP measurements average closer to 1.5 ± 0.03 ps. This significant upward drift perhaps reflects improvements in understanding of vertex detectors. The longer average lifetime is confirmed by CDF (ABE 93J). Theory suggests that the inequality of B^+ and B^0 lifetimes may be as small as 5 or 10%, providing an interesting experimental challenge. The separate lifetimes of B^+ and B^0 mesons have been measured indirectly at LEP, looking at the correlation with D^{*+} as an indicator of the B charge. Other techniques have also been applied. The equality of B^+ and B^0 lifetimes is established within about 10% by averaging LEP measurements. Separate B^+ and B^0 lifetimes at this precision will come either from tagging of B mesons at the $\Upsilon(4S)$ with subsequent measurement of the semileptonic decay of the recoil, or from improved statistics for exclusive $B_{\ell 3}$ decays, or from the direct measurement of a decay lifetime of a B^+ or B^0 at LEP/SLC or CDF using vertexing techniques.

Experiments at LEP and CDF at FNAL have isolated B_s^0 and B-baryon decays using ϕ-lepton and Λ-lepton correlations. Explicit examples of decays of the B_s^0 have been reconstructed, and the mass and lifetime have been measured using these events. While the B_s^0 lifetime is similar to those of the B^+ and B^0, the B-baryon lifetime appears to be shorter, perhaps owing to a contribution of exchange diagrams in its decays.

The semileptonic branching fractions are important for establishing the values of the CKM parameters V_{cb} and V_{ub}. The branching fractions to exclusive states $B \to \overline{D}\ell^+\nu_\ell$ and $B \to \overline{D}^*\ell^+\nu_\ell$ have been measured and both CLEO and ARGUS have done form factor decompositions (ALBRECHT 92C, ALBRECHT 93, and SANGHER 93). The inclusive rate for semileptonic decay appears to remain at about $10.0 \pm 0.5\%$. It appears that the sum of $\overline{D}\ell^+\nu_\ell$ and $\overline{D}^*\ell^+\nu_\ell$ contributions accounts for about two-thirds of the inclusive branching fraction. The balance must be a mixture of other channels such as $\overline{D}^{**}\ell^+\nu_\ell$, $\overline{D}\pi\ell^+\nu_\ell$, $\overline{D}^*\pi\ell^+\nu_\ell$ *etc.* Improvements can be anticipated from a comparison of single- and double-tagged

semileptonic decays combined with higher-statistics measurements of the exclusive charged and neutral $B_{\ell 3}$ channels. For more details on semileptonic decays, see the following Note.

In the next few years, CLEO–II and the detectors at high-energy machines at LEP, SLC, HERA, and FNAL should provide new insights into all aspects of B^+, B^0, B_s^0 meson decays. The experimental reach of the present program should be adequate to address all the interesting areas of B physics except CP violation, the study of which requires B factories. follows for a review of the many new results in that area.

NOTE ON SEMILEPTONIC DECAYS OF D AND B MESONS, PART II

(by R.J. Morrison and J.D. Richman, University of California, Santa Barbara)

This is a continuation of the discussion that began in the Listings for the $D^{\pm}$.

IV. B-meson semileptonic decays

In the following sections, we review inclusive and exclusive semileptonic decays of B mesons. A major goal of experiments is to determine the magnitudes of the CKM elements V_{cb} and V_{ub}. There are significant theoretical uncertainties involved in extracting these quantities from the data, and measurements of branching fractions and form factors are part of an ongoing effort to clarify the dynamics of these decays.

The inclusive semileptonic branching fraction

The b-hadron inclusive semileptonic branching fraction, $\mathcal{B}_{SL}$, has been measured both at the $\Upsilon(4S)$, where the b-hadrons are a mixture of B_u and B_d mesons, and at the Z, where B_s-mesons and b-baryons are produced as well. Here $\mathcal{B}_{SL}$ is the branching fraction to either electrons or muons, not their sum. Semileptonic decays to τ leptons are suppressed by phase space and have been observed, within large errors, at the expected level [3,4]. Measurements of $\mathcal{B}_{SL}$ are given in Table 1, for experiments at the $\Upsilon(4S)$, and in Table 2, for the LEP experiments. Table 3 gives the branching fraction for $X_{\overline{b}} \to X\tau^+\nu_\tau$ and certain semi-inclusive modes.

Table 1: Measurements of the inclusive semileptonic branching fraction (%), $\mathcal{B}_{SL}$ = B($B \to X\ell^+\nu_\ell$), averaged over the B mesons produced at the $\Upsilon(4S)$ (B_u and B_d). Results are given separately for each of the models used to extract $\mathcal{B}_{SL}$. In the ARGUS 1ℓ measurement, the first error combines both statistical and systematic uncertainties; the second error in the ACCMM value is due to the extra free parameters present in the ACCMM model. The fit of the CLEO data using the unmodified ISGW model is poor, so the results from that fit are less reliable. The table also gives the CLEO inclusive branching fraction to charm final states ($X_{\overline{c}}$) only, which is extracted from the same fit. (Sources of error in these measurements are discussed in the text.)

Measurement	ACCMM	ISGW	ISGW**
ARGUS 1ℓ [5]	$10.2 \pm 0.5 \pm 0.2$	9.8 ± 0.5

Table 3: Measurements of branching fractions for $X_{\overline{b}} \to X\tau^+\nu_\tau$ and other semi-inclusive modes. B semileptonic decays to final states with baryons have not been observed. The ARGUS result for $B \to D_s{}^- X\ell^+\nu_\ell$ has been rescaled using the PDG value for $D_s^+ \to \phi\pi^+$.

Mode	Expt.	Ref.	B(%)
$X_{\overline{b}} \to X\tau^+\nu_\tau$	ALEPH	[3]	$4.08 \pm 0.76 \pm 0.62$
$X_{\overline{b}} \to X\tau^+\nu_\tau$	ALEPH (prelim.)	[4]	$2.76 \pm 0.47 \pm 0.43$
$B \to D_s{}^- X\ell^+\nu_\ell$	ARGUS	[20]	< 0.9 (90% CL)
$B \to \overline{p}X\ell^+\nu_\ell$	ARGUS	[5]	< 0.16 (90% CL)

The challenge for inclusive measurements is to determine what part of the observed lepton momentum spectrum is due to leptons from b-hadron decay (primary leptons) and what part is due to leptons from charm decay (secondary leptons) or to other sources (misidentified hadrons, photon conversions, $J/\psi(1S)$ decays, *etc.*). The standard technique is to fit the observed lepton momentum spectrum to a sum of the shapes expected for primary and secondary decays, after subtracting out backgrounds from other sources. Thus, a large part of the effort (and uncertainty) in the analysis is in the determination of these shapes.

Experiments at the $\Upsilon(4S)$ (ARGUS and CLEO) use theoretical models to describe the primary lepton spectrum. Some of these models have free parameters that are determined from the fit. The ACCMM model [12], for example, is based on an inclusive calculation of b-quark decay, and it has parameters corresponding to the c-quark mass and the Fermi momentum of the spectator quark, among others. A commonly used exclusive model is ISGW [13], in which the dominant contributions to the primary spectrum are from $B \to \overline{D}\ell^+\nu_\ell$ and $B \to \overline{D}^*\ell^+\nu_\ell$, with some $B \to \overline{D}^{**}\ell^+\nu_\ell$. Here, D^{**} refers to a mixture of p-wave and radially excited charm mesons. CLEO finds [9,10] that the amount of $B \to \overline{D}^{**}\ell^+\nu_\ell$ in this model is too low to adequately describe the lepton momentum spectrum, so a modified version of the ISGW model, ISGW**, has been created. In ISGW**, the D^{**} fraction is allowed to vary, but the D^*-to-D ratio is fixed at the value (2.3) predicted by ISGW. The fit to the CLEO data using ISGW** is significantly better than that using ISGW.

The shape used to describe the secondary lepton spectrum in these fits, although somewhat more complicated to obtain, is based on data. The DELCO charm-decay lepton spectrum [14] is fit to a theoretical model (ACCMM) and then boosted according to the inclusive D-meson momentum spectrum measured at the $\Upsilon(4S)$. Future measurements should be able to use a charm lepton spectrum obtained by summing the spectra for the known exclusive charm semileptonic modes, which account for most of the inclusive rate.

LEP experiments (ALEPH, DELPHI, L3, and OPAL) measure $\mathcal{B}_{SL}$ by fitting the spectra of p and p_T (the momentum transverse to the jet axis) in single lepton and dilepton events. The shape of the primary spectrum is taken from CLEO or ARGUS, so that model-related uncertainties in these experiments are propagated into the LEP results. (This uncertainty is part of the third error in the LEP results given in Table 2. Its size depends on the specific details of the analysis.)

The extraction of the B semileptonic branching fraction from the momentum spectrum of single leptons, therefore, relies on models. In CLEO, which currently has the largest data sample, the spread of values obtained using different models is comparable to the experimental errors. The dominant experimental errors are due to tracking and lepton identification uncertainties, which are expected to decrease in the future.

The ARGUS collaboration [6] has introduced a second method, using dilepton events, that substantially reduces the need for models. One lepton (the "tagging lepton") is required to have high momentum and is thus nearly always primary. The analysis then examines the momentum spectrum of the second lepton in the event. By requiring that both leptons be in the same hemisphere, events in which the two leptons come from the decay chain of a single B meson (produced nearly at rest at the $\Upsilon(4S)$) are effectively removed. Thus, (1) the tagging lepton is primary, and (2) the leptons are from different B mesons. Then, unless mixing occurs, a lepton whose charge is opposite to that of the tagging lepton must be primary, while one with the same charge as the tagging lepton must be secondary. One corrects for mixing by using the known mixing probability. The relative charges of the two leptons, therefore, can be used to separate the primary and secondary spectra of the second lepton. There is a lower momentum cutoff due to experimental acceptance, however, and a small extrapolation, based on models, is required to obtain the total semileptonic rate. The results of this measurement are in agreement with the single-lepton value, although with a poorer statistical error. This method also very much reduces the sensitivity to any possible non-$B\overline{B}$ decays of the $\Upsilon(4S)$, which are assumed to be negligible in the single-lepton method.

The values of $\mathcal{B}_{SL}$ given in Table 1 and Table 2 are lower than theoretical predictions, which give [15] $\mathcal{B}_{SL} \geq 12.5\%$. Such calculations, however, are difficult partly because they must determine the total hadronic rate, which has uncertainties associated with both perturbative and nonperturbative QCD effects. The source of the discrepancy between theory and experiment is not yet understood.

The semileptonic branching fraction can be used to calculate $|V_{cb}|$. The fraction is converted into a decay rate using the measured B lifetime, and the rate is then compared with model predictions, which depend on $|V_{cb}|^2$. Whereas the model dependence in the determination of $\mathcal{B}_{SL}$ is associated with the predicted shapes of momentum spectra, the extraction of $|V_{cb}|$ is also sensitive to the uncertainty in the normalization of the predicted rate. It is difficult to assign errors to rate predictions based on quark-model calculations. Quite often, a nominal theoretical error of 20% in the rate is assumed, leading to a 10% theoretical error on $|V_{cb}|$. This uncertainty is separate from the model dependence, if any, in extracting the branching fraction. The CLEO-II preliminary results (assuming the value [16] $\tau_B = 1.49 \pm 0.04$ ps which is used in Sec. 28 "The Cabibbo-Kobayashi-Maskawa Mixing Matrix") for $B \to X_{\bar{c}}\ell^+\nu_\ell$ in Table 1 give [17]

$$|V_{cb}| = (0.042 \pm 0.001 \pm 0.004)\sqrt{\frac{1.49}{\tau_B(\text{ps})}} \qquad (1)$$

for both ACCMM and ISGW**. (The value for V_{cb} in Sec. 28 "The Cabibbo-Kobayashi-Maskawa Mixing Matrix" is not based on this measurement but on the $B \to \overline{D}^*\ell^+\nu_\ell$ rate at zero D^* recoil velocity.)

Currently, there is interest in using the methods of HQET to obtain a value of $|V_{cb}|$ from the inclusive spectrum with a better understood error. Luke and Savage [18] use the inclusive branching fraction to obtain the range $0.038 < |V_{cb}| < 0.054$, where we have corrected their result to $\tau_B = 1.49$ ps. Shifman, Uraltsev, and Vainshtein [19] argue that the present theoretical uncertainty on $|V_{cb}|$ may be as low as 5% and can be made even lower. We discuss the determination of $|V_{cb}|$ using exclusive processes in Section IV.4.

Table 3 lists additional inclusive B branching fractions that involve leptons. The decay $X_{\bar{b}} \to X\tau^+\nu_\tau$ has been difficult to observe, due to the presence of two neutrinos. However, ALEPH has used decay configurations with a large missing energy in the b-hadron rest frame. In Z decays, the boost of the b hadron to the lab frame can result in a very large missing energy (10–30 GeV) for the hemisphere containing the decay. By looking for events with both a large missing energy and a tagged b hadron (using vertex detector information), ALEPH has been able to measure $\mathrm{B}(X_{\bar{b}} \to X\tau^+\nu_\tau)$ with a value consistent with standard model expectations. (The preliminary ALEPH result in Table 3 includes data from the original measurement, so the two results cannot be averaged.)

The lepton endpoint region and the determination of $|V_{ub}|$

The determination of $|V_{ub}|$ is one of the most important and challenging measurements in B physics. For $|V_{ub}/V_{cb}| \approx 0.1$, the rate for $B \to X_{\bar{u}}\ell^+\nu_\ell$, where $X_{\bar{u}}$ is a charmless hadronic system, is expected to be only about 1% of the inclusive semileptonic rate. By working in the region at and beyond the lepton-momentum-spectrum endpoint for $B \to X_{\bar{c}}\ell^+\nu_\ell$ processes, however, one gains enormously in sensitivity to $B \to X_{\bar{u}}\ell^+\nu_\ell$ decays.

Although the advantages of working in this endpoint region ($2.3 < p_\ell < 2.6$ GeV/c) are decisive, there are also disadvantages. A major difficulty is the need to convert the measured rate for this tiny portion of phase space into a value of $|V_{ub}|$. This calculation can be performed using either inclusive or exclusive models, but both have substantial uncertainties in predicting the rate in the endpoint region. Inclusive models are expected to be fairly reliable, if one considers a large enough part of phase space, but they may not be reliable in the endpoint region, which some theorists argue [13] is dominated by a small set of exclusive channels ($B \to \rho\ell^+\nu_\ell$, $B^+ \to \omega\ell^+\nu_\ell$, and $B \to \pi\ell^+\nu_\ell$). Alternatively, exclusive models can be used to predict the sum of contributions of individual modes in this region. However, large uncertainties exist in the calculations of the rates for exclusive modes, and some of the observed rate may be due to nonresonant final states [24]. The exclusive calculations here are more difficult than those for $B \to X_{\bar{c}}\ell^+\nu_\ell$, because the range of recoil velocities available to the light final-state mesons in a $B \to X_{\bar{u}}\ell^+\nu_\ell$ transition is much larger than for the charm mesons in a $B \to X_{\bar{c}}\ell^+\nu_\ell$ decay. One therefore expects a much larger variation in the (poorly known) form factors that enter into the decay rate. As a result, measurements of $|V_{ub}|$ are currently quite model dependent, and there is substantial variation among values obtained using different models.

The analysis of the endpoint region, although an "inclusive" measurement, is quite different from the measurement of $\mathcal{B}_{SL}$ described in the previous section: at the $\Upsilon(4S)$, nonresonant (continuum) processes produce high-momentum leptons that constitute an enormous background (relative to a $B \to X_{\bar{u}}\ell^+\nu_\ell$ signal) unless suppressed by kinematic cuts. The signal efficiency of these cuts is model dependent, unlike the very loose cuts used in the analysis of the inclusive lepton spectrum. In particular, the efficiency depends on the q^2 distribution of the signal events, so the value obtained for the rate in the endpoint region depends on the shape assumed for this distribution. The most important sensitivity to models, however, arises when one converts the rate to $|V_{ub}|$.

Table 4 lists the measurements of $|V_{ub}/V_{cb}|$ from CLEO and ARGUS. The CLEO-II studies, which are based on about five times as much data as either the original ARGUS or the CLEO-I analyses, yield values of $|V_{ub}/V_{cb}|$ significantly lower than the earlier measurements.

Table 4: Measurements of $|V_{ub}/V_{cb}|$ using the inclusive rate in the endpoint region. The ARGUS and CLEO-I results are each based on about 200,000 $b\bar{b}$ events, and the CLEO-II results are based on about 955,000 $b\bar{b}$ events.

Model	ARGUS [21]	CLEO-I [22]	CLEO-II [23]
ACCMM	0.11 ± 0.012	0.09 ± 0.01	0.076 ± 0.008
ISGW	0.20 ± 0.023	0.15 ± 0.02	0.101 ± 0.010

Exclusive semileptonic decays

Measurements of exclusive semileptonic decays of B mesons are less precise and less complete than those for D mesons. Table 5 lists the branching fractions, which assume that the branching fractions of the $\Upsilon(4S)$ to B^+B^- and $B^0\overline{B}^0$ are given by $f_{+-} = f_{00} = 0.5$. Two techniques have been used to study $B \to \overline{D}^* \ell^+ \nu_\ell$, the only well-measured decay mode. In the first, used by both CLEO and ARGUS, the D^* and D mesons are fully reconstructed. Signal events produce a narrow peak in the $D^* - D$ mass difference distribution, as well as a peak near zero, indicating a neutrino, in the distribution of the missing mass recoiling against the $\overline{D}^* \ell^+$ system. This latter peak is broadened by the assumption that the momentum of the B at the $\Upsilon(4S)$ is zero; in reality it is about 330 MeV/c and its direction is unknown. A small contribution to the upper shoulder of the observed missing mass distribution is attributed to $B \to \overline{D}^{**} \ell^+ \nu_\ell$ decay followed by $\overline{D}^{**} \to \overline{D}^* \pi$.

Table 5: Branching fractions for exclusive B semileptonic decays. The measurements assume that $f_{+-} = f_{00} = 0.5$, where f_{+-} and f_{00} are the branching fractions of the $\Upsilon(4S)$ to B^+B^- and $B^0\overline{B}^0$. Measurements with an asterisk (*) either use more recent values of D and D^* branching fractions or have been corrected. Those with a dagger (†) used early D^* branching fractions, but, due to the complexity of the analysis procedure, are difficult to correct. These points are discussed in the review by Stone (see text). The ARGUS measurement of $B \to \overline{D}^{**} \ell^+ \nu_\ell$ assumes a set of D^{**} states distributed according to the ISGW model. The limits on $b \to u$ semileptonic decays from CLEO are based on efficiencies calculated using the ISGW model; other models give different lepton energy and q^2 distributions and hence somewhat different efficiencies.

Mode	Experiment	Ref.	Branching fraction
$B^0 \to D^- \ell^+ \nu_\ell$	ARGUS*	[27]	$(2.0 \pm 0.7 \pm 0.6)\%$

$B^+ \to \omega \ell^+ \nu_\ell$	CLEO-II	[32]	$< 2.1 \times 10^{-4}$ (90% CL)
$B^+ \to \rho^0 \ell^+ \nu_\ell$	CLEO-II	[32]	$< 2.1 \times 10^{-4}$ (90% CL)
$B^0 \to \rho^- \ell^+ \nu_\ell$	CLEO-II	[32]	$< 4.1 \times 10^{-4}$ (90% CL)
$B^0 \to \pi^- \ell^+ \nu_\ell$	CLEO-II (prelim.)	[17]	$< 3.3 \times 10^{-4}$ (90% CL)

In the second method, first employed by ARGUS, the $\overline{D}^*$ in $B \to \overline{D}^* \ell^+ \nu_\ell$ decay is identified using only the soft pion from the $\overline{D}^* \to \overline{D}\pi$ decay (partial reconstruction). Due to the small energy release in this process, both the energy and the direction of the $\overline{D}^*$ can be estimated from the soft pion's momentum alone. This technique has a large statistical advantage over the method in which both the $\overline{D}^*$ and the $\overline{D}$ are completely reconstructed.

Although $B \to \overline{D} \ell^+ \nu_\ell$ decay has a substantial branching fraction, measurements to date have suffered from poor statistics and the difficulty of dealing with feed-down from $B \to \overline{D}^* \ell^+ \nu_\ell$. Several ARGUS and CLEO-I measurements of $B \to \overline{D} \ell^+ \nu_\ell$ and $B \to \overline{D}^* \ell^+ \nu_\ell$ were extracted using early D and D^* branching fractions, some of which were quite far from their present values. Stone [1] has used more recent D^* and D and branching fractions [25,26] to correct these measurements when possible. The values marked with an asterisk (*) in Table 5 use the same method as Stone but with the updated PDG 1994 $D^0 \to K^- \pi^+$ branching fraction. Together, $B \to \overline{D}^* \ell^+ \nu_\ell$ and $B \to \overline{D} \ell^+ \nu_\ell$ account for about two-thirds of the inclusive semileptonic rate. There is evidence that part of the remainder is due to $B \to \overline{D}^{**} \ell^+ \nu_\ell$ decay, where D^{**} represents a mixture of p-wave and radially excited D mesons.

Searches have also been made for exclusive $B \to X_{\overline{u}} \ell^+ \nu_\ell$ decays. For these decays, unlike $B \to X_{\overline{c}} \ell^+ \nu_\ell$, model predictions [13] indicate that the rate should be distributed over many exclusive channels, with no dominant modes. The decays with the largest expected branching fractions are $B^0 \to \rho^- \ell^+ \nu_\ell$, $B^+ \to \rho^0 \ell^+ \nu_\ell$, and $B^+ \to \omega \ell^+ \nu_\ell$, which in the quark model are predicted to occur in the ratio 2:1:1. Furthermore, these modes should have hard lepton-momentum spectra, so that there is good efficiency for these decays in the endpoint region, where the backgrounds from $B \to X_{\overline{c}} \ell \nu$ are smallest. CLEO has searched for all three modes but has found no significant signals, leading to the upper limits given in Table 5. These limits can be converted into model-dependent upper limits on $|V_{ub}/V_{cb}|$. The limit for the ISGW model (correcting the result to $\tau_B = 1.49$ ps) is $|V_{ub}/V_{cb}| < 0.12$ (90% CL), consistent with the CLEO-II inclusive measurement (using the ISGW model) given in Table 4.

Measurement of $|V_{cb}|$ from $B \to \overline{D}^* \ell^+ \nu_\ell$

Three types of measurements can be used to determine $|V_{cb}|$: (1) inclusive semileptonic rate (discussed in Section IV.1), (2) the rates for $B \to \overline{D} \ell^+ \nu_\ell$, or (3) $B \to \overline{D}^* \ell^+ \nu_\ell$, or a partial rate for $B \to \overline{D}^* \ell^+ \nu_\ell$ corresponding to the kinematic configurations in which the D^* recoils slowly. The $B \to \overline{D}^* \ell^+ \nu_\ell$ mode is especially well suited to measuring $|V_{cb}|$. Using HQET, the rate for this process can be accurately predicted (as a function of $|V_{cb}|^2$) for the kinematic configuration in which the D^* is produced at rest and the lepton and neutrino are back to back in the B rest frame. This configuration occurs when $q^2 = q^2_{\rm max} = (m_B - m_{D^*})^2$. The light constituents of the initial B meson are then essentially undisturbed by the $B \to X_{\overline{c}} \ell^+ \nu_\ell$ transition, at least in the limit where the b and c quark masses are taken to be very large compared with Λ_{QCD}.

In this large-mass limit, all of the $B \to \overline{D}^* \ell^+ \nu_\ell$ form factors are related to a single form factor, the Isgur-Wise function, which depends only on the relative four-velocities of the initial and final hadrons: $\xi = \xi(v_B \cdot v_{D^*})$. Note that $v_B \cdot v_{D^*} = \gamma_{D^*}$, where the relativistic factor γ_{D^*} is measured in the B-meson rest frame. The quantity $v \cdot v'$, where v is the initial and v' is the final meson four-velocity, is often called w or y in the literature. It is linearly related to q^2 by

$$w = v \cdot v' = \frac{M^2 + m^2 - q^2}{2Mm} , \tag{2}$$

where M and m are the masses of the parent and daughter mesons.

At zero recoil ($w = 1$ or $q^2 = q^2_{\rm max}$), the normalization of ξ is known, $\xi(1) = 1$, which means that the decay rate in this configuration can be accurately predicted as a function of $|V_{cb}|^2$. Corrections to this picture arise from hard gluon corrections and because the masses of the b and c quarks are not truly infinite. However, the heavy quark symmetry limit prediction for $B \to \overline{D}^* \ell^+ \nu_\ell$ is protected by Luke's theorem [33], which states that, for this process, there are no leading order $(1/m_Q)$ nonperturbative corrections at $w = 1$, where m_Q is the mass of a heavy quark (c or b). As a consequence, the leading corrections to the decay rate prediction arise at order $1/m_Q^2$. The calculation of these corrections, which introduces some model dependence, has been the subject of many investigations. Neubert [2,34] has obtained the result

$$\frac{1}{\tau_B} \cdot \frac{d\mathrm{B}(B^0 \to D^{*-} \ell^+ \nu_\ell)}{dw} = \frac{G_F^2}{48\pi^3} m_{D^*}^3 (m_B - m_{D^*})^2 \eta_A^2 \sqrt{w^2 - 1} (w+1)^2 \left[1 + \frac{4w}{w+1} \frac{1 - 2wr + r^2}{(1-r)^2} \right] |V_{cb}|^2 \widehat{\xi}(w)^2 , \tag{3}$$

where $r = m_{D^*}/m_B$, $\eta_A = 0.99$, and

$$\widehat{\xi}(1) = 1 + \delta_{(1/m^2)} = 1.00 \pm 0.04 . \tag{4}$$

(The values for η_A and $\widehat{\xi}(1)$ are preliminary.) The unknown function $\widehat{\xi}(w)$ is related to $\xi(w)$, as discussed by Neubert [2], but includes symmetry breaking corrections. These predictions can be used to determine $|V_{cb}|$ from the measured rate at zero recoil. Strictly speaking, there is no phase space for this configuration, so in practice one has to measure the rate in a small region near $w = 1$. (A new estimate of the corrections to the heavy-quark symmetry limit by Shifman, Uraltsev, and Vainshtein [19] gives a lower value of $\widehat{\xi}(1)$ and a higher value of $|V_{cb}|$.)

Unfortunately, both CLEO and ARGUS have difficulty in measuring the rate in this region because the decay of the slow-moving D^* produces a very slow pion, which is difficult to detect with high efficiency. The rate at zero recoil is therefore obtained by measuring the rate as a function of w and then extrapolating to $w = 1$. This procedure introduces some model dependence because HQET does not predict the w dependence of the form factors, which involves nonperturbative QCD physics. (Several groups are using lattice QCD to predict the w dependence and are beginning to obtain interesting results [35].) Because the w range is small, however, the form factors are expected to have only modest variation, which is approximately linear. CLEO and ARGUS use a variety of functional forms to parametrize the w dependence. The different extrapolations to $w = 1$ lead to a range of values for $|V_{cb}|$, some of which are listed in Table 6. The systematic errors on the CLEO measurements are due to uncertainties in the soft-pion detection efficiency, smearing effects, background ($B \to \overline{D}^{**}\ell^+\nu_\ell$), and sensitivity to the values of the form factors. As discussed for the exclusive branching ratios, these measurements assume $\mathrm{B}\left(\Upsilon(4S) \to B^0\overline{B}^0\right) = 0.5$. It should be noted that $|V_{cb}|$ can also be obtained from the total rates for $B \to \overline{D}\ell^+\nu_\ell$ and $B \to \overline{D}^*\ell^+\nu_\ell$. The theoretical predictions, however, are less reliable than those for the zero-recoil configuration of $B \to \overline{D}^*\ell^+\nu_\ell$.

Table 6: Measurements of $|V_{cb}|$ and $\widehat{\rho}^2$ using the decay $B \to \overline{D}^*\ell^+\nu_\ell$ and HQET predictions. The ARGUS measurements of $|V_{cb}|$ have been corrected to a B lifetime of 1.49 ps.

Form factor measurements

Both ARGUS and CLEO have used measurements of kinematic distributions to obtain information on the form factors for $B \to \overline{D}^*\ell^+\nu_\ell$. In contrast to D-meson semileptonic decays, however, one expects the predictions of heavy quark effective theory to be applicable to $B \to X_c\ell^+\nu_\ell$. Here, both the initial- and final-state quarks are heavy compared with the typical hadronic scale set by Λ_{QCD}. With sufficiently large data samples, the $B \to \overline{D}^*\ell^+\nu_\ell$ decay should provide useful tests of HQET predictions. Ideally, one would determine the q^2 dependence of each of these form factors with minimal assumptions. In practice, due to the limited data samples so far available, experiments have taken the shapes of the q^2 dependence from models. The ratios of the form factors at a particular q^2, usually $q^2_{\max}$, are then obtained from fits to observed kinematic distributions.

Both ARGUS and CLEO have extracted the values of two key observables that can be related to the values of the form factors. The first of these is A_{FB}, the forward-backward asymmetry of leptons in the virtual-W rest frame (see Section II). The nonzero value of A_{FB} is a consequence of the parity-violating $V-A$ coupling, which results in more leptons being produced in the hemisphere opposite the D^* momentum vector than in the hemisphere containing it. The second observable is the polarization parameter α (see Section II). It is important to recognize that although both A_{FB} and α are defined as integrals over all of phase space, the lepton asymmetry and the D^* polarization are actually functions of q^2. Thus, measurements for which the acceptance over phase space is not uniform must be either corrected or compared with theoretical predictions incorporating the same acceptance.

Table 7 compares theoretical predictions of A_{FB} and α from Neubert [2] with measurements from ARGUS and CLEO. The measurements, however, are slightly different. In the CLEO-II measurement, A_{FB} is an average over all decays for which $p_\ell > 1.0$ GeV/c. In ARGUS, the same cut is used (for both A_{FB} and α), but the effect of this cut is removed using theoretical models. CLEO-I has also measured [36] $\alpha = 0.65 \pm 0.66 \pm 0.25$ for $p_\ell > 1.4$ GeV/c.

The dependence of the CLEO results on the momentum cuts disappears only when the form factor ratios are calculated (for each model) using a least-squares fit that incorporates the acceptance. In the ARGUS analysis, on the other hand, the kinematic distributions are fitted directly to models in which the only free parameters are form factor ratios. The values of A_{FB} and α are then derived from each model using the fitted values for the form factors. Thus, the dependence of A_{FB} and α on the lepton-momentum cut is removed model by model. ARGUS finds that their values of A_{FB} and α are insensitive to the model used. (They do not quote the form factor ratios obtained from the fits.)

The observation of a positive value for A_{FB} is consistent with predictions of form factor models that assume $V-A$ couplings at both W-boson vertices. CLEO has shown that models in which the hadronic current has a $V+A$ structure do not describe the data well, assuming that $V-A$ is still used for the leptonic current [37]. (However, the measurement of A_{FB} cannot rule out the case in which both the hadronic and leptonic currents are $V+A$.) The predicted value of A_{FB} is a function of ρ^2, the slope of the Isgur-Wise function, as can be seen from Table 7.

Table 7: Comparison of theoretical and experimental values of the D^* polarization parameter α and the lepton forward-backward asymmetry A_{FB} in $B \to \overline{D}^* \ell^+ \nu_\ell$ decay. The theoretical values, which depend on the form factor slope $\rho^2_{A_1}$, were obtained by Neubert using HQET with the assumption of a pole form for the form factor.

$\rho^2_{A_1}$	A_{FB}	A_{FB} ($p_\ell > 1$ GeV/c)	α
1.1	0.22	0.16	1.33
0.8	0.22	0.16	1.44
0.5	0.22	0.15	1.55
Expt.	$0.20 \pm 0.08 \pm 0.06$ ARGUS [29]	$0.14 \pm 0.06 \pm 0.03$ CLEO-II [37]	$1.1 \pm 0.4 \pm 0.2$ ARGUS [29]

CLEO has performed least-squares fits using the measured values of A_{FB}, α (averaged over CLEO and ARGUS results), and the histogram of $d\Gamma/dq^2$ (also averaged over CLEO and ARGUS measurements), to obtain values for the ratios of the $B \to \overline{D}^* \ell^+ \nu_\ell$ form factors at $q^2_{\rm max}$. The results of these fits are given in Table 8, together with the predictions of several models. Although the values of the form factor ratios are in agreement with predictions, the precision is not yet sufficient to distinguish among the models.

Table 8: Measurements and predictions for ratios of the form factors for $B \to \overline{D}^* \ell^+ \nu_\ell$, evaluated at $q^2 = q^2_{\rm max}$. The two fits (a) and (b) correspond to different assumptions for the q^2 dependence of the form factors. The fits given in the CLEO paper quoted here combined the A_{FB} measurement from CLEO with ARGUS and CLEO measurements of α and $d\Gamma/dq^2$.

Conclusions on B semileptonic decays

Knowledge of B semileptonic decays is advancing rapidly, and many of the values given in this review are likely to be superseded in the near future. The inclusive B semileptonic branching fraction is already one of the most precisely measured quantities in B physics, and experimental errors should continue to improve. Important progress is being made in minimizing the model dependence of this measurement by using dilepton events. Knowledge of the exclusive semileptonic branching ratios is still rather poor: only $B \to \overline{D}^* \ell^+ \nu_\ell$ is known with reasonable precision, and exclusive $B \to X_{\overline{u}} \ell^+ \nu_\ell$ transitions have not yet been measured. By our next edition, this situation may well have changed.

Semileptonic B decays provide important information on $|V_{cb}|$ and $|V_{ub}|$. The inclusive $B \to X_{\overline{c}} \ell^+ \nu_\ell$ decay rate is roughly one hundred times that for $B \to X_{\overline{u}} \ell^+ \nu_\ell$ decays, so that $|V_{ub}|$ is much harder to measure. Furthermore, the model dependence is more severe for measurements of $|V_{ub}|$ than for $|V_{cb}|$. The $B \to X_{\overline{u}} \ell^+ \nu_\ell$ signal is statistically significant only in a very small part of phase space, the lepton spectrum endpoint region, in which model predictions are questionable. In the future, measurements of the q^2 distribution in both inclusive and exclusive $B \to X_{\overline{u}} \ell^+ \nu_\ell$ decays should help to reduce the model dependence, and lattice QCD may be important for improving $|V_{ub}|$ determinations. Finally, because both quarks are heavy in a $B \to X_{\overline{c}} \ell^+ \nu_\ell$ transition, one can use the tools of heavy quark effective theory to predict decay rates. Using $B \to \overline{D}^* \ell^+ \nu_\ell$ in the kinematic region where the D^* has only a small recoil velocity, one can determine $|V_{cb}|$ with relatively little model dependence, even though the data samples are not yet large enough to fully realize the potential of this approach. The methods of HQET may also lead to a precise determination of $|V_{cb}|$ from the inclusive semileptonic rate.

It is important to test HQET in detail. Although form factor measurements are roughly consistent with HQET predictions, the experimental uncertainties are too large at present to allow a stringent test. And although heavy quark symmetry can relate different form factors to the Isgur-Wise function, only nonperturbative techniques such as lattice QCD can actually predict the q^2 dependence of this function. One can expect significant progress in all of these areas during the next few years.

16. This average b-hadron lifetime, also used in Sec. 28 on "The Cabibbo-Kobayashi-Maskawa Mixing Matrix," is based on results from LEP experiments and CDF and includes contributions from B_s^0 mesons and b-baryons, which are not produced at the $\Upsilon(4S)$. However, these contributions are thought to be relatively small (LEP experiments typically assume nominal production ratios given by $B^+ : B^0 : B_s^0 : b$-baryon= 0.40 : 0.40 : 0.12 : 0.08), and their lifetimes are similar to those of B^+ and B^0 mesons. Alternatively, one can use the less precisely measured B^+ and B^0 lifetimes ($\tau_{B0} = 1.50 \pm 0.11$ ps and $\tau_{B+} = 1.54 \pm 0.11$ ps) from CDF and LEP experiments.

$B^{\pm}$

B HADRON MEAN LIFE

These measurements of the B mean life are averages over bottom particles produced, weighted by their semileptonic branching ratios, unless otherwise stated. Only the measurements at high energy are averaged since it is expected that the admixtures of B hadrons from Z decay and 1.8 TeV $p\overline{p}$ collisions should should not differ significantly.

[7] ABE 93J analyzed using $J/\psi(1S) \to \mu\mu$ vertices.
[8] ACTON 93C analysed using $D/D^*\ell$anything event vertices.
[9] ACTON 93L and ADRIANI 93K analyzed using lepton (e and m) impact parameter at Z.
[10] BUSKULIC 93O analyzed using dipole method plus lepton (e and μ) impact parameter at Z.
[11] BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.
[12] Using $Z \to J/\psi(1S)X$, $J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
[13] ABREU 93D data analyzed using $D/D^*\ell$anything event vertices.
[14] ABREU 93G data analyzed using charged and neutral vertices.
[15] ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
[16] ACTON 92 is combined result of muon and electron impact parameter analyses.
[17] BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.
[18] Using $Z \to e^+X$ or μ^+X, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
[19] Using $Z \to eX$ or μX, DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
[20] HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
[21] LYONS 90 combine the results of the B lifetime measuresments of ONG 89, BRAUNSCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
[22] We have combined an overall scale error of 15% in quadrature with the systematic error of ±0.7 to obtain ±2.1 systematic error.
[23] Statistical and systematic errors were combined by BROM 87.

B^+ DECAY MODES

B^- modes are charge conjugates of the modes below.

Only data from $\Upsilon(4S)$ decays are used for branching fractions, with rare exceptions. The branching fractions listed below assume a 50:50 $B^0\overline{B}^0$:B^+B^- production ratio at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would effect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B DECAY MODES

$\overline{B}$ modes are charge conjugates of the modes below.

For the following modes, the charge of B was not determined. The measurements are for an admixture of B mesons at the $\Upsilon(4S)$ unless otherwise indicated by a footnote and a "$\overline{b}$" instead of "B" in the initial state.

Semileptonic and leptonic modes

Γ_{120}	$B \to e^+\nu_e$anything	[b]	(10.4 ± 0.4)	%		S=1.3

Γ_{172}	$\overline{b} \to \mu^+ \mu^-$ anything	$B1$	[f] < 5.0 × 10^{-5}		CL=90%

[a] ℓ indicates e or μ mode, not sum over modes.

[b] These values are model dependent. See note on "Semileptonic Decays" in these Full Listings.

[c] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[d] B^0, B^+, B_s^0, and B baryon states not separated.

[e] The value is for the sum of the charge states indicated.

[f] B^0, B^+, and B_s^0 not separated.

B^+ BRANCHING RATIOS

$\Gamma(\overline{D}^0 \ell^+ \nu)/\Gamma_{\text{total}}$ Γ_1/Γ

$0.041 \pm 0.008^{+0.008}_{-0.009}$		[27] FULTON	91	CLEO	$e^+e^- \to \Upsilon(4S)$

[25] ALBRECHT 92C reports 0.058 ± 0.014 ± 0.013. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). Assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$.

[26] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[27] Assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$. Uncorrected for D and D^* branching ratio assumptions.

0.005 ± 0.002 ± 0.003		7	[46] ALBRECHT	87C	ARG	$e^+e^- \to \Upsilon(4S)$

[42] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II B($D^*(2010)^+ \to D^0\pi^+$) and absolute B($D^0 \to K^-\pi^+$) and the PDG 1992 B($D^0 \to K^-\pi^+\pi^0$)/B($D^0 \to K^-\pi^+$) and B($D^0 \to K^-\pi^+\pi^+\pi^-$)/B($D^0 \to K^-\pi^+$).

[43] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses the Mark III branching fractions for the D.

[44] BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

[45] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D and $D^*(2010)$. The authors also find the product branching fraction into $D^{**}\pi$ followed by $D^{**} \to D^*(2010)\pi$ to be $0.0014 \,^{+0.0008}_{-0.0006} \pm$ 0.0003 where D^{**} represents all orbitally excited D mesons.

[46] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume B($\Upsilon(4S) \to B^+B^-$) = 55% and B($\Upsilon(4S) \to B^0\overline{B}^0$) = 45%. Superseded by ALBRECHT 90J.

9 ± 5	3	[105] ALAM	86	CLEO	$e^+e^- \to \Upsilon(4S)$

[100] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[101] BORTOLETTO 92 reports $8 \pm 2 \pm 2$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[102] ALBRECHT 90J reports $7 \pm 3 \pm 1$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[103] ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

[104] BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

[105] ALAM 86 assumes $B^{\pm}/B^0$ ratio is 60/40.

0.0018 ±0.0013 ±0.0001	2	[111] ALBRECHT	90J	ARG	$e^+e^- \to \Upsilon(4S)$

[109] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$. The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.80 \pm 0.08 \pm 0.05$. This can be compared with a prediction, using HQET, of 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate.

[110] BORTOLETTO 92 reports $0.0013 \pm 0.0009 \pm 0.0003$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[111] ALBRECHT 90J reports $0.0016 \pm 0.0011 \pm 0.0003$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[186] WEIR 90B assumes B^+ production cross section from LUND.

For all of the decays below, the charge of the decaying B was not determined. Only the admixture of B^0, $\overline{B}{}^0$, B^+, and B^- at the $\Upsilon(4S)$ is used in the averages, except where no $\Upsilon(4S)$ data ave available.

$\Gamma(\ell^+ \nu_\ell \text{anything})/\Gamma_{total}$ Γ_{124}/Γ

Only the experiments at the $\Upsilon(4S)$ are used in the average.

These branching fraction values are model dependent. See the note on "Semileptonic Decays of D and B Mesons, Part II" at the beginning of the B^+ Full Listings.

VALUE	DOCUMENT ID		TECN	COMMENT
0.1043±0.0024 OUR AVERAGE	Includes data from the 2 datablocks that follow this one.			
0.108 ±0.002 ±0.0056	[187] HENDERSON	92	CLEO	$e^+e^- \to \Upsilon(4S)$

[187] HENDERSON 92 measurement employs e and μ. The systematic error contains 0.004 in quadrature from model dependence. The authors average a variation of the Isgur, Scora, Grinstein, and Wise model with that of the Altarelli-Cabibbo-Corbò-Maiani-Martinelli model for semileptonic decays to correct the acceptance.

$\Gamma(e^+ \nu_e \text{anything})/\Gamma_{total}$ Γ_{120}/Γ

Only the experiments at the $\Upsilon(4S)$ are used in the average.

These branching fraction values are model dependent. See the note on "Semileptonic Decays of D and B Mesons, Part II" at the beginning of the B^+ Full Listings.

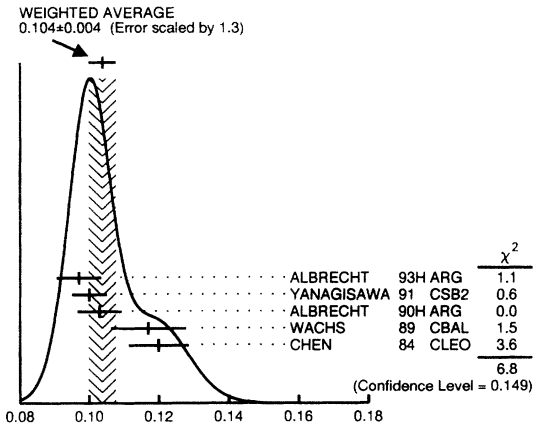
[188] ALBRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[189] YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

[190] ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

[191] Using data above $p(e)$ = 2.4 GeV, WACHS 89 determine $\sigma(B \to e\nu\text{up})/\sigma(B \to e\nu\text{charm}) < 0.065$ at 90% CL.



[192] ABE 93E experiment also measures forward-backward asymmetries and fragmentation functions for b and c.

[193] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.

[194] AKERS 93B analysis performed using single and dilepton events.

[195] ADEVA 91C measure the average B($b \to eX$) branching ratio using single and double tagged b enhanced Z events. Combining e and μ results, they obtain 0.113 ± 0.010 ± 0.006. Constraining the initial number of b quarks by the Standard Model prediction (378 ± 3 MeV) for the decay of the Z into $b\overline{b}$, the electron result gives 0.112 ± 0.004 ± 0.008. They obtain 0.119 ± 0.003 ± 0.006 when e and μ results are combined. Used to measure the $b\overline{b}$ width itself, this electron result gives 370 ± 12 ± 24 MeV and combined with the muon result gives 385 ± 7 ± 22 MeV.

[196] Ratio $\sigma(b \to e\nu\text{up})/\sigma(b \to e\nu\text{charm})$ <0.055 at CL = 90%.

$\Gamma(\mu^+ \nu_\mu \text{anything})/\Gamma_{total}$ Γ_{123}/Γ

Only the experiments at the $\Upsilon(4S)$ are used in the average.

These branching fraction values are model dependent. See the note on "Semileptonic Decays of D and B Mesons, Part II" at the beginning of the B^+ Full Listings.

<0.055	90		KLOPFEN...	83B CUSB	Direct e at $\Upsilon(4S)$

[207] BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \to u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008, respectively.

[208] ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

[209] FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$–2.6 GeV signaling the presence of the $b \to u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \to c\ell\nu) = 10.2 \pm 0.2 \pm 0.7\%$.

[210] ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$–2.6 GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.

[211] The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

[224] BORTOLETTO 92 reports 0.25 ± 0.03 ± 0.04 for $B(D^*(2010)^+ \to D^0\pi^+) = 0.55 \pm 0.04$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.1 \pm 1.3) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. They also use the Mark III $B(D^0 \to K^-\pi^+)$ branching fraction.

[225] ALBRECHT 91H reports 0.348 ± 0.060 ± 0.035 for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.1 \pm 1.3) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+) = 0.0371 \pm 0.0025$.

[226] BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \to K^-\pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. The product branching ratio for $B(B \to D^*(2010)^+)\, B(D^*(2010)^+ \to D^0\pi^+)$ is 0.13 ± 0.02 ± 0.012. Superseded by BORTOLETTO 92.

[227] $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.006$ and $B(D^{*+} \to D^0\pi^+) = 0.6^{+0.08}_{-0.15}$. The product branching fraction is $B(B \to D^{*+}X) \cdot B(D^{*+} \to \pi^+ D^0) \cdot B(D^0 \to K^-\pi^+) = (68 \pm 15 \pm 9) \times 10^{-4}$.

<0.112	90	[255] ALAM	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[253] CRAWFORD 92 result derived from lepton baryon correlations. Assumes all charmed baryons in B^0 and $B^{\pm}$ decay are Λ_c.

[254] ALBRECHT 88E measured $B(B \to \Lambda_c^+ X)\cdot B(\Lambda_c^+ \to pK^-\pi^+) = (0.30 \pm 0.12 \pm 0.06)\%$ and used $B(\Lambda_c^+ \to pK^-\pi^+) = (2.2 \pm 1.0)\%$ from ABRAMS 80 to obtain above number.

[255] Assuming all baryons result from charmed baryons, ALAM 86 conclude the branching fraction is 7.4 ± 2.9%. The limit given above is model independent.

0.076±0.014	[265] ALBRECHT	89K	ARG	$e^+e^- \to \Upsilon(4S)$

[264] ALBRECHT 92O result is from simultaneous analysis of p and Λ yields, $p\overline{p}$ and $\Lambda\overline{p}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89K.

[265] ALBRECHT 89K obtain this result by adding their their measurements (5.5 ± 1.6)% for direct protons and (4.2 ± 0.5 ± 0.6)% for inclusive Λ production. They then assume (5.5 ± 1.6)% for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain (7.6 ± 1.4)%.

$\Gamma(p\overline{p}\text{anything})/\Gamma_{total}$ Γ_{168}/Γ

Includes p and $\overline{p}$ from Λ and $\overline{\Lambda}$ decay.

B^0

$I(J^P) = \frac{1}{2}(0^-)$

Quantum numbers not measured. Values shown are quark-model predictions.

For measurements of the B mean life and for branching ratios in which the charge of the decaying B is not determined, see the $B^\pm$ section.

See the Notes "Experimental Highlights of B Meson Production and Decay" and "Semileptonic Decays of B Mesons" at the beginning of the $B^\pm$ Full Listings and the Note on "B^0-$\overline{B}^0$ Mixing and CP Violation in B Decay" near the end of the B^0 Full Listings.

B^0 MASS

The fit uses m_{B^+} and $(m_{B^0} - m_{B^+})$ to determine m_{B^0}. m_{B^0} data are excluded from the fit because they are not independent. These experiments actually measure the difference between half of E_{cm} and the B mass.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
5279.0±2.0 OUR FIT

5278.2±1.0 ±3.0	40	ALBRECHT	87C	ARG	$e^+e^- \to \Upsilon(4S)$
5279.5±1.6 ±3.0	7	[3] ALBRECHT	87D	ARG	$e^+e^- \to \Upsilon(4S)$

[1] These experiments all report a common systematic error 2.0 MeV. We have artificially increased the systematic error to allow the experiments to be treated as independent measurements in our average. See "Treatment of Errors" section of the Introductory Text.

[2] ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.

[3] Found using fully reconstructed decays with J/ψ. ALBRECHT 87D assume $m_{\Upsilon(4S)} =$ 10577 MeV.

$m_{B^0} - m_{B^+}$

The mass difference measurements are not independent of the $B^\pm$ and B^0 mass measurement by the same experimenters.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
0.34±0.29 OUR FIT Error includes scale factor of 1.1.				
0.34±0.32 OUR AVERAGE Error includes scale factor of 1.2.

2.0 ±1.1 ±0.3	[4] BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[4] BEBEK 87 actually measure the difference between half of E_{cm} and the $B^\pm$ or B^0 mass, so the $m_{B^0} - m_{B^\pm}$ is more accurate. Assume $m_{\Upsilon(4S)} = 10580$ MeV.

$m_{B^0_H} - m_{B^0_L}$

See the B^0-$\overline{B}^0$ MIXING section near the end of these B^0 Listings.

B^0 MEAN LIFE

See $B^\pm$ Full Listings for data on B hadron mean life averaged over species of bottom particles.

[5] ABE 94D measured mean life using fully reconstructed decays.

[6] Data analyzed using $D/D^*\ell$anything event vertices.

[7] ABREU 93G data analyzed using charged and neutral vertices.

[8] WAGNER 90 tagged B^0 mesons by their decays into $D^{*-}e^+\nu$ and $D^{*-}\mu^+\nu$ where the D^{*-} is tagged by its decay into $\pi^-\overline{D}^0$.

[9] AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \to D^{*+} + X$ always.

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

The measurements at high energy are direct lifetime measurements while those at the $\Upsilon(4S)$ are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+.

[10] ABE 94D is a direct measurement using fully reconstructed decays.

[11] Data analyzed using $D/D^*\ell$anything event vertices.

[12] ABREU 93G data analyzed using charged and neutral vertices.

[13] Assumes equal production of B^0 and B^+.

[14] ALBRECHT 92G data analyzed using $B \to D_s\overline{D}$, $D_s\overline{D}^*$, $D_s^*\overline{D}$, $D_s^*\overline{D}^*$ events.

[15] BEAN 87B assume the fraction of $B^0\overline{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

B^0 DECAY MODES

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Decays in which the charge of the B is not determined are in the $B^\pm$ section.

Only data from $\Upsilon(4S)$ decays are used for branching fractions, with rare exceptions. The branching fractions listed below assume a 50:50 $B^0\overline{B}^0$:B^+B^- production ratio at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would effect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

0.060±0.010±0.014		[23] ALBRECHT	89J	ARG	$e^+e^- \to \Upsilon(4S)$
0.070±0.012±0.019	47	[24] ALBRECHT	87J	ARG	$e^+e^- \to \Upsilon(4S)$

[18] ALBRECHT 94 assumes B($D^{*+} \to D^0\pi^+$) = 68.1 ± 1.0 ± 1.3%. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.

[19] ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). We have taken their average e and μ value. They also obtain $\alpha = 2*\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{AF} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}| = 0.036$–0.045 depending on model assumptions.

[20] We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.

[21] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[22] The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45. or $\alpha = 0.7 \pm 0.9$.

[23] ALBRECHT 89J is ALBRECHT 87J value rescaled using $B(D^*(2010)^- \to D^0\pi^-) = 0.57 \pm 0.04 \pm 0.04$. Superseded by ALBRECHT 93.

[24] ALBRECHT 87J assume μ-e universality, the $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.45$, the $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.004 \pm 0.004)$, and the $B(D^*(2010)^- \to D^0\pi^-) = 0.49 \pm 0.08$. Superseded by ALBRECHT 89J.

$\Gamma(\rho^-\ell^+\nu_\ell)/\Gamma_{total}$ Γ_4/Γ

$\ell = e$ or μ, not sum over e and μ modes.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$<4.1 \times 10^{-4}$	90	[25] BEAN	93B	CLE2	$e^+e^- \to \Upsilon(4S)$

[25] BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0\ell^+\nu_\ell)$ and $\Gamma(\omega\ell^+\nu_\ell)$ with this result, they obtain a limit $<(1.6\text{–}2.7) \times 10^{-4}$ at 90% CL for $B^+ \to (\omega \text{ or } \rho^0)\ell^+\nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.8\text{–}0.13$ at 90% CL is derived as well.

<0.0016	90		[33] ALAM	94	CLE2	$e^+e^- \to \Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.007	90		[34] BORTOLETTO	92	CLEO	$e^+e^- \to \Upsilon(4S)$
<0.034	90		[35] BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$
0.07 ± 0.05		5	[36] BEHRENDS	83	CLEO	$e^+e^- \to \Upsilon(4S)$

[33] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[34] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D. The product branching fraction into $D_0^*(2340)\pi$ followed by $D_0^*(2340) \to D^0\pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \to D^0\pi$ is < 0.0004 at 90% CL.

[35] BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%. $B(D^0 \to K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.

[36] Corrected by us using assumptions: $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 50\%$. The product branching ratio is $B(B^0 \to \overline{D}^0\pi^+\pi^-)B(\overline{D}^0 \to K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

[37] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[38] BORTOLETTO 92 reports $0.0040 \pm 0.0010 \pm 0.0007$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.1 \pm 1.3) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[39] ALBRECHT 90J reports $0.0028 \pm 0.0009 \pm 0.0006$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.1 \pm 1.3) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[40] BEBEK 87 reports $0.0028^{+0.0015}_{-0.0012} {}^{+0.0010}_{-0.0006}$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (68.1 \pm 1.3) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.

[41] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.

[42] ALBRECHT 86F uses pseudomass that is independent of D^0 and D^+ branching ratios.

[43] Assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

0.024±0.014	3	[72] BORTOLETTO90		CLEO	$e^+e^- \to \Upsilon(4S)$

[70] ALBRECHT 92G reports $0.014 \pm 0.010 \pm 0.003$ for $B(D_s^+ \to \phi\pi^+) = 0.027$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ and $D^*(2010)^+$ branching ratios, e.g., $B(D^0 \to K^-\pi^+) = 3.71 \pm 0.25\%$, $B(D^+ \to K^-\pi^+\pi^+) = 7.1 \pm 1.0\%$, and $B(D^*(2010)^+ \to D^0\pi^+) = 55 \pm 4\%$.

[71] BORTOLETTO 92 reports $0.016 \pm 0.009 \pm 0.006$ for $B(D_s^+ \to \phi\pi^+) = 0.030 \pm 0.011$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (3.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D and $D^*(2010)$.

[72] BORTOLETTO 90 assume $B(D_s \to \phi\pi^+) = 2\%$. Superseded by BORTOLETTO 92.

0.0040 ±0.0030		[118] ALBAJAR	91E	UA1	$E_{cm}^{p\overline{p}} = 630$ GeV
0.0033 ±0.0018	5	[119] ALBRECHT	87D	ARG	$e^+e^- \to \Upsilon(4S)$
0.0041 ±0.0018	5	[120] ALAM	86	CLEO	Repl. by BEBEK 87

[114] The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[115] BORTOLETTO 92 reports 0.0011 ± 0.0005 ± 0.0003 for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[116] ALBRECHT 90J reports 0.0011 ± 0.0005 ± 0.0002 for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[117] BEBEK 87 reports 0.0035 ± 0.0016 ± 0.0003 for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.99 \pm 0.25) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

[118] ALBAJAR 91E assumes B_d^0 production fraction of 36%.

[119] ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

[120] ALAM 86 assumes $B^\pm/B^0$ ratio is 60/40. The observation of the decay $B^+ \to J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

B^0-$\overline{B}^0$ MIXING

For a discussion of B^0-$\overline{B}^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing and *CP* Violation in *B* Decay" below.

χ_d

This B^0-$\overline{B}^0$ mixing parameter measures the probability (integrated over time) that a produced B^0 (or $\overline{B}^0$) decays as a $\overline{B}^0$ (or B^0), e.g. for inclusive lepton decays

$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0)) / \Gamma(B^0 \to \ell^{\pm} X)$
$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0)) / \Gamma(\overline{B}^0 \to \ell^{\pm} X)$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\bar{b}d)$ or $B_s^0(\bar{b}s)$. They are listed in the B_s^0-$\overline{B}_s^0$ MIXING section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}^0$ fraction and about the ratio of the $B^{\pm}$ and B^0 semileptonic branching ratios (usually that it equals one).

<0.27	90	[202] AVERY	84	CLEO	$e^+e^- \to \Upsilon(4S)$

[196] ALBRECHT 94 reports r=0.194 ± 0.062 ± 0.054. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

[197] BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016^{+0.033}_{-0.028}$.

[198] ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^{\pm}}/\tau_{B^0} = (0.95 \pm 0.14)$ (f_{+-}/f_0).

[199] These experiments see a combination of B_s and B_d mesons.

[200] ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures r=0.21 ± 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.

[201] BEAN 87B measured $r < 0.24$; we converted to χ.

[202] Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If $B^0/B^{\pm}$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from $r < 0.30$ to $r < 0.37$. We converted this limit to χ.

$\Delta m_{B^0} = m_{B_H^0} - m_{B_L^0}$

Δm_{B^0} is a measure of the B^0-$\overline{B}^0$ oscillation frequency in time-dependent mixing experiments.

VALUE (10^{12} $\hbar$ s^{-1})	DOCUMENT ID		TECN	COMMENT
0.51 ±0.06 OUR AVERAGE				
0.508±0.075±0.025	[203] AKERS	94C	OPAL	$e^+e^- \to Z$

$0.52\ ^{+0.10}_{-0.11}\ ^{+0.04}_{-0.03}$	[205] BUSKULIC	93K	ALEP	$e^+e^- \to Z$

[203] AKERS 94C observes the time dependence of B^0-$\overline{B}^0$ mixing using $D^{*\pm}\ell^{\mp}$ events and jet charge.

[204] BUSKULIC 94B observes the time dependence of B^0-$\overline{B}^0$ mixing using dileptons.

[205] BUSKULIC 93K observes the time dependence of B^0-$\overline{B}^0$ mixing using D^{*+} lepton correlations.

$x_d = \Delta m_{B^0}/\Gamma_{B^0}$

This section combines results from the previous two sections.

Time integrated mixing measurements of χ determine this quantity directly via

$$\frac{\Delta m_{B^0}}{\Gamma_{B^0}} = \left(\frac{\chi}{0.5-\chi}\right)^{1/2}$$

while time-dependent mixing measurements determine $\Delta m_{B^0} = m_{B_H^0} - m_{B_L^0}$ which are combined with τ_{B^0} to give

$$\frac{\Delta m_{B^0}}{\Gamma_{B^0}} = \frac{(m_{B_H^0} - m_{B_L^0})\ \tau_{B^0}}{\hbar} .$$

The averaging takes into account the common systematic errors on the LEP experiments due to τ_{B^0}.

[206] Value is their Δm_{B^0} measurement combined with $\tau_{B^0} = (1.50 \pm 0.11)$ ps, the average from this edition. The systematic error on τ_B and is common to experiments bearing this footnote. The averaging takes this into account.

[207] Derived from time-integrated mixing parameter χ.

B^0–$\overline{B}^0$ MIXING AND CP VIOLATION IN B DECAY

(by H. Quinn, SLAC)

The neutral B meson system is like the neutral kaon system, in that two CP-conjugate states exist. The mass eigenstates are mixtures of these states, the mixing being due to box diagrams, shown in Figure 1. The two mass eigenstates can be written

$$|B_L\rangle = p|B_0\rangle + q|\overline{B}^0\rangle \ ,$$
$$|B_H\rangle = p|B_0\rangle - q|\overline{B}^0\rangle \ . \qquad (1)$$

Here H and L stand for Heavy and Light, respectively.

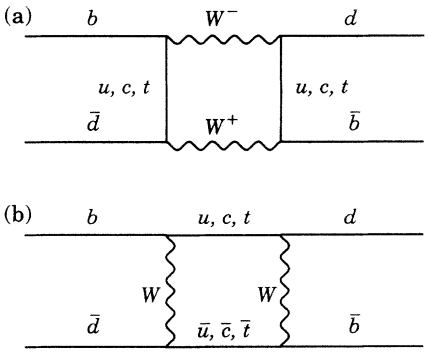

Figure 1: Mixing Diagrams.

Whereas in the kaon case the lifetimes of the two eigenstates are significantly different and the difference in masses between them is small, in the B system it is the mass differences that dominate the physics, and the two states have nearly equal predicted widths (and thus lifetimes).

$$\Gamma = (\Gamma_H + \Gamma_L)/2 \ , \ \Delta\Gamma = \Gamma_H - \Gamma_L \ . \qquad (2)$$

The difference between the widths of the two eigenstates is produced by the contributions from channels to which both B^0 and $\overline{B}^0$ can decay. These have branching ratios of $\mathcal{O}(10^{-3})$ [1]. Furthermore there are contributions of both signs to the difference, so there is no reason that the net effect should be much larger than the individual terms. Conservatively, one expects $\Delta\Gamma/\Gamma \leq 10^{-2}$. Experimentally no effect of a difference in lifetimes has been observed. In what follows, we neglect any effects from $\Delta\Gamma$, except where explicitly stated. We define also

$$M \equiv (M_H + M_L)/2 \ , \quad \Delta M \equiv M_H - M_L \ . \qquad (3)$$

See key on page 1343

The proper time evolution of an initially ($t = 0$) pure B^0 or $\overline{B}^0$ is given by

$$|B^0_{\rm phys}(t)\rangle = \exp(-\Gamma t/2)\exp(-iMt) \times \{\cos(\Delta Mt/2)|B_0\rangle + i(q/p)\sin(\Delta Mt/2)|\overline{B}^0\rangle\} ,$$

$$|\overline{B}^0_{\rm phys}(t)\rangle = \exp(-\Gamma t/2)\exp(-iMt) \times \{i(p/q)\sin(\Delta Mt/2)|B_0\rangle + \cos(\Delta Mt/2)|\overline{B}^0\rangle\} . \quad (4)$$

The probability that an initial B^0 ($\overline{B}^0$) decays as a $\overline{B}^0$ (B^0) is thus

$$P(t) = \tfrac{1}{2}e^{-\Gamma t}(1 - \cos(\Delta Mt) \quad (5)$$

where we have used $|p/q| = 1$ which is true when we neglect the effects of $\Delta\Gamma$. Time-dependent mixing measurements are now beginning to be done; earlier experiments measured the time-integrated mixing, which is parameterized by a parameter χ_d for B_d (*i.e.*, B^0) and χ_s for B_s (*i.e.*, B^0_s). The quantity χ measures the total probability that a created B^0 decays as a $\overline{B}^0$; it is given by

$$\chi_q = \int_0^\infty P_q(t)dt = \frac{x_q^2}{2(1+x_q^2)} . \quad (6)$$

Here quantity x_q is the ratio of the $B^0-\overline{B}^0$ oscillation frequency to the decay rate $x_q = \frac{\Delta M_q}{\Gamma_q}$, $q = d, s$. The value of x_d is about 0.7, not very different from the similar quantity for the K^0 which is 0.48. The value of x_s is expected to be much larger, so that the quantity χ_s will be close to its upper limit of 0.5. This means that one cannot determine x_s accurately by measuring χ_s. It will require excellent time resolution to resolve the time-dependent mixing of the B^0_s system, and thereby determine $\Delta M_{B^0_s}$ [2].

In the B^0–$\overline{B}^0$ mixing section of the B^0 Full Listings, we list the χ_d measurements, most of which come from $\Upsilon(4S)$ data, and the Δm_{B^0} measurements, which come from Z data. We convert both of these sets of measurements and list them in the x_d section. The x_d values obtained from Δm_{B^0} measurements have a common systematic error due to the error on τ_{B^0}. The averaging takes this common systematic error into account.

In the B^0_s–$\overline{B}^0_s$ mixing section of the B^0_s Full Listings, we give measurements of χ_B at high energy and of χ_s obtained by combining the χ_B and χ_d measurements using

$$\chi_B = f_d\chi_d + f_s\chi_s , \quad (7)$$

where f_d and f_s are the fractions of b hadrons that are produced as B^0 and B^0_s mesons respectively. We also convert the average χ_B and χ_d values to χ_s assuming $f_d = 0.391$ and assuming $f_s = 0.117$, obtaining $\chi_s = 0.62 \pm 0.13$, consistent with the maximum allowed value $\chi_s = 0.5$. This χ_s value and error, when converted to an x_s lower limit, yields $x_s > 1.5$. There is now a limit on $\Delta m_{B^0_s}$ from an ALEPH time-dependent B^0_s–$\overline{B}^0_s$ mixing measurement which provides slightly stronger limit, $x_s > 2.0$, than that obtained from the time-independent measurements.

CP violation in B decays—Standard Model predictions: There are three symmetries of the strong interactions that are not conserved in weak processes. These are the symmetries C, charge conjugation, which relates particle to antiparticle, P, parity, which relates a left-handed particle to a similar right-handed one, and T, time-reversal invariance, which relates a process or state to the time-reversed process or state. In all field theories the product of these three operations, CPT, is an exact symmetry of the equations of motion. All weak decays violate P and C, and a very small part of the weak decays also violate the product CP (and thus T). In the Standard Model this CP violation occurs because there is a single phase that remains in the Cabibbo-Kobayashi-Maskawa (CKM) matrix after all possible field redefinitions that can remove such phases have been made. In a minimal two-generation Standard Model no such phase occurs. The presence of CP-violating effects in K decays was interpreted by Kobayashi and Maskawa in 1973 to suggest a third quark generation. Other extensions beyond the minimal Standard Model, such as theories with additional Higgs multiplets, give further ways to introduce CP violation into the theory. Hence it is of great interest to study whether the pattern of CP-violating effects that can be observed in B decays follows the predictions of the minimal Standard Model, or instead requires the introduction of beyond Standard Model effects. In what follows the predictions given are all those of the minimal Standard Model. Cosmologists attempting to understand the process by which the matter-antimatter asymmetry of the universe arose suggest that additional sources of CP violation may be needed to give the observed baryon to photon ratio of the universe [3]. Many models which go beyond the Standard Model indeed introduce such possibilities (see "Beyond Standard Model effects " below.)

The CKM matrix is the matrix of weak couplings in the three generation Standard Model, expressed in the basis of quark mass eigenstates. This matrix, which must be unitary if the three generations are the complete theory, is discussed in some detail in a separate article in this *Review*, here we need only remind ourselves of some notation that is commonly used in this context. The matrix can be written

$$V = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \quad (8)$$

$$\simeq \begin{pmatrix} 1-\lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ \lambda & 1-\lambda^2/2 & A\lambda^2 \\ A\lambda^3(1-\rho-i\eta) & -A\lambda^2 & 1 \end{pmatrix} + O(\lambda^4) .$$

The second expression here is a parameterization due to Wolfenstein [4] with $\lambda = \sin(\theta_{\rm Cabibbo})$, which is frequently used in discussing CP-violating effects. It is given here up to

terms of order λ^3, since higher order terms in λ are negligible for all practical purposes. The unitarity triangle is a simple geometrical representation of a relationship which results from the unitarity of the three-generation CKM matrix V:

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0 \ , \tag{9}$$

(In fact there are nine such relationships given by the unitarity of the CKM matrix, but only three are independent conditions and of those the other two will be more difficult to test because they have one term that is of order λ^2 relative to the others.) The three complex quantities $V_{id}V_{ib}^*$ form a triangle in the complex plane. The three angles of this triangle are labeled

$$\alpha \equiv \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right) \ , \quad \beta \equiv \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right) \ ,$$
$$\gamma \equiv \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right) \ . \tag{10}$$

Figure 2 shows the unitarity triangle, as it is usually drawn, rescaled by the side $V_{cd}V_{cb}^*$. This makes the base of the triangle real and of unit length and the apex of the triangle is then the point(ρ, η) in the complex plane. A major aim of CP-violation studies of B decays is to make enough independent measurements of the sides and angles that this triangle is overdetermined and thus to check the validity of the Standard Model. Already a number of constraints can be made on the basis of present data on x_d, V_{ub}/V_{cb}, and ϵ in K decays. These constraints have been discussed in many places in the literature [5], their exact form depends on the mass of the top quark and on the range of values allowed for the B_K parameter in K decays and the parameter combination $B_B f_B^2$ in B decays.

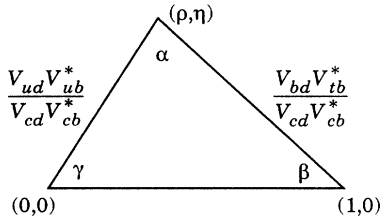

Figure 2: The (rescaled) Unitarity Triangle.

The CKM phases, that is the phases in decay amplitudes which arise because of the phase in the CKM matrix, are often called weak phases, in contrast to the phases which arise from final state rescattering effects which are referred to as strong phases. When one compares the amplitude for a process with that for the related CP conjugate process the weak phase of each contribution changes sign, while the strong phase is unchanged.

$$\mathcal{A} = \Sigma_i \mathcal{A}_i e^{i(\delta_i + \phi_i)} \ , \ \overline{\mathcal{A}} = \Sigma_i \mathcal{A}_i e^{i(\delta_i - \phi_i)} \ . \tag{11}$$

Direct CP violation is a difference in the direct decay rate between $B \to f$ and $\overline{B} \to \overline{f}$ without any contribution from mixing effects. As can readily be seen from Eq. (11), this requires that there be more than one term in the sum Eq. (11) and further that the two terms have both different weak phases and different strong phases. A nonzero result for ϵ' in K decay is a direct CP-violation effect. Direct CP violation can occur both in charged channels and in neutral channels.

In the Standard Model, direct CP violation occurs because there are two classes of diagram that contribute to flavor-changing decays, called tree diagrams and penguin diagrams. Tree diagrams are those in which the W does not reconnect to the quark line from which it was emitted, penguin diagrams are those in which it does. There may be several different tree diagrams for a given process, namely emission from the heavy quark line followed by W decay, W exchange between the initial valence quarks, and/or valence quark-antiquark annihilation to produce the W. However all such contributions which enter a given transition do so with the same CKM (weak) phase. Hence direct CP violation occurs only from interference between tree and penguin type contributions in the Standard Model.

To calculate the size of expected CP-violation effects one begins from the relevant quark decay diagrams. In general weak-decay amplitudes for b quarks can be divided into two factors: a CKM factor given by the CKM-matrix elements that enter at each W vertex, and a kinematic factor from evaluating the Feynman diagram. The penguin diagrams are a loop diagram, and in addition require the emission of a hard gluon (or photon) from the loop to account for the mass difference between the b quark and the s or d quark produced when the W is reabsorbed. The kinematic factor of the penguin diagram is thus suppressed relative to tree diagrams by a factor of order $\alpha(m_b)/4\pi$. It is difficult to make firm predictions based on this argument for the strength of the CP-violating effects in exclusive charged B-decay channels because the relationship between the free-quark decay diagrams and the exclusive meson decay amplitudes is model dependent. Furthermore one cannot reliably predict the strong phases that contribute to the asymmetry. However, due to the suppression of penguin contributions, one does not expect direct CP-violating effects in charged B decays to be more than a few percent effects in the rare (doubly Cabibbo suppressed) decay channels ($b \to q\bar{q}d$, $q = d$ or s), or a few tenths of a percent in the Cabibbo-suppressed modes ($b \to q\bar{q}s$, $q = u, d, s$) [6]. Effects much larger than this would suggest contributions from beyond the Standard Model. Similar results apply for CP asymmetries in the decays of neutral B's to hadronic final states that can only be reached by a definite b flavor.

There are additional CP violating effects in neutral B decays due to interference between the two paths to a given final state f

$$B \to f \text{ or } B \to \overline{B} \to f$$

This is referred to as CP violation due to mixing, or more precisely due to interference between the mixed and unmixed decay paths. It is similar to the effect measured by the parameter ϵ

See key on page 1343

in K decay. The interference between the two contributions can produce rate differences between the decay and its CP conjugate. These effects are of particular interest because they do not depend upon strong phases and hence the measured asymmetries can be directly related to the CKM phases. In any given channel there can also be direct CP violation in addition to the CP violation due to mixing, this complicates the relationship between the measured asymmetry and the CKM parameters. We will briefly discuss later techniques to separate such contributions.

A third type of CP violation, referred to as indirect CP violation, would arise from any difference in the widths $\Delta\Gamma$ of the two mass eigenstates, or more precisely from complex mixing effects that would also give a nonvanishing lifetime difference for the two B mass eigenstates. Such effects are expected to be tiny in the B system. In the particular case of semileptonic decays there are no penguin diagram contributions, and hence, in the approximations used throughout the discussion above, the CP-conjugate decay rates are equal. However there is a possible indirect CP-violating asymmetry in these decays, which would be seen as an charge asymmetry in the same-sign dilepton events produced via mixing from an incoherent state that initially contains a $B^0\overline{B}^0$ pair. This asymmetry vanishes with $\Delta\Gamma$; it is expected to be no larger than 1% [7].

A simple way to distinguish the three types of CP violation is to note that direct CP violation occurs when $|\mathcal{A}/\overline{\mathcal{A}}| \neq 1$, indirect CP violation requires $|q/p| \neq 1$, but CP violation due the interference between decays with and without mixing can occur when both quantities have unit absolute value; it requires only that the ratio of them has a nonzero weak phase [8].

Neutral B decays to CP eigenstates: The decays of neutral B's into a CP eigenstates is of particular interest because many of these decays allow clean theoretical interpretation in terms of the parameters of the Standard Model [9]. We denote such a state by f_{CP}, for example $f_{CP} = J/\psi(1S)K_S$ or $f_{CP} = \pi\pi$, and define the amplitudes

$$\mathcal{A}_{f_{CP}} \equiv \langle f_{CP}|B^0\rangle, \quad \overline{\mathcal{A}}_{f_{CP}} \equiv \left\langle f_{CP}|\overline{B}^0\right\rangle . \tag{12}$$

For convenience let us introduce the quantity $r_{f_{CP}}$

$$r_{f_{CP}} \equiv \frac{q}{p}\frac{\overline{\mathcal{A}}}{\mathcal{A}} . \tag{13}$$

In the limit of no CP violation, $r_{f_{CP}} = \pm 1$ where the sign is given by the CP eigenvalue of the particular state f_{CP}. (Note that in the literature the quantity $r_{f_{CP}}$ is frequently denoted by λ, but we have chosen to avoid this notation as it introduces a confusion with the $\lambda = \sin(\theta_{\rm Cabibbo})$ in the Wolfenstein parameterization of the CKM matrix.)

The time-dependent rates for initially pure B^0 or $\overline{B}^0$ states to decay into a final state f_{CP} at time t is then given by:

$$\begin{aligned}
&\langle f_{CP}|B^0_{\rm phys}(t)\rangle = \\
&\quad \mathcal{A}\exp(-\Gamma t/2)\exp(-iMt) \\
&\qquad \times [\cos(\Delta Mt/2) + ir_{f_{CP}}\sin(\Delta Mt/2)] , \\
&\left\langle f_{CP}|\overline{B}^0_{\rm phys}(t)\right\rangle = \\
&\quad \mathcal{A}\exp(-\Gamma t/2)\exp(-iMt)(p/q) \\
&\qquad \times [i\sin(\Delta Mt/2) + r_{f_{CP}}\cos(\Delta Mt/2)] .
\end{aligned} \tag{14}$$

Thus

$$\begin{aligned}
&\Gamma(B^0_{\rm phys}(t) \to f_{CP}) = \\
&\quad |\mathcal{A}|^2 e^{-\Gamma t}\left[\frac{1+|r_{f_{CP}}|^2}{2} + \frac{1-|r_{f_{CP}}|^2}{2}\right. \\
&\qquad \left.\times\cos(\Delta Mt) - \mathrm{Im}\, r_{f_{CP}}\sin(\Delta Mt)\right], \\
&\Gamma(\overline{B}^0_{\rm phys}(t) \to f_{CP}) = \\
&\quad |\mathcal{A}|^2 e^{-\Gamma t}\left[\frac{1+|r_{f_{CP}}|^2}{2} - \frac{1-|r_{f_{CP}}|^2}{2}\right. \\
&\qquad \left.\times\cos(\Delta Mt) + \mathrm{Im}\, r_{f_{CP}}\sin(\Delta Mt)\right] .
\end{aligned} \tag{15}$$

The time-dependent CP asymmetry is

$$a_{f_{CP}}(t) \equiv \frac{\Gamma(B^0_{\rm phys}(t) \to f_{CP}) - \Gamma(\overline{B}^0_{\rm phys}(t) \to f_{CP})}{\Gamma(B^0_{\rm phys}(t) \to f_{CP}) + \Gamma(\overline{B}^0_{\rm phys}(t) \to f_{CP})} \tag{16}$$

and thus

$$a_{f_{CP}}(t) = \frac{(1-|r_{f_{CP}}|^2)\cos(\Delta Mt) - 2\mathrm{Im}\,(r_{f_{CP}})\sin(\Delta Mt)}{1+|r_{f_{CP}}|^2} \tag{17}$$

When the small difference in width of the two B states is ignored we can write

$$(q/p)_{B_d} = \frac{(V^*_{tb}V_{td})}{V_{tb}V^*_{td})} , \qquad (q/p)_{B_s} = \frac{(V^*_{tb}V_{ts})}{V_{tb}V^*_{ts})} .$$

and thus

$$q/p = e^{-2i\phi_M} , \tag{18}$$

where $2\phi_M$ denotes the CKM phase of the B–$\overline{B}$ mixing diagram. (Note, Eq. (9) allows us to write the sum of all contributions to the mixing in this form, up to small corrections of order $(m_c^2 - m_u^2)/m_W^2$.) Further, when there is no direct CP violation in a channel that is when all amplitudes that contribute to the decay have the same CKM phase, ϕ_D, then $|\mathcal{A}/\overline{\mathcal{A}}| = 1$. In that case $r_{f_{CP}}$ depends on CKM-matrix parameters only, without hadronic uncertainties, and can be written $r_{f_{CP}} = \pm e^{-2i(\phi_D+\phi_M)}$. Then Eq. (17) simplifies to

$$\begin{aligned}
a_{f_{CP}}(t) &= \mp\mathrm{Im}\,(r_{f_{CP}})\sin(\Delta Mt) \\
&= \pm\sin(2(\phi_M+\phi_D))\sin(\Delta Mt) .
\end{aligned} \tag{19}$$

where the overall sign is given by the CP eigenvalue, ± 1, of the final state f_{CP}. The mixing phase ϕ_M and the decay phase ϕ_D are each convention dependent, that is their value can be changed by redefining the phases of some of the quark fields. However Im $r_{f_{CP}}$ depends on convention-independent combinations of CKM parameters only, and thus from Eq. (19) one can directly relate the measured CP-violating asymmetry to the phase of particular combination of CKM-matrix elements in the Standard Model.

In an e^+e^- B collider running at the $\Upsilon(4S)$ resonance, the initial B system is produced in a coherent state which remains $B^0\overline{B}^0$ until such time as one of the particles decays. The time evolution of the second particle thus begins at the time of the decay of the first. Events where one B decays to a flavor-tagging mode while the other decays to a CP-study mode can be used to reconstruct the dependence of the asymmetry on the time between the tagging decay and the CP-study mode decay. The tagging decay may be later, in which case the event is assigned a negative time. Note that the measurement of time dependence is essential at such a machine since, in the interesting cases where Eq. (19) applies, the time-integrated CP asymmetry vanishes.

Hadronic machines on the other hand produce uncorrelated B and $\overline{B}$ mesons; the time in the above equations is the time between production and decay, and thus is always positive. Time-integrated asymmetries do not vanish in this case. The time evolution of the tagging particle occurs independently and will contribute to wrong sign tags. Such machines produce many more B's than will an e^+e^- B factory. For modes with a clean signature, such as those with a final state $J/\psi(1S)$ or ϕ, hadronic machines can compete with a B factory in measuring CP asymmetries, but for modes such as $\pi\pi$ or $\rho\pi$ the problems of triggering and of backgrounds make such measurements extremely challenging in a hadronic environment.

Extracting CKM parameters from measured asymmetries: In order to relate the measured asymmetries to the CKM-matrix parameters one looks at the CKM elements that appear in the relevant decay amplitudes and in the mixing diagrams. Table 1 gives the result for the various b-quark decay channels. For the penguin contributions the CKM factors given here are obtained by assuming CKM unitarity and neglecting small corrections due to the difference between charm and up quark masses in the loop for $b \to d$ processes, and those due

Table 1: B decay modes for CP studies.

Quark Process	Tree CKM	Leading Penguin CKM	Sample B_d Modes	B_d Angle	Sample B_s Modes	B_s Angle	Comments

(a) Tree and penguin contribute with same weak phase.

(b) Penguin only, rare decays.

(c) Tree and penguin compete. Isospin analysis may allow extraction of α, β, for B_d channels, γ, 0 for B_s, where these angles come from tree and penguin contributions respectively. $K_S\overline{K}_S$ penguin only, except 0 asymmetry.

(d) Ignoring penguin relative to tree.

(e) Ignoring penguin relative to tree, or using isospin analysis.

(f) Self-tagging $K^*(892)$ decay modes can give γ when data from $B_d \to D^0_{CP}$, *i.e.* decays to CP eigenstates, and D^0- or $\overline{D}^0$-identified modes are combined. Similar results for charged $B \to DK$.

(g) Asymmetry in $D^0_{CP}\pi$, $D^0_{CP}K_S$, *etc.* modes is difficult to relate to CKM angles.

$(\dagger)$ $D^0\overline{D}^0$ from rescattering only, rate expected to be small.

See key on page 1343

to terms of higher order in $\lambda = \sin(\theta_{\text{Cabibbo}})$ for $b \to s$ decays. When the decay also involves a K_S in the final state an additional contribution to the phase from the K-mixing phase must be included in relating the measured asymmetry to the CKM parameters.

The columns labeled "Sample B_d Modes" and "Sample B_s Modes" list some of the simplest CP-eigenstate modes for each case. The columns labeled "Angle" show the particular combination of CKM phases $\phi_M + \phi_D$ that is measured by the CP-violating asymmetry in these decays, given as an angle of the unitarity triangle. For most channels the measured asymmetry in a time-dependent measurement is $\pm\sin(2(\phi_M + \phi_D))\sin(\Delta Mt)$ while in a time-integrated measurement the asymmetry is $\pm x_q/(1+x_q^2)\sin(2(\phi_M+\phi_D))$. The sign is given by the CP eigenvalue of the particular final state studied. The exception to these statements is the channel DK discussed below.

The assumptions needed to obtain the results in the "Angle" columns are noted in the comments below the table. Terms of higher order in $\lambda = \sin(\theta_{\text{Cabibbo}})$ have been dropped. Penguin diagrams that occur at the same order of λ as the corresponding tree diagrams are neglected in stating the relationship of the asymmetry to angles in the unitarity triangle. In cases where the tree and penguin diagrams are expected to give comparable contributions with different CKM phases there is no simple relationship between the measured asymmetry and a CKM phase, and thus no entry in the "Angle" columns in Table 1.

The mode $D^0K^*(892)$ is listed even though it is not a CP eigenstate because it has been shown that an analysis of this mode can be used to extract the angle γ. [10]. The same type of analysis can also be applied for charged B decays. However the relationship between the decay asymmetry and the angle is not as simple as Eq. (19) in this case. The result depends on measurements of a number of branching ratios. It will be very difficult to obtain accurate results by this method.

In the case of the $b \to u\bar{u}d$ and $b \to d\bar{d}d$, the penguin contributions occur at the same order in λ as the tree diagrams and are thus are expected to be small compared to them because of the $\alpha(m_b)/\pi$ suppression factor. The result given in Table 1 makes this approximation. If however this expectation proves false, so that the contributions are comparable, one still may be able to extract a measurement of $\sin(2\alpha)$ from the $\pi^+\pi^-$ asymmetry. This is achieved by measuring the rates in several isospin-related channels and using a multiparameter fit to separate tree and penguin contributions to the amplitudes [12]. This will require measuring the decay rate for channel $\pi^0\pi^0$, which will be a challenge. For the $\rho\pi$ decays, if penguins are not negligible, the restrictions due to isospin can again be used to make a multiparameter fit to the ρ-regions of the Dalitz plot for $\pi^+\pi^-\pi^0$ distribution [13]. The interference between different ρ-charge channels is significant and may provide sufficient information to allow the separation of tree and penguin effects and thus extraction of the parameter α. Such analyses at the very least can be used to test whether the penguin contributions are indeed small enough to be neglected in the determination of α.

There are some common decay channels of the B^0 and $\overline{B}^0$ which are not CP eigenstates. For example the channel $J/\psi(1S)K^*(892)$ where the $K^*(892) \to K_S\pi^0$, the final state is not a CP eigenstate because both even and odd relative angular momenta between the $J/\psi(1S)$ and the $K^*(892)$ are allowed. If there is sufficient data one can use angular analysis to separate the different CP final states and measure the asymmetry in each [14]. The same applies in many quasi-two-body decays, such as other vector-vector channels, or those with higher-spin particles in final states. The branching ratio to these channels can be significantly larger than the CP-eigenstate (vector-scalar or scalar-scalar) channels with the same quark content. Such angular analyses may therefore be important in achieving accurate values for the parameters α and β.

Beyond Standard Model effects: The predictions given above are all for the Standard Model. Models beyond the Standard Model may introduce additional contributions to the mixing amplitudes and thereby destroy the relationships given here; in addition they may introduce further direct CP violation.

One model often used as a "straw man" in evaluating the potential of experimental tests of Standard Model predictions is the superweak model, which was one of the earliest proposals for the mechanism of CP violation, in fact prior to the Standard Model [15]. In the modernized version of this model it is assumed that the CKM matrix is real and that all CP-violating effects arise from a contribution to the mixing that comes from beyond the Standard Model. In this case *all* the CP-eigenstate channels for B decay would have the same CP-violating asymmetry (up to a sign which differs for CP-odd and CP-even channels) [16]. This applies even to those channels predicted to have zero asymmetry in the Standard Model, as well as those for which the Standard Model prediction is complicated by the competition between tree and penguin contributions. Observation of significantly different asymmetries in any two neutral B decay CP-eigenstate channels would rule out such a model. In addition the observation of any asymmetry in a charged B decay or a neutral B decay to flavor-tagging final state would be evidence for direct CP violation and would exclude the superweak model, as would an unequivocal nonzero result for the parameter ϵ' in K decays.

Many other models for the physics beyond the Standard Model have been discussed in the literature [17]. The most common additional CP-violating effect is a new contribution to the mixing process, due for example to charged Higgs contributions. The appearance of such contributions in K mixing is already severely restricted by the neutral-K mass difference. However this does not rule out additional contributions to B mixing that would destroy the relationship between the mixing phase ϕ_M and the CKM-matrix elements. This in turn would lead to violations of the predictions given in Table 1 which are based on

this relationship. Models with additional quarks would remove the constraints due to the unitarity of the three-generation mixing matrix and hence lead to the failure of Eq. (9) [18]. (The absence of any fourth light neutrino determined from Z decay rules out only a standard fourth generation with a light neutrino but does not exclude nonstandard fourth generation models.) *Any* observed deviations from the relationships predicted by the Standard Model will provide a window on the nature of physics beyond the Standard Model.

While the discussion above stresses those channels in which there is a simple relationship between any observed asymmetry and the parameters of the CKM matrix in the Standard Model, this does not means that other channels are entirely without interest. To date only the CP violation in the neutral K system has been observed. Any observation of CP violation in B decays would be exciting. The Standard Model prediction is that direct CP-violating asymmetries are likely to be at most a few percent, so large effects in these channels would suggest beyond Standard Model effects. On the other hand, even within the Standard Model the asymmetries due to the interference between decays with and without mixing in the neutral B system can be quite large; current constraints do not rule out cases where Im $(r_{f_{CP}})$ is 1. It is likely that study of the many common decay channels of the B^0 and the $\overline{B}^0$ will greatly expand our understanding of the sources of CP violation.

CP VIOLATION PARAMETERS

$|Re(\epsilon_{B^0})|$

CP impurity in B_d^0 system. It is obtained from $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events at the $\Upsilon(4S)$.

$$Re(\epsilon_{B^0}) \simeq \tfrac{1}{4} a_{\ell\ell} = \tfrac{1}{4} \frac{N(\ell^+\ell^+) - N(\ell^-\ell^-)}{N(\ell^+\ell^+) + N(\ell^-\ell^-)} .$$

VALUE	DOCUMENT ID		TECN	COMMENT
<0.045	[208] BARTELT	93	CLE2	$e^+e^- \to \Upsilon(4S)$

[208] BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $Re(\epsilon_{B^0})$.

[1] These papers report E_γ in the B^* center of mass. The $m_{B^*} - m_B$ is 0.2 MeV higher.

[2] LEE-FRANZINI 90 value is for an admixture of B^0 and B^+. They measure $46.7 \pm 0.4 \pm 0.2$ MeV for an admixture of B^0, B^+, and B_s, and use the shape of the photon line to separate the above value.

[3] HAN 85 is for $E_{cm} = 10.6$–11.2 GeV, giving an admixture of B^0, B^+, and B_s.

B_s^0-$\overline{B}_s^0$ MIXING

For a discussion of B_s^0-$\overline{B}_s^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing and *CP* Violation in *B* Decay" in the B^0 Full Listings above.

χ_s

This B_s^0-$\overline{B}_s^0$ mixing parameter measures the probability (integrated over time) that a produced B_s^0 ($\overline{B}_s^0$) decays as a $\overline{B}_s^0$ (B_s^0). The χ_s values are derived from combining χ_B values measured at high energy (see following datablock) with χ_d values from the $\Upsilon(4S)$. Mixing violates $\Delta B \neq 2$ rule.

[10] From a combination of DELPHI (ABREU 94F), CLEO (ARTUSO 89), and ARGUS (ALBRECHT 92L). Estimated from ABREU 94F figure 7.

[11] From combination of L3 (ADEVA 92C), CLEO (ARTUSO 89), and ARGUS (ALBRECHT 92L). Corresponding limit is > 0.16 at 90%CL.

[12] From combination of UA1 (ALBAJAR 91D), CLEO (BEAN 87B), ARGUS (ALBRECHT 87I), ALEPH (DECAMP 91), and L3 (ADEVA 90P). Corresponding limits are > 0.23 at 95% CL and > 0.27 at 90% CL.

χ_B at high energy

This is a B-$\overline{B}$ mixing measurement for an admixture of B^0 and B_s^0 at high energy.

$$\chi_B = f_d\chi_d + f_s\chi_s$$

where f_d and f_s are the production fractions of B_d^0 and B_s^0 mesons relative to all b-flavored hadrons. Only the measurements at the Z and higher energy $p\bar{p}$ are averaged.

[15] ADEVA 92C uses electrons and muons.

[16] BUSKULIC 92B uses a jet charge technique combined with electrons and muons.

[17] ABE 91G measurement of χ is done with $e\mu$ and ee events.

[18] ALBAJAR 91D measurement of χ is done with dimuons.

[19] ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi} = f_d\chi_d + 0.9f_s\chi_s$.

[20] ACTON 92C uses electrons and muons. Superseded by AKERS 93B.

[21] DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.

[22] ADEVA 90P measurement uses ee, $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.

[23] These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.

[24] The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.

[25] ALBAJAR 87C measured $\chi = (\overline{B}^0 \to B^0 \to \mu^+X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.

[26] Limit is average probability for hadron containing B quark to produce a positive lepton.

See key on page 1343

$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$

$\Delta m_{B_s^0}$ is a measure of the B_s^0-$\overline{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

VALUE (10^{12} $\hbar$ s^{-1})	CL%	DOCUMENT ID		TECN	COMMENT
>1.8	95	[27] BUSKULIC	94B	ALEP	$e^+e^- \to Z$

[27] BUSKULIC 94B determines $\Delta m_{B_s^0}$ from the time dependence of B mixing using dileptons.

$x_s = \Delta m_{B_s^0}/\Gamma_{B_s^0}$

This section combines the results from the previous two sections.

Time integrated mixing measurement of χ determine this quantity directly via

$$\frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = \left(\frac{\chi}{0.5-\chi}\right)^{1/2}$$

while time-dependent mixing measurements determine $\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$ which are combined with $\tau_{B_s^0}$ to give

$$\frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = \frac{(m_{B_{sH}^0} - m_{B_{sL}^0})\,\tau_{B_s^0}}{\hbar}.$$

THE CHARMONIUM SYSTEM

The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.

$\chi_{c0}(1P)$ or $\chi_{c0}(3415)$

$I^G(J^{PC}) = 0^+(0^{++})$

Observed in the radiative decay $\psi(2S) \to \chi_{c0}(1P)\gamma$. Therefore $C = +$. The observed decay into $\pi^+\pi^-$ or K^+K^- implies $G = +$, $J^P = 0^+, 2^+, \ldots$ The angular distribution is consistent with $J = 0$. J^P abnormal excluded by $\pi^+\pi^-$ and K^+K^- decays. $J^P = 0^+$ preferred (FELDMAN 77).

$\chi_{c1}(1P)$ or $\chi_{c1}(3510)$

$I^G(J^{PC}) = 0^+(1^{++})$

Observed in the radiative sequential decay $\psi(2S) \to \chi_{c1}(1P)\gamma$, $\chi_{c1}(1P) \to J/\psi(1S)\gamma$. Therefore, $C = +$. The lack of decays into $\pi^+\pi^-$ or K^+K^- is suggestive of J^P=abnormal. The decays into 4π and 6π imply $G = +$, thus $I = 0$. J=0,2 excluded by angular distribution in the $J/\psi(1S)\gamma$ decay. $J^P = 1^+$ preferred (FELDMAN 77, OREGLIA 82).

$h_c(1P)$ $I^G(J^{PC}) = ?^?(?^{??})$

OMITTED FROM SUMMARY TABLE

Observed in the reaction $\overline{p}p \to J/\psi(1S)\pi^0$ close to the center of gravity of the ^3P_J states and has characteristics consistent with what is expected for the $^1P_1$ state. First indications obtained by BAGLIN 86 in the reaction $\overline{p}p \to J/\psi(1S)X$. Needs confirmation.

$\chi_{c2}(1P)$ or $\chi_{c2}(3555)$ $I^G(J^{PC}) = 0^+(2^{++})$

Observed in the radiative decay $\psi(2S) \to \chi_{c2}(1P)\gamma$. Therefore $C = +$. The observed decay into 4π and 6π imply $G = +$, thus $I = 0$. $J = 0$ is excluded by the angular distribution in the hadronic decays. J^P abnormal excluded by $\pi^+\pi^-$ and K^+K^- decays. $J^P = 2^+$ preferred (FELDMAN 77, OREGLIA 82).

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 13 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 6.9$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\psi(2S)$ $\Gamma(l)\Gamma(e^+e^-)/\Gamma$(total)

This combination of a partial width with the partial width into e^+e^- and with the total width is obtained from the integrated cross section into channel$_l$ in the e^+e^- annihilation. We list only data that have not been used to determine the partial width $\Gamma(l)$ or the branching ratio $\Gamma(l)$/total.

[8] The ABRAMS 75B measurement of Γ_6/Γ_5 and the TANENBAUM 76 result for Γ_6/Γ_7 are not independent. The TANENBAUM 76 result is used in the fit because it includes more accurate corrections for angular distributions.
[9] Not independent of the TANENBAUM 76 result for Γ_6/Γ_7.
[10] Ignoring the $J/\psi(1S)\eta$ and $J/\psi(1S)\gamma\gamma$ decays.
[11] Low statistics data removed from average.

[14] Angular distribution $(1+\cos^2\theta)$ assumed.
[15] Angular distribution $(1-0.189\cos^2\theta)$ assumed.
[16] Valid for isotropic distribution of the photon.
[17] Angular distribution $(1-0.052\cos^2\theta)$ assumed.
[18] Restated by us using $B(\psi(2S) \rightarrow \mu^+\mu^-) = 0.0077$.
[19] The value is normalized to the branching ratio for $\Gamma(J/\psi(1S)\eta)/\Gamma_{total}$.
[20] Restated by us using total decay width 228 keV.
[21] Includes unknown branching fraction $\eta(1440) \rightarrow K\overline{K}\pi$.

$\psi(4040)$

$I^G(J^{PC}) = ?^?(1^{--})$

J^{PC} for the $\psi(4040)$ is known by its production in e^+e^- collisions via single-photon annihilation. I^G is not known, and the interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

$\psi(4415)$

$I^G(J^{PC}) = ?^?(1^{--})$

J^{PC} for the $\psi(4415)$ is known by its production in e^+e^- collisions via single-photon annihilation. I^G is not known, and the interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

$b\bar{b}$ MESONS

NOTE ON WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for $J/\psi(1S)$ and $\psi(2S)$, the full widths of the bound $b\bar{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much smaller than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \tag{1}$$

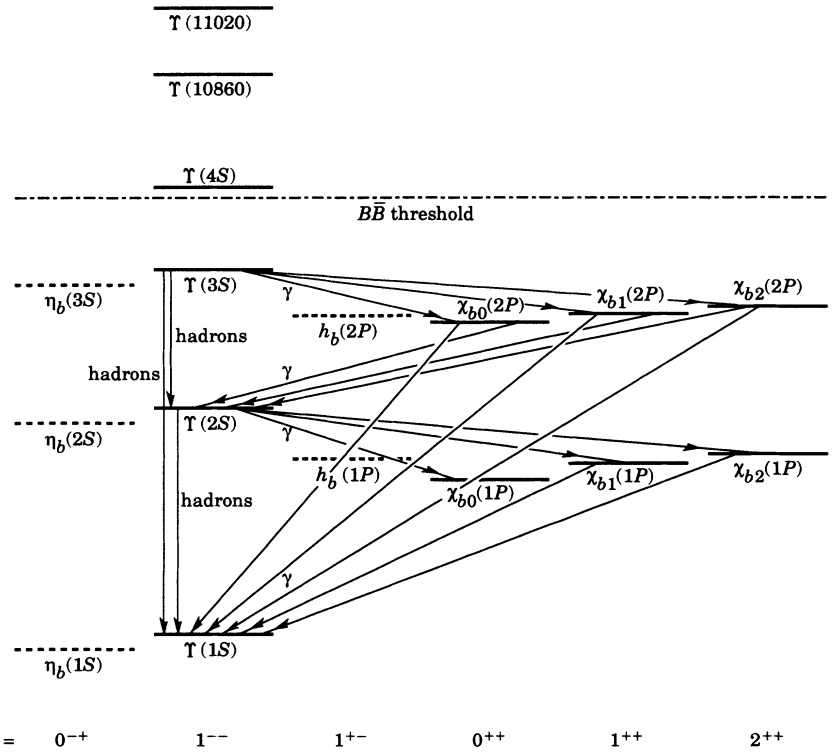
where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction (ℓ = e, μ, or τ). One then assumes e-μ-τ universality and uses

$$\Gamma_{\ell\ell} = \Gamma_{ee}$$

$$B_{\ell\ell} = \text{average of } B_{ee},\ B_{\mu\mu}, \text{ and } B_{\tau\tau} \ . \tag{2}$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only the combination $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$, where $\Gamma_{\rm had}$ is the hadronic partial width and

$$\Gamma_{\rm had} + 3\Gamma_{ee} = \Gamma \ . \tag{3}$$



This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\int_{\rm resonance} \sigma(e^+e^- \to \Upsilon \to \text{hadrons})dE$$

$$= \frac{6\pi}{M^2}\frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma}C_r = \frac{6\pi}{M^2}\frac{\Gamma_{ee}^{(0)}\Gamma_{\rm had}}{\Gamma}C_r^{(0)} \ , \tag{4}$$

where M is the Υ mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1) and contains corrections from all orders of QED for describing $(b\bar{b}) \to e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for the comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone and is about 7% lower than Γ_{ee}. In the past, this distinction had been

THE BOTTOMONIUM SYSTEM

The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b, triplet states Υ and χ_{bJ}. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2$, $L = 1$, $S = 0$, $J = 1$, $PC = +-$. If found, D-wave states would be called $\eta_b(nD)$ and $\Upsilon_J(nD)$, with J = 1,2,3 and $n = 1, 2, 3, 4, \cdots$. For the χ_b states, the spins of only the $\chi_{b2}(1P)$ and $\chi_{b1}(1P)$ have been experimentally established. The spins of the other χ_b are given as the preferred values, based on the quarkonium models. The figure also shows the observed hadronic and radiative transitions.

Meson Full Listings

Bottomonium, $\Upsilon(1S) = \Upsilon(9460)$

overlooked by some authors as pointed out by ALEXANDER 89, BARU 86, COOPER 86, KOENIGSMANN 86, and others.

The Listings give experimental results on B_{ee}, $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$. The entries of the latter quantity have been re-evaluated using consistently the correction procedure of KURAEV 85. The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma(1-3B_{\ell\ell})} \ . \qquad (5)$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1) and no longer the lowest order quantities $\Gamma_{ee}^{(0)}$.

$\chi_{b0}(1P)$ or $\chi_{b0}(9860)$

$I^G(J^{PC}) = ?^?(0 \text{ preferred } ^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

NON-$q\bar{q}$ CANDIDATES

We include here mini-reviews and reference lists on gluonium and other non-$q\bar{q}$ candidates. See also $N\overline{N}$(1100–3600) for possible bound states.

NOTE ON NON-$q\bar{q}$ MESONS

The existence of a gluon self coupling in QCD suggests that, in addition to conventional $q\bar{q}$ meson states, there may exist bound states including gluons: gluonia or glueballs, and hybrids ($q\bar{q}g$). Another example of non-$q\bar{q}$ mesons is multiquark states. For detailed reviews, see, *e.g.*, HEUSCH 86, CLOSE 87, TOKI 88, GODFREY 89, BURNETT 90. Theoretical guidance for the properties of these states is somewhat contradictory, and models often differ in detailed predictions.

Among the signatures naively expected for glueballs are:

(i) No place in $q\bar{q}$ nonets;
(ii) Flavor-singlet couplings;
(iii) Enhanced production in gluon-rich channels such as $J/\psi(1S)$ decay;
(iv) Reduced $\gamma\gamma$ coupling;
(v) Exotic quantum numbers not allowed for $q\bar{q}$ (in some cases).

However, mixing effects, and other dynamical effects such as form factors, may obscure these simple signatures. If the mixing is large, only overpopulation of the spectrum relative to the number of states predicted by the $q\bar{q}$ quark model remains as a clear signal for non-exotic non-$q\bar{q}$ states. Exotic quantum numbers ($J^{PC} = 0^{--}, 0^{+-}, 1^{-+}, 2^{+-}\cdots$) would be the best signature for non-$q\bar{q}$ states.

Lattice gauge theory calculations in the quenched approximation (without quark loops) predict the lightest glueball to be a scalar with a mass of typically 1550±50 MeV (BALI 93). The same calculation finds a tensor glueball mass of 2270±100 MeV, and glueballs with other spin parities, which include the J^{PC}-exotics, are predicted to be still heavier. The inclusion of dynamical quarks will change the predicted masses through couplings to decay channels. Very little is known about the expected widths, which may conceivably be very large.

Hybrid mesons are $q\bar{q}$ states combined with a gluonic excitation (BARNES 82, CHANOWITZ 83, ISGUR 85). Experimentally, these are more attractive than glueballs because they span flavor nonets, and are predicted to have characteristic decay modes (LEYAOUANC 85), and a $J^{PC} = 1^{-+}$ exotic hybrid is expected in all models. The masses of the lightest hybrids are typically predicted to be in the range 1500–2000 MeV.

The third class of non-$q\bar{q}$ states are the multiquark states, which can be either baglike or clusters of mesons (VOLOSHIN 76, JAFFE 77, GUTBROD 79). A subclass of the latter are the deuteronlike meson-meson bound states, or deusons, where the long-range pion exchange is the major source of binding (TORNQVIST 91 and 94, ERICSON 93, MANOHAR 93). Many of the best non-$q\bar{q}$ candidates discussed below lie close to

an important threshold, which suggests that they may be bound states of a meson pair. Examples include the $f_0(980)$ and $a_0(980)$ (close to the $K\overline{K}$ threshold), the $f_1(1420)$ (above $K\overline{K}^*$, thus not a bound state but perhaps a threshold enhancement), the $f_0(1525)$ and $f_2(1520)$ ($\omega\omega$ and $\rho\rho$), the $f_J(1710)$ ($K^*\overline{K}^*$), and the $\psi(4040)$ ($D^*\overline{D}^*$). Many suggestions for such mesonium candidates, involving both light and heavy quarks and binding mechanisms, have appeared recently (WEINSTEIN 90, DOVER 91, BARNES 92, DOOLEY 92).

It should be emphasized that no state has been identified unambiguously as a glueball, hybrid, or multiquark state. The candidates we discuss below are chosen because they are difficult to interpret as conventional $q\overline{q}$ states. Note, however, that we do not see it as our task to discuss theoretical interpretations of the candidates; rather, we merely catalogue the observations of possible relevance.

The scalar-meson sector: The established isoscalars with $J^{PC} = 0^{++}$ are the $f_0(980)$, $f_0(1300)$, $f_0(1370)$, and $f_0(1590)$; the $f_J(1710)$ is an established isoscalar whose spin may be 0. In the quark model, one expects two 1^3P_0 states and one 2^3P_0 ($u\overline{u} + d\overline{d}$)-like state below 1.8 GeV. Thus, there are too many well-established scalars to find a place in the quark model. From further dynamical arguments related to the production or decay, it is very likely that both the $f_0(1590)$ and the $f_J(1710)$ are non-$q\overline{q}$ resonances.

It should, however, be noted that for scalar resonances with strong S-wave thresholds, naive quark model expectations, in particular ideal mixing, must be strongly broken by unitarity. Thus, the physical scalar $q\overline{q}$ spectrum can be very much distorted from naive expectations. Another problem is that mass determinations of a very broad resonance like the $f_0(1300)$ or the $K_0^*(1430)$ are always somewhat dependent on the model and background assumptions. For a detailed discussion of this sector, see our "Note on S-wave $\pi\pi$, $K\overline{K}$, and $\eta\eta$ Interactions."

The $f_0(1590)$, seen in π^-p reactions at 38 GeV/c (BINON 83, BINON 84C, ALDE 87, ALDE 87B), has a peculiar decay pattern for a $q\overline{q}$ state:

$$\pi^0\pi^0 : K\overline{K} : \eta\eta : \eta\eta\prime : 4\pi^0 =< 0.3 : < 0.6 : 1 : 2.7 : 0.8$$

The scalar glueball and the $^3P_0$ $s\overline{s}$ state are both expected near this mass, so we may here be seeing the effects of more than one resonance.

The $f_J(1710)$ (whose spin is uncertain) has been seen mainly in "gluon-rich" $J/\psi(1S)$ radiative decay, where it is copiously produced. In central production, the WA76 experiment (ARMSTRONG 89D) on 300 GeV/c pp interactions n sees a structure at the same mass, but favors spin 2. The $f_J(1710)$ has not been seen in hadronic production ($K^-p \to K\overline{K}\Lambda$) (ASTON 88D), nor in $\gamma\gamma$ fusion. The ratio of the branching fractions in $J/\psi \to \omega f_J$ and $J/\psi \to \phi f_J$ suggests important nonstrange and strange components in this state.

The pseudoscalar sector: The established isoscalars with $J^{PC} = 0^{-+}$ are the η, $\eta\prime(958)$, $\eta(1280)$, and $\eta(1440)$ [which may be two pseudoscalar resonances $\eta(1410)$ and $\eta(1490)$; see the "Note on the $\eta(1440)$"]. In the $q\overline{q}$ model, we expect two 1^1S_0 and two 2^1S_0 pseudoscalars in the 500–1800 MeV range.

Identifying the $\eta(1280)$ with the 2^1S_0 ($u\overline{u} + d\overline{d}$) state seems natural, but it is more problematic to assign one of the two peaks in the $\eta(1440)$ region to the 2^1S_0 $s\overline{s}$ state. The $\eta(1440)$ is observed in $s\overline{s}$-depleted reactions like $\pi^-p \to \eta\pi\pi n$ (ANDO 86) and $\pi^-p \to a_0(980)\pi p$ (CHUNG 85, BIRMAN 88), and is not seen in the $s\overline{s}$-enriched channels like $K^-p \to K^*(892)\overline{K}\Lambda$ (ASTON 87). The fact that ANDO 86 sees the $\eta(1440)$ bump and the $\eta(1280)$ with similar intensities argues for these states being of a similar nature, *i.e.*, radial excitations of the η and $\eta\prime(958)$. However, as there are suggestions of two resonances in the $\eta(1440)$ structure, the experimental situation remains confused and the nature of the $\eta(1440)$ is not well understood.

The axial-vector meson sector: The $q\overline{q}$ model predicts a nonet that includes two isoscalar 1^3P_1 states with masses below about 1.6 GeV. Three such 1^{++} states are known, the $f_1(1285)$, $f_1(1420)$, and $f_1(1530)$, which suggests that one of these is a non-$q\overline{q}$ meson. The $f_1(1420)$ is the most likely candadate; see CALDWELL 89 and the "Note on the $f_1(1420)$." The proximity of the $K\overline{K}^*$ threshold suggests this may be a dominantly $K\overline{K}^*$ mesonium resonance or threshold enhancement (LONGACRE 90, TORNQVIST 91).

The tensor meson sector: The two 1^3P_2 $q\overline{q}$ states are very likely the well-known $f_2(1270)$ and $f_2'(1525)$. There are several other states, which have been suggested as $J^{PC} = 2^{++}$ non-$q\overline{q}$ candidates: the $f_2(1430)$, $f_2(1520)$, $f_J(1710)$, $f_2(1810)$, $f_2(2010)$, $f_2(2300)$, and $f_2(2340)$.

The $f_2(1520)$ is observed by the ASTERIX collaboration (MAY 89) in $p\overline{p}$ P-wave annihilation at 1565 MeV in the $\pi^+\pi^-\pi^0$ channel. Its mass is better determined in the $3\pi^0$ mode by the Crystal Barrel (ANISOVITCH 94) to be 1520 MeV, close to the $\rho\rho$ and $\omega\omega$ thresholds. It has no place in a $q\overline{q}$ scheme, since all nearby $q\overline{q}$ states are already occupied.

Similarly, the $f_J(1710)$ could be composed of $K^*\overline{K}^*$ and $\omega\phi$ (DOOLEY 92), since it lies close to these thresholds. Note that before 1991, the spin of the $f_J(1710)$ was believed to be 2, and that the subsequent spin-0 determination (CHEN 91) has not been confirmed. As already mentioned, in central production WA76 still favours spin 2 for their 1720-MeV structure.

Of the heavier states, the $f_2(1810)$ is likely to be the 2^3P_2 and the three f_2's above 2 GeV could possibly be the 2^3P_2 $s\overline{s}$, 1^3F_2 $s\overline{s}$, and 3^3P_2 $s\overline{s}$, but a gluonium interpretation of one of the three is not excluded. These three f_2 resonances have been observed in the OZI-rule-forbidden process $\pi p \to \phi\phi n$ (ETKIN 88), which has been cited as favoring the gluonium interpretation.

A similar $\phi\phi$ mass spectrum is seen by ARMSTRONG 89B in the Ω spectrometer. The DM2 and MARK-III collaborations see threshold, $\phi\phi$ production, but favor $J^P = 0^-$, not 2^+.

Meson Full Listings

Non-$q\overline{q}$ Candidates, Top and Fourth Generation Hadrons

In $\gamma\gamma \to 4\pi$ near the $\rho\rho$ threshold, TASSO (BRANDELIK 80B, ALTHOFF 82), MARK2 (BURKE 81), CELLO (BEHREND 84E), PLUTO (BERGER 88B), SLAC TPC (AIHARA 88), and ARGUS (ALBRECHT 91F) observe a resonance-like structure. This is dominated by $\rho^0\rho^0$, and the cross section peaks a little above the $f_2(1520)$. This process has not been explained by models in which only conventional resonances dominate. The fact that the $\gamma\gamma \to \rho^+\rho^-$ is small (ALBRECHT 91F quotes 1/4 for the $\rho^+\rho^-/\rho^0\rho^0$ ratio) requires both isospin 0 and 2 for the $\rho\rho$ system. A resonance interpretation in terms of $q^2\overline{q}^2$ states thus requires the presence of a flavor exotic $I = 2$ resonance (ACHASOV 82, 87, 90). For this $\rho\rho$ structure, the 2^{++} partial wave is found to be dominant (BERGER 88B, ALBRECHT 91F), with some 0^{++} at the low-energy end, while $J^P = 0^-$ and 2^- contribute very little.

In $\gamma\gamma \to \omega\rho$, there is also a broad enhancement that peaks near 1.6 GeV (BEHREND 91, WEGNER 91), which is probably composed of several spin parities (BEHREND 91).

Other exotic or non-$q\overline{q}$ candidates: An isovector $\phi\pi^0$ resonance at 1480 MeV has been reported by BITYUKOV 87 in $\pi^-p \to \phi\pi^0 n$; see the $\rho(1450)$. Preliminary indications favor $J^{PC} = 1^{--}$, *i.e.* nonexotic, but the large OZI-rule violating branching ratio $\phi\pi$:$\omega\pi$ seems peculiar for a $(u\overline{u}$-$d\overline{d})$ $I = 1$ $q\overline{q}$ object. However, ACHASOV 88 shows that the threshold effect from the two-step process $\rho(1600) \to K\overline{K}^* \to \pi\phi$ can violate the rule, especially near threshold. No sign of this candidate is seen in $\pi\omega$ (FUKUI 91). In addition, the small coupling to the photon makes an identification with the $\rho(1450)$ difficult (CLEGG 88). More recently DONNACHIE 93, analyzing e^+e^- annihilation and diffractive photoproduction data, suggests there may be 4-quark states near 1100 and 1300 MeV.

Another exotic candidate is the $\hat{\rho}(1405)$ (ALDE 88B, IDDIR 88), seen in the GAMS experiment under the $a_2(1320)$ in $\pi^-p \to \eta\pi^0 n$ with the exotic quantum numbers $J^{PC} = 1^{-+}$. Although the forward-backward asymmetry demands an $\eta\pi$ P-wave, it may be due to a nonresonant amplitude. The Crystal Barrel collaboration has reported results on the corresponding P-wave in $\eta\pi$ seen in $p\overline{p} \to \eta\pi\pi$; they see a much broader effect, which can be explained as nonresonant or as a resonance with $\Gamma \approx 600$ MeV. AOYAGI 93 also notes the $\eta\pi$ P-wave, but its interpretation is unclear.

For another possible 1^{-+} candidate, see the isosinglet $X(1910)$.

A narrow resonance, listed under $K_J^?(3100)$, has been reported at about 3100 MeV (BOURQUIN 86, ALEEV 93) in several $\Lambda\overline{p}$ + pions and $\overline{\Lambda}p$ + pions states. The observation of the doubly charged states $\Lambda\overline{p}\pi^-$ and $\overline{\Lambda}p\pi^+$ implies, assuming the decay is strong, $I = 3/2$, clearly not a $q\overline{q}$ state. In addition, a narrow peak is observed at about 3250 MeV, listed under $X(3250)$, in the "hidden strangeness" combinations containing a baryon-antibaryon pair (ALEEV 93). However, all these observations need confirmation.

$\overline{p}/p$ MASS RATIO, $m_{\overline{p}}/m_p$

A test of *CPT* invariance. GABRIELSE 90 below measures the ratio of *inertial* masses. For a discussion of what may be inferred about the ratio of $\overline{p}$ and p *gravitational* masses, see ERICSON 90; they obtain an upper bound of 10^{-6}–10^{-7} for violation of the equivalence principle for $\overline{p}$'s.

VALUE	DOCUMENT ID		TECN	COMMENT
0.999999977±0.000000042	[2] GABRIELSE	90	TRAP	Penning trap

[2] GABRIELSE 90 also measures $m_{\overline{p}}/m_{e^-}$ = 1836.152660 ± 0.000083 and m_p/m_{e^-} = 1836.152680 ± 0.000088. Both are completely consistent with the 1986 CODATA (COHEN 87) value for m_p/m_{e^-} of 1836.152701 ± 0.000037. We use the CODATA values of the proton and electron masses (they come from an overall fit to a variety of data on the fundamental constants) and don't try to take into account more recent measurements involving the masses.

$(m_p - m_{\overline{p}})$ / $m_{average}$

A test of *CPT* invariance. Calculated from the $\overline{p}/p$ mass ratio, above.

NOTE ON NUCLEON DECAY

(by K. Nakamura, Institute for Cosmic Ray Research, University of Tokyo)

Although there was a rather long pre-GUT history in the search for nucleon decay [1], modern nucleon-decay experiments have been motivated by the SU(5) Grand Unified Theory of Georgi and Glashow [2]. GUTs provide a simple and elegant framework for the unification of strong, weak, and electromagnetic forces, a natural understanding of the Weinberg angle, an explanation of electric-charge quantization, and, above all, a prediction that the nucleon lifetime is finite.

In the minimal SU(5) GUT, nucleon decay is mediated by a supermassive gauge boson, and the dominant decay mode is $p \to e^+\pi^0$. The partial mean life for a particular mode is the total mean life τ divided by the branching fraction B for the mode. The partial mean life for the $p \to e^+\pi^0$ mode is predicted, in the minimal SU(5) GUT, to be $\tau/B = 4.5 \times 10^{29\pm1.7}$ yr [3]. To test this clear and striking prediction, modern nucleon-decay experiments have needed the following: a large mass in order to explore the domain of $\tau/B \gtrsim 10^{30}$ yr, a tracking capability for charged particles, a way to measure visible energy, and particle identification—at least the ability to discriminate between showering (e, γ) and nonshowering $(\mu, \pi^\pm)$ particles.

There are two main techniques. One uses tracking calorimetry with iron plates interleaved by tracking planes; the other uses a water Čerenkov detector. Fig. 1 compares the total and fiducial masses of various nucleon-decay detectors. The 5-year construction schedule of the 50,000-ton water-Čerenkov detector Superkamiokande began in 1991.

Candidate nucleon-decay events are those contained in the detector. Background comes from atmospheric neutrino interactions and has a rate of about 100 kton^{-1}yr^{-1}. The kinematical difference between nucleon decay and atmospheric neutrino interactions provides background rejection. The amount of background contamination depends upon the tightness of the kinematical cuts, which are different for the different decay modes, as well as on detector capabilities such as resolutions of energy and vertex position.

Among the most favorable decay modes to detect is $p \to e^+\pi^0$, because all the final-state particles shower and their energies are well measured. No background contamination is as yet expected for this mode in the current experiments. In the absence of background, the τ/B limit is directly proportional to the detector exposure.

On the other hand, the mode $p \to K^+\overline{\nu}$ is only poorly constrained kinematically. This mode, which unfortunately is the most important one in supersymmetric (SUSY) GUTs, is thus dominated by the atmospheric-neutrino background. In such a background-dominated case, the τ/B limit only improves as the square root of the exposure time.

Fig. 2 summarizes the present limits from the three major detectors (IMB, Kamiokande, and Fréjus) for nucleon partial lifetimes in various modes involving a lepton and a meson. (For limits on other modes, see the Listings.) There is as yet no compelling experimental evidence for nucleon decay, despite the predictions. The observed number of candidate events in each mode is roughly consistent with the atmospheric-neutrino background. For the $p \to e^+\pi^0$ mode, there are no candidate events in the three experiments, and therefore the τ/B limits from these experiments simply add to give the world limit of $\tau/B(p \to e^+\pi^0) > 9 \times 10^{32}$ yr (90% confidence level). Clearly, the minimal SU(5) GUT has already been ruled out. The best background-subtracted limit for the $p \to K^+\overline{\nu}$ mode has been reported by Kamiokande: it is $\tau/B(p \to K^+\overline{\nu}) > 10^{32}$ yr (90% confidence level).

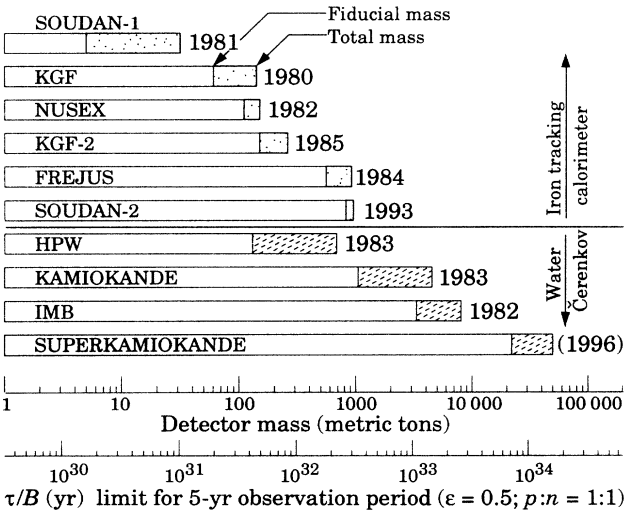

Fig. 1. Nucleon decay experiments. The open bars represent the fiducial masses, while the shaded extensions indicate the total masses. Turn-on dates are at the right. The bottom scale shows the observation limit for the partial lifetime with the assumptions of no background, 50% detection efficiency, and equal numbers of protons and neutrons in the detector material.

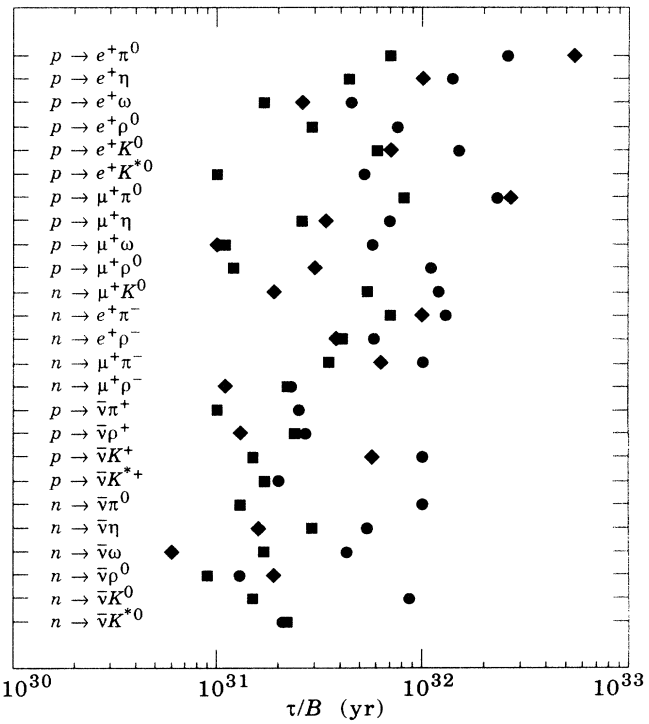

Fig. 2. The 90%-confidence-level lower limits of the nucleon partial lifetime for various nucleon decay modes into lepton + meson, obtained by the IMB (diamonds), Kamiokande (circles), and Fréjus (squares) experiments. For the actual values for these and other modes, see the Listings.

p

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

n

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ****

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1986 edition (Physics Letters **170B**) or in earlier editions.

n MASS

The mass is known much more precisely in u (atomic mass units) than in MeV; see the footnotes. The conversion from u to MeV, 1 u = 931.49432±0.00028 MeV, involves the relatively poorly known electronic charge. The NATARAJAN 93 value, in u, is by far the best, but when converted to MeV differs only negligibly from the 1986 CODATA value, which, for consistency, we stick with.

VALUE (MeV)		DOCUMENT ID		TECN	COMMENT
939.56563±0.00028	[1]	COHEN	87	RVUE	1986 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

LIMIT ON $n\overline{n}$ OSCILLATIONS

Mean Time for $n\overline{n}$ Transition in Vacuum

A test of ΔB=2 baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for $n\overline{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, and ALBERICO 91 for discussions. Direct searches for $n \rightarrow \overline{n}$ transitions using reactor neutrons are cleaner but give poorer limits.

NOTE ON BARYON DECAY PARAMETERS

(by E.D. Commins, University of California, Berkeley)

Baryon semileptonic decays

The typical baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[f_1(q^2)\gamma_\lambda + i\, f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5 q_\lambda \right] B_i \, .$$

Here B_i and $\overline{B}_f$ are spinors describing the initial and final baryons and $q = p_i - p_f$, while the terms in f_1, f_2, g_1, and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V, and g_1 reduces to the axial-vector coupling constant g_A. The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an $e^\pm$ is emitted, and gives a very small correction, which can be estimated by PCAC [4], for $\mu^\pm$ modes. Recoil effects include

weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = (m_i - m_f)/(m_i + m_f) \ , \qquad \text{where}$$

m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to similar formulae for beta decay [6]. For comparison with high-precision experiments, it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and also to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}} \ .$$

The presence of a "triple correlation" term in the transition probability, proportional to $\mathrm{Im}(g_A/g_V)$ and of the form

$$\boldsymbol{\sigma}_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$

for initial baryon polarization or

$$\boldsymbol{\sigma}_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The most general decay amplitude for $J^P = 1/2^+$ hyperons may be written in the form

$$M = G_F m_\pi^2 \cdot \overline{B}_f (A - B\gamma_5) B_i \ ,$$

where A and B are constants [1]. Then the transition rate is proportional to

$$R = 1 + \gamma \hat{\boldsymbol{\omega}}_f \cdot \hat{\boldsymbol{\omega}}_i + (1-\gamma)(\hat{\boldsymbol{\omega}}_f \cdot \hat{\mathbf{n}})(\hat{\boldsymbol{\omega}}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\boldsymbol{\omega}}_f \cdot \hat{\mathbf{n}} + \hat{\boldsymbol{\omega}}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\boldsymbol{\omega}}_f \times \hat{\boldsymbol{\omega}}_i) \ ,$$

where $\hat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\hat{\boldsymbol{\omega}}_i$ and $\hat{\boldsymbol{\omega}}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) Also,

$$\alpha = 2\,\mathrm{Re}(s^* p)/(|s|^2 + |p|^2) \ ,$$

$$\beta = 2\,\mathrm{Im}(s^* p)/(|s|^2 + |p|^2) \ ,$$

and

$$\gamma = (|s|^2 - |p|^2)/(|s|^2 + |p|^2) \ ,$$

where $s = A$ and $p = |\mathbf{p}_f| B/(E_f + m_f)$; here E_f and $\mathbf{p}_f$ are the energy and momentum of the final baryon. The parameters α, β, and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 \ .$$

If the hyperon polarization is $\mathbf{P}_Y$, the polarization $\mathbf{P}_B$ of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma \hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha \mathbf{P}_Y \cdot \hat{\mathbf{n}}} \ .$$

Here $\mathbf{P}_B$ is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\hat{\mathbf{n}}$ from the hyperon rest frame, in which $\hat{\mathbf{n}}$ and $\mathbf{P}_Y$ are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi \ .$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α, ϕ, and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s| e^{i\delta_s} \text{ and } p = |p| e^{i\delta_p} \ ,$$

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p) \ .$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

[17] EROZOLIMSKII 78 says asymmetric proton losses and nonuniform beam polarization may give a systematic error up to 0.003, thus increasing the EROZOLIMSKII 74 error to 0.005. STEINBERG 74 and STEINBERG 76 estimate these systematic errors to be insignificant in their experiment.

n REFERENCES

We have omitted some papers that have been superseded by later experiments. The omitted papers may be found in our 1986 edition (Physics Letters **170B**) or in earlier editions.

NOTE ON N AND Δ RESONANCES

For a lengthier discussion of N and Δ resonances, see our previous edition, Phys. Rev. **D45**, 1 June 1992, Part II. For Argand plots of the partial-wave amplitudes, see our 1990 edition, Phys. Lett. **B239** (1990).

I. Introduction

(by G. Höhler, University of Karlsruhe and R.L. Workman, Virginia Polytechnic Institute and State University)

The excited states of the nucleon have been studied in a large number of formation and production experiments. The conventional Breit-Wigner masses, widths, and elasticities of the N and Δ resonances in the Baryon Summary Table come almost entirely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data (Sec. II). Partial-wave analyses have also been made of much smaller sets of data to get some $N\eta$, ΛK, and ΣK branching fractions, and other branching fractions come from isobar-model analyses of $\pi N \to N\pi\pi$ data (Sec. III). Finally, some $N\gamma$ branching fractions have been determined from photoproduction experiments (Sec. IV).

Table 1 lists all the N and Δ entries in the Baryon Full Listings and gives our evaluation of the status of each, both overall and channel by channel. Only the "established" resonances (overall status 3 or 4 stars) appear in the Baryon Summary Table. We consider a resonance to be established only if it is seen in at least two independent analyses of elastic scattering and if its partial-wave amplitude neither behaves erratically nor has large errors.

The Baryon Full Listings give, in addition to the conventional Breit-Wigner parameters, the positions and residues of the nearest poles of the resonant partial waves on the second sheet of the complex energy plane. These come from $\pi N \to \pi N$ partial-wave analyses and from $\pi N \to N\pi\pi$ isobar-model analyses.

The interested reader will find further discussions in two extensive reviews [1,2], and in the Proceedings of the 5th International Symposium on Meson-Nucleon Physics and the Structure of the Nucleon [3], and more generally in issues of the πN Newsletter (see the note following Sec. II).

(References for this Section are at the end of Section II.)

Table 1. The status of the N and Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

II. Elastic partial-wave analyses and determination of resonance parameters

(by G. Höhler, University of Karlsruhe and R.L. Workman, Virginia Polytechnic Institute and State University)

Our 1992 edition [4] gave a more general discussion. We here treat only new results.

New data: Most of the experimental activity in the past two years was restricted to the energy range from threshold up to the high side of the $\Delta(1232)$ [5]. There are still discrepancies amongst the new data, and final results of some important measurements are not yet available. These data are of interest for the charge splitting of the $\Delta(1232)$, and they are also of some relevance to other resonances, insofar as dispersion relations used in analyses need input from all momenta.

At higher energies, there have been published spin-rotation data measured at LAMPF [6] and at the Petersburg Nuclear Physics Institute [7], and also preliminary integrated πp elastic cross sections above 30° and up to 500 MeV from LAMPF [8].

New πN partial-wave analyses: Three new analyses of elastic data have been made since our 1992 edition. Abaev and Kruglov produced a set of single-energy analyses [9] covering from 160 to 600 MeV laboratory kinetic energy. These fits included experimental total inelastic cross sections and constraints on the tails of small amplitudes from the CMB80 [10] and KH80 [11] solutions. Marked deviations from the KH80 S- and P-wave amplitudes were found. The agreement was better with a new solution from Bugg [12], an analysis restricted to the range below 320 MeV.

The VPI group produced a new set of energy-dependent partial-wave analyses [13] with the improvements of including fixed-t dispersion relation constraints for the forward amplitude and for the invariant amplitudes A and B in the range $0 > t > -0.3$ GeV^2. A grid of solutions was produced for different constraint values of pion-nucleon coupling and S-wave scattering lengths. A χ^2 mapping technique was used to determine which of the solutions gave an 'optimal' fit to both the data and the dispersion relation constraints.

Since the KH80 and CMB80 analyses and the new VPI analysis use dispersion relations as constraints, one may ask if it is justified to use these constraints at a time when QCD is assumed to be the theory of strong interactions. The positive answer was given by R. Oehme [14].

Argand plots for the partial wave amplitudes $T(W)$ which show the results of the CMB80 and KH80 analyses may be found in our 1990 edition [15], and tables of the amplitudes are given in [1].

Conventional resonance parameters: The conventional Breit-Wigner parameters were discussed in detail in our 1992 edition [4]. It is important to keep in mind that the width Γ is the value of $\Gamma(W)$ at the resonance energy $W = M$; it depends on the model used for the energy dependence and on the definition of M. The tabulated elasticities and partial widths are similarly model dependent. The model dependence is the primary reason for the differences in the parameters and their errors quoted by the different groups.

Resonance pole parameters: We add some remarks to the treatment in the previous edition [4]. The resonance pole parameters have the advantage that they are directly related to the definition of a resonance as an unstable intermediate state in a scattering process [16].

Pole parameters for the KH partial wave solutions were determined only recently [17,18]. The method employs not only plots for the speed $|dT/dW|$, which were used in the early seventies, but also Argand plots for dT/dW and fits to the resonance semicircles in the range $M \pm \Gamma/2$ in Argand diagrams for $T(W)$. The parametrization for $T(W)$ agrees with that in [19], but the four parameters of the pole term are treated as constants, since they belong to the pole of $T(W)$. If the background amplitude is elastic, statements made in our 1992 edition [4] concerning the phase of the residue and the elasticity are correct. However, they disagree with the present parametrization in the general case. If the background can be treated as a constant, the model dependence of the pole parameters is weaker than in other methods. This can be assumed for eight of the 4-star resonances [18]. One could try to check if the method proposed in [19] can be applied in practice for a separation of the direct production of inelastic final states and a production by a resonance decay.

For further information on the status of a resonance and on the accuracy of its parameters, there will soon be available a collection of plots [20], calculated from various partial wave analyses.

The parameters of nucleon resonances will remain of interest in the future since they are needed to test various models, such as quark models [21] and Skyrmion models [22]. Finally, they will be needed as soon as these parameters can be calculated from lattice QCD.

III. Inelastic two-body and quasi-two-body reactions

(by D.M. Manley, Kent State University)

Since our 1992 edition, no new data nor partial-wave analyses have been published for the inelastic two-body reactions $\pi N \to N\eta$, $\pi N \to \Lambda K$, and $\pi N \to \Sigma K$. There are recent indications [1] that much of the $\pi N \to N\eta$ data [2] used for the Rutherford partial-wave analysis [3] had poorly determined energies; thus, except for the $N(1535)\,S_{11}$, $N\eta$ branching fractions are omitted from the Baryon Summary Table in this edition. A recent review of these reactions and the quasi-two-body reaction $\pi N \to N\omega$ can be found in Ref. 4.

Essentially all information on quasi-two-body reactions such as $\pi N \to \Delta\pi$ and $\pi N \to N\rho$ comes from isobar-model analyses of $\pi N \to N\pi\pi$ reactions. Since the last edition, the Kent State multichannel resonance analysis has been published [5]. Although couplings from this analysis were listed in the 1992 edition, the present edition includes new, updated estimates for couplings and branching fractions of many resonances observed in two or more isobar-model analyses. A brief review of $\pi N \to N\pi\pi$ analyses can be found in the 1992 edition; for a more recent and extensive review, the interested reader should see Ref. 6.

Since the last edition, there have been two reports [7,8] of resonances observed in $\pi N \to N4\pi$ reactions. One report [7] of $\pi^- p \to p\pi^+\pi^-\pi^-\pi^0$ data from the CERN liquid-hydrogen bubble chamber gives evidence for an N^* resonance with mass 1700 MeV and width 150 MeV, which decays by the channels $p\eta$, $\Delta 2\pi$, $p3\pi$. The other report [8] of $\pi^+ p \to p\pi^+\pi^+\pi^-\pi^0$ data from the ZhVK-205 liquid-hydrogen bubble chamber (Moscow) gives evidence for an N^* resonance with mass 1780 ± 40 MeV and width 250 ± 80 MeV, which decays by the $p\omega$ channel.

IV. Electromagnetic interactions

(by R.L. Crawford, University of Glasgow)

Nearly all the entries in the Listings relating to electromagnetic properties of the N and Δ resonances are couplings for decay to $N\gamma$. These couplings, the helicity amplitudes $A_{1/2}$ and $A_{3/2}$, have been obtained in a large number of partial-wave analyses of single-pion photoproduction, $\gamma N \to \pi N$, on protons and neutrons. The large amount of data has permitted an accurate evaluation of the couplings for many of the resonances with masses below 2 GeV, and has given at least qualitative information about most of the others. Most photoproduction analyses use as input information on the existence, masses, and widths of the resonances from the $\pi N \to \pi N$ analyses, and only determine the $N\gamma$ couplings. A brief description of the various methods of analysis of photoproduction data may be found in our 1992 edition [1].

The Listings omit a number of analyses that are now obsolete. Most of the older results may be found in our 1982 edition [2]. The errors quoted for the couplings in the Listings are calculated in different ways in different analyses and therefore should be used with care. In general, it is likely that the systematic differences between the analyses caused by using

See key on page 1343

different parametrization schemes are more indicative of the true uncertainties than are the quoted errors.

Probably the most reliable analyses are ARAI 80, CRAWFORD 80, AWAJI 81, FUJII 81, CRAWFORD 83, ARNDT 90B, and LI 93. The Listings include our estimates of the couplings, using the results of these analyses. The errors we give are a combination of the stated statistical errors on the analyses and the systematic differences between them. The analyses are given equal weight, except LI 93 is weighted, rather arbitrarily, by a factor of two because its data set is at least 50% larger than those of the other analyses and contains many new high-quality experimental measurements.

The Baryon Summary Table gives $N\gamma$ branching fractions for those resonances whose couplings are considered to be reasonably well established. The $N\gamma$ partial width Γ_γ is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k^2}{\pi}\frac{2M_N}{(2J+1)M_R}\left[|A_{1/2}|^2 + |A_{3/2}|^2\right] .$$

Here M_N and M_R are the nucleon and resonance masses, J is the resonance spin, and k is the photon c.m. decay momentum.

The Listings contain several results for the E2/M1 ratio $(E_{1+}^{(3)}/M_{1+}^{(3)})$ of the $\Delta(1232)$. The analysis of TANABE 85 attempts to distinguish between renormalized and bare couplings; it is, therefore, a model-dependent result and should not be compared directly with the others. Similarly, Christillin and Dillon [3] have made a model-dependent estimate of the ratio. They do not fit directly to data, so their value does not appear in the Listings, but they conclude that the ratio is between zero and −2%. DAVIDSON 90 extracts the K-matrix residues for M_{1+} and E_{1+} using the data from several energy-independent analyses of the $\Delta(1232)$ region. Essentially, they are measuring $\mathrm{Im}(E_{1+}^{(3)})/\mathrm{Im}(M_{1+}^{(3)})$. The value quoted in the Listings is their average over several fits. DAVIDSON 91 uses an effective Lagrangian model to fit to various partial-wave analyses in the $\Delta(1232)$ region.

Christillin and Dillon point out that the spread in predictions may be due to the difference between bare and renormalized couplings. Since the separation of these is essentially model dependent, WORKMAN 92 measures $\mathrm{Im}(E_{1+}^{(3)})/\mathrm{Im}(M_{1+}^{(3)})$ directly from experimental data using the methods of ARNDT 90B. Whereas the other measurements are dependent on rather old partial-wave analyses, WORKMAN 92 uses recent experimental data. They also perform a fit, based on the model of Nozawa *et al.* [4], to extract "bare couplings," and get −3.9%.

The Listings also contain several measurements of the magnetic moment μ_Δ of the $\Delta(1232)^{++}$ from analyses of pion bremsstrahlung, $\pi^+ p \to \gamma\pi^+ p$. NEFKENS 78 is an analysis of UCLA data for pion bremsstrahlung that uses the soft pion model of Pascual and Tarrach [5]. HELLER 87 is a fit to the same data using a nonrelativistic dynamical model that measures the magnetic moment of the "bare" $\Delta(1232)^{++}$. LIN 91B fits the data of NEFKENS 87 and from SIN [6] with an amplitude that includes the anomalous magnetic moment of the $\Delta(1232)$ and is relativistic, gauge invariant, and consistent with the soft photon theorem. The quantity measured is not identical to the "bare" magnetic moment since it does not take into account the effect of loop contributions. BOSSHARD 91 measured the polarized target asymmetry in pion-proton bremsstrahlung and fit it using the model of HELLER 87. The geometry of the experiment was chosen to maximize the sensitivity to μ_Δ.

See our 1992 edition [1] for brief discussions of Compton scattering, $K\Lambda$ photoproduction, and pion electroproduction.

V. Outlook

(by D.M. Manley, Kent State University)

It is anticipated that much new data related to the study of nucleon resonances will come from experiments with electromagnetic probes at CEBAF, which will initially provide beams of electrons and photons with energies up to 4 GeV. Such experiments form the major component of the approved research program for CEBAF's Hall B, which is currently expected to begin operation in Fall, 1996. Other experiments to study nucleon resonances and/or elementary electroproduction or photoproduction reactions will be carried out in CEBAF's Hall A and Hall C, which are expected to being operation in mid-1995 and mid-1994, respectively. The main detector for the Hall-B experiments is the CLAS (CEBAF Large Acceptance Spectrometer), which, with CEBAF's 100% duty cycle, will make possible studies of electroproduction reactions such as $p(e,e'\pi^+)n$, $p(e,e'p)\pi^0$, $d(e,e'\pi^-)pp$, $p(e,e'p)\eta$, and $p(e,e'p)\omega$, among others. This facility will also use tagged photons to make high-precision measurements of the differential cross section for reactions such as π^0, η, and η' photoproduction. These experiments are expected to improve determinations of the electromagnetic couplings of resonances such as the $\Delta(1232)\,P_{33}$, the $N(1520)\,D_{13}$, the $N(1535)\,S_{11}$, and the $N(1680)\,F_{15}$, which have large photocouplings; they are also expected to provide new information about resonances that couple weakly to the πN channel.

CEBAF is not the only laboratory where new experiments to study nucleon resonances will be carried out. For example, the new Bonn continuous beam machine ELSA will combine two large solid-angle detectors, PHOENICS and SAPHIR, with tagged photon facilities to increase our database from various photoproduction processes [1]. Other facilities are or will

be involved in such programs using hadronic beams. For example, plans are underway to study baryon spectroscopy at the Brookhaven National Laboratory AGS [2]. The reactions $\pi^- p \to n\eta$, $K^- p \to \Lambda\eta$, and $K^- p \to \Sigma^0\eta$ will be studied by using the SLAC Crystal Ball to identify multiphoton final states. As by-products of these investigations, new and improved data also will be obtained for $\pi^- p \to n\pi^0$ and for inverse photoproduction on an unstable target, in particular, $K^- p \to \Lambda\gamma$ and $K^- p \to \Sigma^0\gamma$.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1440)$ FOOTNOTES

[1] BAKER 79 finds a coupling of the $N(1440)$ to the $N\eta$ channel near (but slightly below) threshold.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, −2 × imaginary part = 256 MeV, and residue = (78−153i) MeV.

[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[7] An alternative which cannot be distinguished from this is to have a P_{13} resonance with M = 1530 MeV, Γ = 79 MeV, and elasticity = +0.271.

[8] LONGACRE 77 considers this coupling to be well determined.

[9] WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

[10] Converted to our conventions using M = 1486 MeV, Γ = 613 MeV from NOELLE 78.

$N(1520)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] LONGACRE 77 considers this coupling to be well determined.

[6] Converted to our conventions using $M = 1528$ MeV, $\Gamma = 187$ MeV from NOELLE 78.

N(1535) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	35–55 %
Γ_2	$N\eta$	30–55 %
Γ_3	$N\pi\pi$	1–10 %
Γ_4	$\Delta\pi$	<1 %
Γ_5	$\Delta(1232)\pi$, D-wave	
Γ_6	$N\rho$	<4 %
Γ_7	$N\rho$, S=1/2, S-wave	
Γ_8	$N\rho$, S=3/2, D-wave	
Γ_9	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<3 %
Γ_{10}	$N(1440)\pi$	<7 %
Γ_{11}	$p\gamma$	0.45–0.53 %
Γ_{12}	$p\gamma$, helicity=1/2	
Γ_{13}	$n\gamma$	0.34–0.48 %
Γ_{14}	$n\gamma$, helicity=1/2

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1650)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] BAKER 79 fixed this coupling during fitting, but the negative sign relative to the $N(1535)$ is well determined.

[7] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions. Superseded by SAXON 80.

[8] The range given for DEANS 75 is from the four best solutions.

[9] LONGACRE 77 considers this coupling to be well determined.

N(1675) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to πN → Nππ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to πN → Nππ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] SAXON 80 finds the coupling phase is near 90°.

[6] The range given is from the four best solutions. DEANS 75 disagrees with π⁺p → Σ⁺K⁺ data of WINNIK 77 around 1920 MeV.

[7] LONGACRE 77 considers this coupling to be well determined.

[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

$N(1680)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	60–70 %
Γ_2	$N\eta$	
Γ_3	ΛK	
Γ_4	ΣK	
Γ_5	$N\pi\pi$	30–40 %
Γ_6	$\Delta\pi$	5–15 %
Γ_7	$\Delta(1232)\pi$, P-wave	6–14 %
Γ_8	$\Delta(1232)\pi$, F-wave	<2 %
Γ_9	$N\rho$	3–15 %
Γ_{10}	$N\rho$, S=1/2, F-wave	
Γ_{11}	$N\rho$, S=3/2, P-wave	<12 %
Γ_{12}	$N\rho$, S=3/2, F-wave	1–5 %
Γ_{13}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	5–20 %
Γ_{14}	$p\gamma$	0.21–0.35 %
Γ_{15}	$p\gamma$, helicity=1/2	
Γ_{16}	$p\gamma$, helicity=3/2	
Γ_{17}	$n\gamma$	0.02–0.04 %
Γ_{18}	$n\gamma$, helicity=1/2	
Γ_{19}	$n\gamma$, helicity=3/2

$N(1680)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] The parametrization used may be double counting.

[6] The range given is from 3 of 4 best solutions; not present in solution 1. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[7] LONGACRE 77 considers this coupling to be well determined.

[8] A Breit-Wigner fit to the HERNDON 75 IPWA.

$N(1700)$ D_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

The various partial-wave analyses do not agree very well.

$N(1700)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions.

$N(1710)$ P_{11}

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

The various partial-wave analyses do not agree very well.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1710)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.

[7] The range given for DEANS 75 is from the four best solutions.

N(1720) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_j/Γ)
Γ_1	$N\pi$	10–20 %
Γ_2	$N\eta$	
Γ_3	ΛK	1–15 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	>70 %
Γ_6	$\Delta\pi$	
Γ_7	$\Delta(1232)\pi$, P-wave	
Γ_8	$N\rho$	70–85 %
Γ_9	$N\rho$, S=1/2, P-wave	
Γ_{10}	$N\rho$, S=3/2, P-wave	
Γ_{11}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	
Γ_{12}	$p\gamma$	0.01–0.06 %
Γ_{13}	$p\gamma$, helicity=1/2	
Γ_{14}	$p\gamma$, helicity=3/2	
Γ_{15}	$n\gamma$	
Γ_{16}	$n\gamma$, helicity=1/2	
Γ_{17}	$n\gamma$, helicity=3/2

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1720)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] The overall phase of BAKER 78 copulings has been changed to agree with previous conventions.

[7] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

OMITTED FROM SUMMARY TABLE

There is some evidence for two resonances in this wave between 1800 and 2200 MeV (see CUTKOSKY 80). However, the solution of HOEHLER 79 is quite different.

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** (1982).

N(2080) FOOTNOTES

[1] CUTKOSKY 80 finds a lower mass D_{13} resonance, as well as one in this region. Both are listed here.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

N(2190) FOOTNOTES

[1] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

$N(2250)$ FOOTNOTES

[1] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

$N(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an $N(3245)$, an $N(3690)$, and an $N(3755)$, each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an $N(3030)$, deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 $L_{1,15}$ state below.

Δ(1232) PHASE OF M1+(3/2) PHOTOPRODUCTION MULTIPOLE AMPLITUDE POLE RESIDUE

Information on the phase (and magnitude) of the M1+(3/2) multipole amplitude pole residue is contained implicitly in the paper of MIROSHNICHENKO 79. They find that the phase is consistent with being equal to that of the elastic pole residue.

Δ(1232)$^{++}$ MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on $\pi^+ p$ bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is *only* a rough guess of the range we expect the moment to lie within.

VALUE (μ_N)	DOCUMENT ID		COMMENT
3.7 to 7.5 OUR ESTIMATE			
• • • We do not use the following data for averages, fits, limits, etc. • • •			
4.52±0.50±0.45	BOSSHARD	91	$\pi^+ p \to \pi^+ p\gamma$ (SIN data)
3.7 to 4.2	LIN	91B	$\pi^+ p \to \pi^+ p\gamma$ (from UCLA data)
4.6 to 4.9	LIN	91B	$\pi^+ p \to \pi^+ p\gamma$ (from SIN data)
5.6 to 7.5	WITTMAN	88	$\pi^+ p \to \pi^+ p\gamma$ (from UCLA data)
6.9 to 9.8	HELLER	87	$\pi^+ p \to \pi^+ p\gamma$ (from UCLA data)
4.7 to 6.7	NEFKENS	78	$\pi^+ p \to \pi^+ p\gamma$ (UCLA data)

Δ(1232) FOOTNOTES

[1] Using $\pi^\pm d$ as well, PEDRONI 78 determine $(M^- - M^{++}) + (M^0 - M^+)/3 = 4.6 \pm 0.2$ MeV.
[2] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[3] The accuracy claimed by ZIDELL 80 on the real part is considerably better than is allowed by uncertainties in the beam momentum.
[4] This VASAN 76B value is from fits to the coulomb-barrier-corrected CARTER 73 phase shift.
[5] ZIDELL 78 fits the nuclear phase shift without coulomb barrier corrections.
[6] This VASAN 76B value is from fits to the CARTER 73 nuclear phase shift without coulomb barrier corrections.
[7] Converted to our conventions using $M = 1232$ MeV, $\Gamma = 110$ MeV from NOELLE 78.

Δ(1600) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

[6] LONGACRE 77 considers this coupling to be well determined.

[7] WADA 84 is inconsistent with other analyses — see the Note on N and Δ Resonances.

Δ(1620) FOOTNOTES

[1] CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of *N* and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] LONGACRE 77 considers this coupling to be well determined.

Δ(1700) FOOTNOTES

[1] Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.
[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[6] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[7] LONGACRE 77 considers this coupling to be well determined.

Δ(1910) FOOTNOTES

[1] CHEW 80 reports four resonances in the P_{31} wave — see also the Δ(1750). Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 and HOEHLER 94 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] The range given for DEANS 75 is from the four best solutions.

[5] Evidence for this coupling is weak; see NOVOSELLER 78. This coupling assumes the mass is near 1820 MeV.

Δ(~ 3000 Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a Δ(2850) and a Δ(3230). The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The Δ(2850) has been resolved into the Δ(2750) $I_{3,13}$ and Δ(2950) $K_{3,15}$. The Δ(3230) is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

NOTE ON BARYON MAGNETIC MOMENTS

The figure shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p, n, and Λ moments as input. In this model, the moments are [1]

$$\mu_p = (4\mu_u - \mu_d)/3 \qquad \mu_n = (4\mu_d - \mu_u)/3$$
$$\mu_{\Sigma^+} = (4\mu_u - \mu_s)/3 \qquad \mu_{\Sigma^-} = (4\mu_d - \mu_s)/3$$
$$\mu_{\Xi^0} = (4\mu_s - \mu_u)/3 \qquad \mu_{\Xi^-} = (4\mu_s - \mu_d)/3$$
$$\mu_\Lambda = \mu_s \qquad \mu_{\Sigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3$$
$$\mu_{\Omega^-} = 3\mu_s$$

and the $\Sigma^0 \to \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}\,.$$

The quark moments that result from this model are $\mu_u = +1.852\,\mu_N$, $\mu_d = -0.972\,\mu_N$, and $\mu_s = -0.613\,\mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.5$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[9] CHAUVAT 85 actually gives $\alpha_+(\overline{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$. Assumes polarization is same in $\overline{p}p \to \overline{\Lambda}X$ and $pp \to \Lambda X$. Tests of this assumption, based on *C*-invariance and fragmentation, are satisfied by the data.

g_A/g_V FOR $\Lambda \to pe^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the Note on Baryon Decay Parameters in the neutron Listings. The measurements all assume that the form factor $g_2 = 0$. See also the footnote on DWORKIN 90.

[10] The tabulated result assumes the weak-magnetism coupling $w \equiv g_W(0)/g_V(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures* w to be 0.15 ± 0.30, and then $g_A/g_V = -0.731 \pm 0.016$.

[11] This experiment measures only the absolute value of g_A/g_V.

Λ REFERENCES

We have omitted some papers that have been superseded by later experiments. The omitted papers may be found in our 1986 edition (Physics Letters **170B**) or in earlier editions.

NOTE ON Λ AND Σ RESONANCES

Introduction: There are no new results at all on Λ and Σ resonances. The field remains at a standstill and will only be revived if a kaon factory is built. What follows is a much abbreviated version of the Note on Λ and Σ Resonances from our 1990 edition. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Full Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1, the amplitude for $K^-p \to \overline{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \to \Lambda\pi$ and $\overline{K}N \to \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [1] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

****	Existence is certain, and properties are at least fairly well explored.
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
**	Evidence of existence is only fair.
*	Evidence of existence is poor.

Listings, a + or − sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [2].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or

to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The $\Sigma(1385)$ and $\Lambda(1405)$ of course lie below the $\overline{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of $\Lambda(1520)$ and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the Note on the $\Sigma(1670)$.

Λ(1405) S_{01}

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ****

NOTE ON THE Λ(1405)

(by R.H. Dalitz, Oxford University)

It is generally accepted that the $\Lambda(1405)$ is a well-established $J^P = 1/2^-$ resonance. It is assigned to the lowest $L = 1$ supermultiplet of the 3-quark system and paired with the $J^P = 3/2^-$ $\Lambda(1520)$. Lying about 30 MeV below the $N\overline{K}$ threshold, the $\Lambda(1405)$ can be observed directly only as a resonance bump in the $(\Sigma\pi)^0$ subsystem in final states of production experiments. It was first reported by ALSTON 61B in the reaction $K^-p \to \Sigma\pi\pi\pi$ at 1.15 GeV/c and has since been seen in at least eight other experiments. However, only two of them had enough events for a detailed analysis: THOMAS 73, with about 400 $\Sigma^{\pm}\pi^{\mp}$ events from $\pi^-p \to K^0(\Sigma\pi)^0$ at 1.69 GeV/c; and HEMINGWAY 85, with 766 $\Sigma^+\pi^-$ and 1106 $\Sigma^-\pi^+$ events from $K^-p \to (\Sigma\pi\pi)^+\pi^-$ at 4.2 GeV/c, after the selections $1600 \leq M(\Sigma\pi\pi)^+ \leq 1720$ MeV and momentum transfer ≤ 1.0 $(\text{GeV}/c)^2$ to purify the $\Lambda(1405) \to (\Sigma\pi)^0$ sample. These experiments agree on a mass of about 1395–1400 MeV and a width of about 60 MeV. (Hemingway's mass of 1391 ± 1 MeV is from his best, but unacceptably poor, Breit-Wigner fit.)

The Byers-Fenster tests on these data allow any spin and either parity: neither J nor P has yet been determined *directly*. The early indications for $J^P = 1/2^-$ came from finding $\text{Re}\,A_{I=0}$ to be large and negative in a constant-scattering-length analysis of low-energy $N\overline{K}$ reaction data (see KIM 65, SAKITT 65, and earlier references cited therein). The first multichannel energy-dependent K-matrix analysis (KIM 67) strengthened the case for a resonance around 1400–1420 MeV strongly coupled to the $I = 0$ S-wave $N\overline{K}$ system.

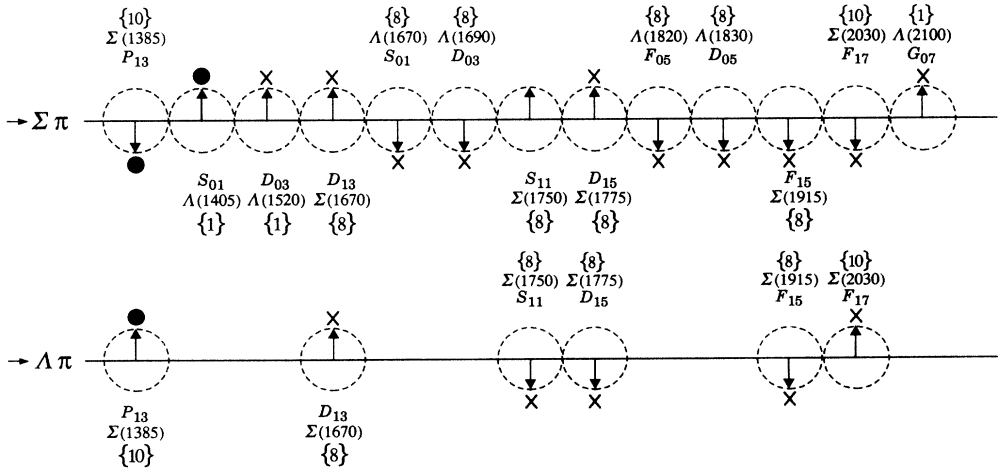

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \to \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a •, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

See key on page 1343

THOMAS 73 and HEMINGWAY 85 both found the $\Lambda(1405)$ bump to be asymmetric and not well fitted by a Breit-Wigner resonance function with constant parameters. The asymmetry involves a rapid fall in intensity as the $N\overline{K}$ threshold energy is approached from below. This is readily understood as due to a strong coupling of the $\Lambda(1405)$ to the S-wave $N\overline{K}$ channel (see DALITZ 81). This striking S-shaped cusp behavior at a new threshold is characteristic of S-wave coupling; the other below-threshold hyperon, the $\Sigma(1385)$, has no such threshold distortion because its $N\overline{K}$ coupling is P-wave. For the $\Lambda(1405)$, this asymmetry is the *sole direct evidence* that $J^P = 1/2^-$.

Following the early work cited above, a considerable literature has developed on proper procedures for phenomenological extrapolation below the $N\overline{K}$ threshold, partly in order to strengthen the evidence for the spin-parity of the $\Lambda(1405)$, and partly to provide an estimate for the amplitude $f(N\overline{K})$ in the unphysical domain below the $N\overline{K}$ threshold; the latter is needed for the evaluation of the dispersion relation for $N\overline{K}$ and NK forward scattering amplitudes. For recent reviews, see MILLER 84 and BARRETT 89. In most recent work, the $(\Sigma\pi)^0$ production spectrum is included in the data fitted (see, *e.g.*, CHAO 73, MARTIN 81).

It is now accepted that the data can be fitted only with an S-wave pole in the reaction amplitudes below $N\overline{K}$ threshold (see, however, FINK 90), but there is still controversy about the physical origin of this pole (for a review, see DALITZ 81 and DALITZ 82). Two extreme possibilities are: (a) an $L = 1$ SU(3)-singlet *uds* state coupled with the S-wave meson-baryon systems; or (b) an unstable $N\overline{K}$ bound state, analogous to the (stable) deuteron in the NN system. The problem with (a) is that the $\Lambda(1405)$ mass is so much lower than that of its partner, the $\Lambda(1520)$. This requires, in the QCD-inspired quark model, rather large spin-orbit couplings, whether or not one uses relativistic kinetic energies. ISGUR 80, CAPSTICK 86, and CAPSTICK 89 conclude that a proper QCD calculation leads only to small energy splittings, whereas LEINWEBER 90, using QCD sum rules, obtains a good fit to this splitting.

On the other hand, the problem with (b) is that then another $J^P = 1/2^-\Lambda$ is needed to replace the $\Lambda(1405)$ in the $L = 1$ supermultiplet, and it would have to lie close to the $\Lambda(1520)$, a region already well explored by $N\overline{K}$ experiments without result. Intermediate structures are possible; for example, the cloudy bag model allows the configurations (a) and (b) to mix and finds the intensity of (a) in the $\Lambda(1405)$ to be only 14% (VEIT 84, VEIT 85, JENNINGS 86). Such models naturally predict a second $1/2^-$ Λ close to the $\Lambda(1520)$.

The determination of the mass and width of the resonance from $(\Sigma\pi)^0$ data is usually based on the "Watson approximation," which states that the production rate $R(\Sigma\pi)$ of the $(\Sigma\pi)^0$ state has a mass dependence proportional to $(\sin^2\delta_{\Sigma\pi})/q$, q being the $\Sigma\pi$ c.m. momentum, in a $\Sigma\pi$ mass range where $\delta_{\Sigma\pi}$ is not far from $\pi/2$ and only the $\Sigma\pi$ channel is open, *i.e.*, between the $\Sigma\pi$ and the $N\overline{K}$ thresholds. Then $q\,R(\Sigma\pi)$ is proportional to $\sin^2\delta_{\Sigma\pi}$, and the mass M may be defined as the energy at which $\sin^2\delta_{\Sigma\pi} = 1$. The width Γ may be determined from the rate at which $\delta_{\Sigma\pi}$ goes through $\pi/2$, or from the FWHM; this is a matter of convention.

This determination of M and Γ from the data suffers from the following defects:

(i) The determination of $\sin^2\delta_{\Sigma\pi}$ requires that $R(\Sigma\pi)$ be scaled to give $\sin^2\delta_{\Sigma\pi} = 1$ at the peak for the best fit to the data; *i.e.*, the bump must be *assumed* to arise from a resonance. However, this assumption is supported by the analysis of the low-energy $N\overline{K}$ data and its extrapolation below threshold.

(ii) Owing to the nearby $N\overline{K}$ threshold, the shape of the best fit to the $M(\Sigma\pi)$ bump is uncertain. For energies below this threshold at $E_{N\overline{K}}$, the general form for $\delta_{\Sigma\pi}$ is

$$q\cot\delta_{\Sigma\pi} = \frac{1+\kappa\alpha}{\gamma+\kappa(\alpha\gamma-\beta^2)}\ .$$

Here α, β, and γ are the (generally energy-dependent) NN, $N\Sigma$, and $\Sigma\Sigma$ elements of the $I = 0$ S-wave K-matrix for the $(\Sigma\pi, N\overline{K})$ system, and κ is the magnitude of the (imaginary) c.m. momentum k_K for the $N\overline{K}$ system below threshold. The elements α, β, γ are real functions of E; they have no branch cuts at the $\Sigma\pi$ and $N\overline{K}$ thresholds, but they are permitted to have poles in E along the real E axis. The resonance asymmetry arises from the effect of κ on $\delta_{\Sigma\pi}$. We note that $\delta_{\Sigma\pi} = \pi/2$ when $\kappa = -1/\alpha$.

Accepting this close connection of $\delta_{\Sigma\pi}$ with the low-energy $N\overline{K}$ data, it is natural to analyze the two sets of data together (*e.g.*, MARTIN 81), and there is now a large body of accurate $N\overline{K}$ data for laboratory momenta between 100 and 300 MeV/c (see MILLER 84). The two sets of data span c.m. energies from 1370 MeV to 1490 MeV, and the K-matrix elements will not be energy independent over such a broad range. For the $I = 0$ channels, a linear energy dependence for K^{-1} has been adopted routinely ever since the work of KIM 67, and it is essential when fitting the $q\,R(\Sigma\pi)$ and $N\overline{K}$ data together. However, $q\,R(\Sigma\pi)$ is not always well fitted in this procedure; the value obtained for the $\Lambda(1405)$ mass M varies a good deal with the type of fit, not a surprising result when the $\Sigma\pi$ mass spectrum contributes only nine data points in a total of about 200. The value of M obtained from an overall fit is not necessarily much better than from one using only the $q\,R(\Sigma\pi)$ data; and M may be a function of the representation— K-matrix, K^{-1}-matrix, relativistic-separable or nonseparable potentials, *etc.*— used in fitting over the full energy range. DALITZ 90 fitted the $qR(\Sigma^+\pi^-)$ Hemingway data with each of the first three representations just mentioned, constrained to the $I = 0$ $N\overline{K}$ threshold scattering length from low-energy $N\overline{K}$ data. The (nonseparable) meson-exchange potentials of MÜLLER-GROELING 90, fitted to the low-energy $N\overline{K}$ (and NK) data, predicted an unstable $N\overline{K}$ bound state with mass and width compatible with the $\Lambda(1405)$.

The present status of the $\Lambda(1405)$ thus depends heavily on theoretical arguments, a somewhat unsatisfactory basis for a four-star rating. Nevertheless, there is no known reason to

Baryon Full Listings

$\Lambda(1405)$

doubt its existence or quantum numbers. A measurement of the energy-level shifts and widths for the atomic levels of kaonic hydrogen (and deuterium) would give a valuable check on analyses of the $(\Sigma\pi, N\overline{K})$ amplitudes, since the energy of the K^-p atom lies roughly midway between those for the two sets of data. The three measurements of $(\Delta E - i\Gamma/2)$ for kaonic hydrogen are inconsistent with one another and require that the sign of $\mathrm{Re}(A_{I=0} + A_{I=1})$ be opposite that deduced from $N\overline{K}$ reaction data (see BATTY 89). Accurate measurements of $(\Delta E - i\Gamma/2)$ values for kaonic hydrogen are badly needed, but may not be possible until the KAON factory becomes operational.

To definitively settle the nature of the $\Lambda(1405)$ will require much further work, both experimental and theoretical. Higher-statistics experiments on the production and decay of the $\Lambda(1405)$ are needed, but suitable K^- beams will not be available until KAON. The low-energy reaction cross sections, especially for the $\overline{K}^0p$ interactions, last studied 25 years ago, need to be better determined.

Λ(1520) D_{03}

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ****

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** (1982).

Production and formation experiments agree quite well, so they are listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 24 measurements and one constraint to determine 6 parameters. The overall fit has a χ^2 = 16.5 for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−63				
x_3	−32	−33			
x_7	−4	−3	−1		
x_8	−9	−8	−4	0	
x_9	−24	−21	−10	−1	−2
	x_1	x_2	x_3	x_7	x_8

0.041±0.005	CHAN	72	HBC	$K^-p \to \Lambda\pi\pi$

$\Gamma(\Sigma(1385)\pi(\to \Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$ Γ_5/Γ_3

The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$. Only the values of $(\Sigma(1385)\pi)$ / $(\Lambda 2\pi)$ given by MAST 73B and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{S\text{-wave}}$ state.

Λ(1520) FOOTNOTES

[1] From the best-resolution sample of $\Lambda\pi\pi$ events only.
[2] The $\overline{K}N \to \Sigma\pi$ amplitude at resonance is +0.46 ± 0.01.
[3] Assumes $\Gamma(N\overline{K})/\Gamma_{total} = 0.46 \pm 0.02$.
[4] Both $\Sigma(1385)\pi$ DS_{03} and $\Sigma(\pi\pi)$ DP_{03} contribute.
[5] The central bin (1514–1524 MeV) gives 0.74 ± 0.10; other bins are lower by 2-to-5 standard deviations.
[6] Much of the $\Sigma\pi\pi$ decay proceeds via $\Sigma(1385)\pi$.
[7] Assumes $\Gamma(N\overline{K})/\Gamma_{total} = 0.46$.
[8] Calculated from $\Gamma(\Lambda\gamma)/\Gamma_{total}$, assuming SU(3). Needed to constrain the sum of all the branching ratios to be unity.

Λ(1690) DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	20–30 %
Γ_2	$\Sigma\pi$	20–40 %
Γ_3	$\Lambda\pi\pi$	~ 25 %
Γ_4	$\Sigma\pi\pi$	~ 20 %
Γ_5	$\Lambda\eta$	
Γ_6	$\Sigma(1385)\pi$, S-wave	

The above branching fractions are our estimates, not fits or averages.

Λ(1690) BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

Λ(1690) FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another D_{03} Λ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

[2] BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

$\Lambda(1820)\ F_{05}$

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ****

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

Λ(1820) FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \to \Sigma\pi$ decay.
[3] The published sign has been changed to be in accord with the baryon-first convention.

Λ(1890) P_{03}

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ****

For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

The $J^P = 3/2^+$ assignment is consistent with all available data (including polarization) and recent partial-wave analyses. The dominant inelastic modes remain unknown.

Λ(2000)

$I(J^P) = 0(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5, P_3+D_5, or P_1+D_3 (BRANDSTETTER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\overline{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

Λ(2020) F_{07}

$I(J^P) = 0(\frac{7}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new $K^- n$ angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

Λ(2325) D_{03}

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^- p \rightarrow \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^- p \rightarrow \overline{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

[a] See the Full Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 7.5 for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−100		
x_3	9	−11	
	x_1	x_2

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0-Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2\,\tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

VALUE (10^{-20} s)	DOCUMENT ID		TECN	COMMENT
7.4±0.7 OUR EVALUATION Using $\mu_{\Sigma\Lambda}$ (see the above note).

[a] See the Full Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 8.7 for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

g_A/g_V FOR $\Sigma^- \to ne^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the Note on Baryon Decay Parameters in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237 g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

0.17 $^{+0.07}_{-0.09}$	519	DECAMP	77	ELEC	Hyperon beam

[6] The sign is, *with our conventions*, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

[7] BOURQUIN 83C favors the positive sign by at least 2.6 standard deviations.

[8] TANENBAUM 74 gives 0.435 ± 0.035, assuming no q^2 dependence in g_A and g_V. The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \to ne^-\overline{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the Note on Baryon Decay Parameters in the neutron Listings.

NOTE ON $\Sigma^- \to \Lambda e^-\overline{\nu}_e$ DECAY

The vector part of the hadronic amplitude for the decay $\Sigma^- \to \Lambda e^-\overline{\nu}_e$ is of special interest because the vector weak current is proportional to an isospin rotation of the isovector part of the electromagnetic current. This strong form of CVC predicts that

$$f_1(q^2) = 0 \quad \text{for} \quad 0 < q^2 \leq (m_{\Sigma^-} - m_\Lambda)^2 \,,$$

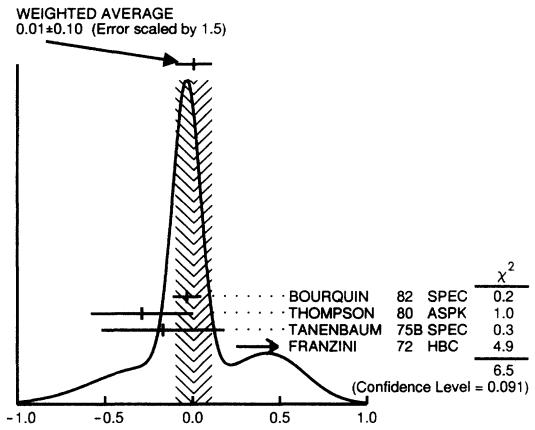
and also relates $f_2(0)$ to the $\Sigma^0\Lambda$ transition magnetic moment or to the amplitude for the decay $\Sigma^0 \to \Lambda\gamma$ by

$$\begin{aligned} f_2(0) &= -\sqrt{2}\, \mu_{\Sigma^0\Lambda}/e\hbar \\ &= -\sqrt{3/2}\, \mu_n/e\hbar \qquad \text{[by SU(3)]} \\ &= 1.17\, m_p^{-1} \,. \end{aligned}$$

No SU(3) symmetry is assumed here except in the relation of $\mu_{\Sigma^0\Lambda}$ to the magnetic moment of the neutron, μ_n.

The experimental data were analyzed on the assumption that $f_1(q^2) = 0$ and $f_2(q^2) = f_2(0)$ over the entire kinematical range of q^2 for $\Sigma^- \to \Lambda e^-\overline{\nu}_e$. The results are listed in the ratio of $g_{WM} = -m_{\Sigma^-} f_2(0)$ to $g_A = g_1(0)$.

See also the Note on Baryon Decay Parameters in the neutron section of the Full Listings.



g_V/g_A FOR $\Sigma^- \to \Lambda e^-\overline{\nu}_e$

For the sign convention, see the Note on Baryon Decay Parameters in the neutron Listings. The value is predicted to be zero by conserved vector current theory. The values averaged assume CVC-SU(3) weak magnetism term.

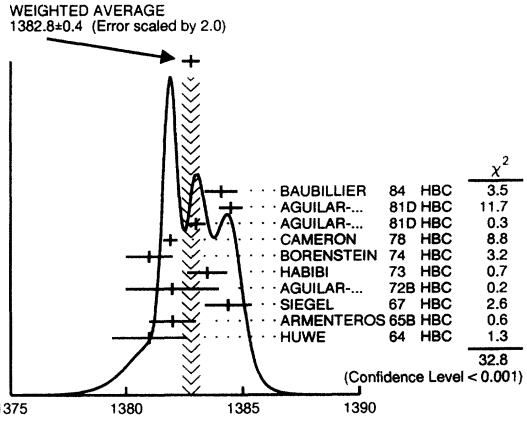
$\Sigma(1385)\ P_{13}$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ****



Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** No. 2 Pt. II (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P-wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

$\Sigma(1480)$ Bumps

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+ p \rightarrow (Y\pi)K^+$ at 1.7 GeV/c. Also, the Y polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \rightarrow \Lambda K$ decay. However, such an explanation for the $(\Sigma^+\pi^0)K^+$ channel in terms of $\Delta(1650) \rightarrow \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^- p \rightarrow \Lambda\pi^0$.

ENGELEN 80 performs a multichannel analysis of $K^- p \rightarrow p\overline{K}^0\pi^-$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in $p\overline{K}^0$ which cannot be explained as a reflection of any competing channel.

$\Sigma(1560)$ Bumps

$I(J^P) = 1(?^?)$ Status: **

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^- p \rightarrow (\Lambda/\Sigma)\pi K\overline{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^\pm$ from the reaction $pp \rightarrow \Lambda\pi^+\pi^- X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\overline{K}N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$\Sigma(1580)$ FOOTNOTES

[1] CARROLL 76 sees a total-cross-section bump with $(J+1/2)\ \Gamma_{el}\ /\ \Gamma_{total} = 0.06$.

[2] The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\overline{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

OMITTED FROM SUMMARY TABLE

The S_{11} state at 1697 MeV reported by VANHORN 75 is tentatively listed under the $\Sigma(1750)$. CARROLL 76 sees two bumps in the isospin-1 total cross section near this mass.

Production experiments are listed separately in the next entry.

Σ(1620) Production Experiments

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the previous entry.

The results of CRENNELL 69B at 3.9 GeV/c are not confirmed by SABRE 70 at 3.0 GeV/c. However, at 4.5 GeV/c, AMMANN 70 sees a peak at 1642 MeV which on the basis of branching ratios they do not associate with the Σ(1670). See MILLER 70 for a review of these conflicts.

NOTE ON THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma\pi/\Sigma\pi\pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^-p \to \pi^-\Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma\pi\pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma\pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13}. There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda\pi/\Sigma\pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

$\Sigma(1670)$ D_{13}

$I(J^P) = 1(\frac{3}{2}^-)$ Status: ****

0.081±0.016	[6] CAMERON 77	DPWA	P-wave decay

$\Sigma(1670)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] Results are with and without an S_{11} $\Sigma(1620)$ in the fit.
[3] SIMS 68 uses only cross-section data. Result used as upper limit only.
[4] Ratio only for $\Sigma 2\pi$ system in $I = 1$, which cannot be $\Sigma(1385)$.
[5] Assuming the $\Lambda(1405)\pi$ cross-section bump is due only to $3/2^-$ resonance.
[6] The CAMERON 77 upper limit on F-wave decay is 0.03.

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to $\Sigma\pi$ and $\Lambda\pi$, the other to $\Lambda(1405)\pi$. See the note in front of the preceding entry.

Σ(1690) FOOTNOTES (PRODUCTION EXPERIMENTS)

[1] From $\pi^+ p \to (\Lambda\pi^+)K^+$. $J > 1/2$ is not required by the data.
[2] From $\pi^+ p \to (\Lambda\pi^+)(K\pi)^+$. $J > 1/2$ is indicated, but large background precludes a definite conclusion.
[3] See the Σ(1670) Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the Σ(1690).
[4] This analysis, which is difficult and requires several assumptions and shows no unambiguous Σ(1690) signal, suggests $J^P = 5/2^+$. Such a state would lead all previously known Y^* trajectories.

Σ(1750) S_{11}

$I(J^P) = 1(\frac{1}{2}^-)$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\overline{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74).

$\Sigma(1770)$ FOOTNOTES

[1] Required to fit the isospin-1 total cross section of CARROLL 76 in the $\overline{K}N$ channel. The addition of new K^-p polarization and K^-n differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660)\ P_{11}$.

[2] From solution 1 of BAILLON 75; not present in solution 2.

[3] Not required in KANE 74, which supersedes KANE 72.

$\Sigma(1775)\ D_{15}$

$I(J^P) = 1(\frac{5}{2}^-)$ Status: ****

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820)$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

$\Sigma(1775)$ DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	37–43%
Γ_2	$\Lambda\pi$	14–20%
Γ_3	$\Sigma\pi$	2–5%
Γ_4	$\Sigma(1385)\pi$	8–12%
Γ_5	$\Sigma(1385)\pi$, D-wave	
Γ_6	$\Lambda(1520)\pi$	17–23%
Γ_7	$\Sigma\pi\pi$	

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 63.9$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−30			
x_3	−17	−21		
x_4	−37	−49	−14	
x_6	−81	6	8	16
	x_1	x_2	x_3	x_4

$\Sigma(1775)$ BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too small.

$\Sigma(1775)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.

[2] This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014. The published signs have been changed here to be in accord with the baryon-first convention.

[3] The CAMERON 78 upper limit on G-wave decay is 0.03.

[4] For about 3/4 of this, the $\Sigma\pi$ system has $I = 0$ and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has $I = 1$, which is about what is expected from the known $\Sigma(1775) \to \Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

$\Sigma(1915)$ F_{15}

$I(J^P) = 1(\frac{5}{2}^+)$ Status: ****

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in in a separate entry immediately following. They may be found in our 1986 edition Physics Letters **170B** (1986).

$\Sigma(1915)$ FOOTNOTES

[1] The two entries for CORDEN 77C are from two different acceptable solutions.
[2] Preferred solution 3; see CORDEN 76 for other possibilities.
[3] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[4] The mass and width are fixed to the GOPAL 77 values due to the low elasticity.
[5] The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(1940)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] The published sign has been changed to be in accord with the baryon-first convention.
[3] Upper limits on the D_1 and D_3 waves are each 0.03.

Σ(2030) F_{17}

$I(J^P) = 1(\frac{7}{2}^+)$ Status: ****

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics **56** No. 2 Pt. II (1984).

$\Sigma(2030)$ FOOTNOTES

[1] Preferred solution 3; see CORDEN 76 for other possibilities.
[2] The two entries for CORDEN 77C are from two different acceptable solutions.
[3] This coupling is extracted from unnormalized data.
[4] The published sign has been changed to be in accord with the baryon-first convention.
[5] An upper limit.
[6] The upper limit on the G_3 wave is 0.03.

$\Sigma(2070)$ F_{15}

$I(J^P) = 1(\frac{5}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new K^-p polarization and K^-n angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of $\overline{K}N \to \Sigma\pi$.

$\Sigma(2250)$

$I(J^P) = 1(?^?)$ Status: ***

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \to \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \to Y^{*+}\pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 2 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 0.0 for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Ξ^-

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ****

The parity has not actually been measured, but + is of course expected.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1986 edition (Physics Letters **170B**) or in earlier editions.

Ξ^- MASS

The fit uses the Ξ^-, $\overline{\Xi}^+$, and Ξ^0 mass and mass difference measurements. It assumes the Ξ^- and $\overline{\Xi}^+$ masses are the same.

α FOR $\Xi^- \to \Lambda\pi^-$

The above average, $\alpha(\Xi^-)\,\alpha_-(\Lambda) = -0.293 \pm 0.007$, where the error includes a scale factor of 1.8, divided by our current average $\alpha_-(\Lambda) = 0.642 \pm 0.013$, gives the following value for $\alpha(\Xi^-)$.

VALUE	DOCUMENT ID	
−0.456±0.014 OUR EVALUATION	Error includes scale factor of 1.8.	

ϕ ANGLE FOR $\Xi^- \to \Lambda\pi^-$ ($\tan\phi = \beta/\gamma$)

Review of FNAL hyperon experiments.

NOTE ON Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in recent years have electronic experiments made significant contributions. However, there is nothing new at all on Ξ resonances since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Reference

1. B.T. Meadows, in *Proceedings of the IVth International Conference on Baryon Resonances* (Toronto, 1980), ed. N. Isgur, p. 283.

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	$L_{2I\cdot 2J}$	Overall status	Status as seen in — $\Xi\pi$	ΛK	ΣK	$\Xi(1530)\pi$	Other channels
$\Xi(1318)$	P_{11}	****					Decays weakly
$\Xi(1530)$	P_{13}	****	****				
$\Xi(1620)$		*	*				
$\Xi(1690)$		***		***	**		
$\Xi(1820)$	D_{13}	***	**	***	**	**	
$\Xi(1950)$		***	**	**		*	
$\Xi(2030)$	1	***		**	***		
$\Xi(2120)$		*		*			
$\Xi(2250)$		**					3-body decays
$\Xi(2370)$	1	**					3-body decays
$\Xi(2500)$		*		*	*		3-body decays

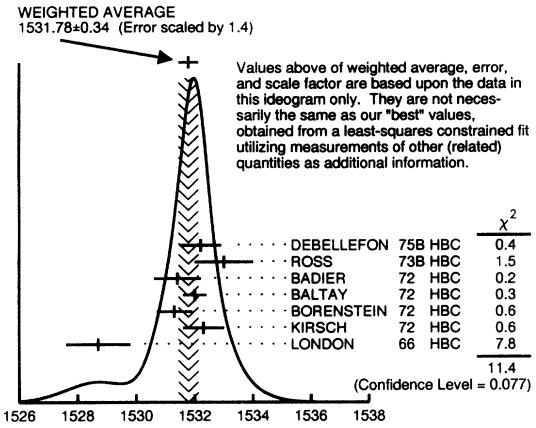
****	Existence is certain, and properties are at least fairly well explored.
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
**	Evidence of existence is only fair.
*	Evidence of existence is poor.

Baryon Full Listings

Ξ(1530)

Ξ(1530) P_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ****



This is the only Ξ resonance whose properties are all reasonably well known. Spin-parity $3/2^+$ is favored by the data.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma\overline{K}$ mass spectra in $K^-p \to (\Sigma\overline{K})K\pi$ at 4.2 GeV/c. The data from the $\Sigma\overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda\overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ.

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda\overline{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0\overline{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^-. The significance claimed is 6.7 standard deviations.

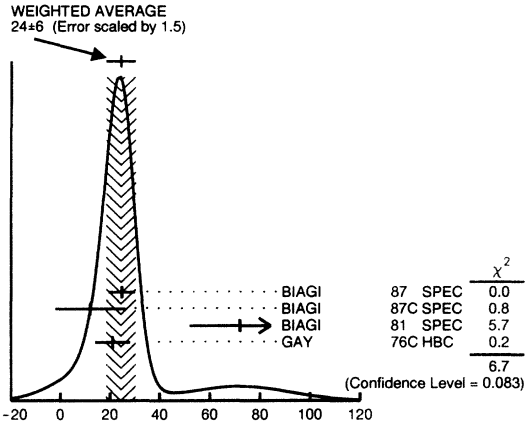
Ξ(1820)

Ξ(1820) D_{13}

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76. TEODORO 78 favors J=3/2, but cannot make a parity discrimination. BIAGI 87C is consistent with J=3/2 and favors negative parity for this J value.



Ξ(1820) MASS

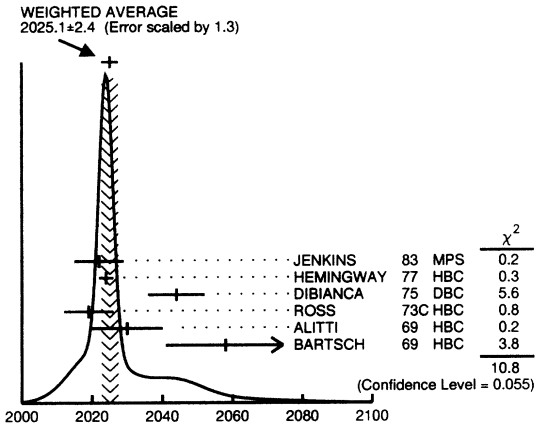
Ξ(2030)

$I(J^P) = \frac{1}{2}(\geq \frac{5}{2}^?)$ Status: ***

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma\bar{K}$ and a weaker coupling to $\Lambda\bar{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the Ξππ (or Ξ(1530)π) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma)\bar{K}\pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.



A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

Ξ(2120) FOOTNOTES

[1] CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\overline{\Lambda}K^+)$ X final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.

[2] GAY 76C sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the Ξ(2120) is real.

OMITTED FROM SUMMARY TABLE

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in $\Lambda\overline{K}\pi$, $\Sigma\overline{K}\pi$, and $\Xi\pi\pi$ mass spectra. GOLDWASSER 70 sees a narrower bump in $\Xi\pi\pi$ at a higher mass. Not seen by HASSALL 81 with 45 events/μb at 6.5 GeV/c. Seen by JENKINS 83. Perhaps seen by BIAGI 87.

Ω BARYONS ($S = -3$, $I = 0$)

$\Omega^- = sss$

Ω^-

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ****

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers have not actually been measured, but follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1986 edition (Physics Letters **170B**) or in earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same.

1670.6 ± 1.0	1	[2] FRY	55B	EMUL	
1615	1	[4] EISENBERG	54	EMUL	

[1] DIBIANCA 75 gives a mass for each event. We quote the average.

[2] The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.

[3] Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.

[4] The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^- \Xi$ Ag.

$\overline{\Omega}^+$ MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same.

OMITTED FROM SUMMARY TABLE

A peak in the $\Omega^-\pi^+\pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS ($C = +1$)

$\Lambda_c^+ = udc$, $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$, $\Sigma_c^0 = ddc$,
$\Xi_c^+ = usc$, $\Xi_c^0 = dsc$, $\Omega_c^0 = ssc$

NOTE ON CHARMED BARYONS

Figs. 1(a) and 1(b) show the SU(4) multiplets that have as their "ground floors" (a) the SU(3) octet that contains the nucleon, and (b) the SU(3) decuplet that contains the $\Delta(1232)$. All the particles in a given SU(4) multiplet have the same spin and parity. The only charmed baryons that have been discovered each contain one charmed quark and belong to the first floor of the multiplet shown in Fig. 1(a). Fig. 2 shows this first floor, pulled apart into two SU(3) multiplets, a $\overline{\mathbf{3}}$ that contains the $\Lambda_c(2285)$ and the $\Xi_c(2470)$, both of which decay weakly, and a **6** that contains the $\Sigma_c(2455)$, which decays strongly to $\Lambda_c\pi$, and the $\Omega_c(2710)$, which decays weakly (and which needs confirmation before it can be considered to be established). A second Ξ_c remains to be discovered to fill out the **6**, and a host of other baryons with one or more charmed quarks are needed to fill out the full SU(4) multiplets in Fig. 1. Furthermore, *every* N or Δ baryon resonance "starts" a multiplet like that in Fig. 1(a) or 1(b), so the woods are full of charmed baryons, most of which no doubt will forever remain undiscovered.

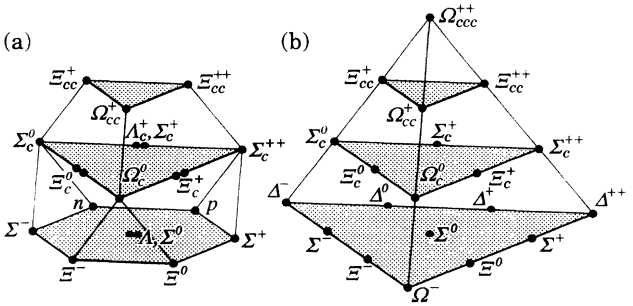

Fig. 1. SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet on the "ground floor." (b) The 20-plet with an SU(3) decuplet on the ground floor.

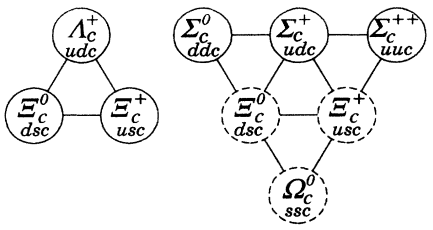

Fig. 2. The SU(3) multiplets on the "first floor" of the SU(4) multiplet of Fig. 1(a). The particles in dashed circles have yet to be discovered.

The states of the $\overline{3}$ multiplet are antisymmetric under interchange of the two light quarks (the u, d, and s quarks), and the states of the **6** multiplet are symmetric under interchange of these quarks. Actually, there may be some mixing between the pure $\overline{3}$ and **6** Ξ_c states (they have the same I, J, and P quantum numbers) to form the physical Ξ_c states.

It need hardly be said that the flavor symmetries Fig. 1 displays are very badly broken, but the figure is the simplest way to see what charmed baryons should exist.

For an entry into the literature on models of charmed baryons, see Ref. 1. For a review of recent experimental results, see Ref. 2. For a review of both theory and experiment, see Ref. 3.

Λ_c^+

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

J has not actually been measured yet. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with the expected $J = 1/2$. The quark content is udc.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1992 edition (Physical Review **D45**, 1 June, Part II) or in earlier editions.

Λ_c^+ MASS

Measurements with an error greater than 5 MeV or that are otherwise obsolete have been omitted.

The fit also uses $(m_{\Sigma_c} - m_{\Lambda_c^+})$ measurements.

[a] The branching fraction includes all the decay modes of the final-state resonance.

[b] The value is for the sum of the charge states indicated.

Baryon Full Listings

Λ_c^+

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 14 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 12.8$ for 10 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

>0.044	90	6	[5] AGUILAR-...	88B	LEBC	pp 27.4 GeV
0.022 ±0.010		39	ABRAMS	80	MRK2	e^+e^- 5.2 GeV

[1] BERGFELD 94 measures $\Gamma(pK^-\pi^+)/\Gamma(\Lambda\ell^+\nu_\ell) = 1.93 \pm 0.10 \pm 0.33$ and calculates $\Gamma(e^+\text{anything})/\Gamma_{total} = 0.034 \pm 0.004$ from D-meson data, assuming that all charmed hadrons have the same semileptonic width. Combined, these values give $\Gamma(pK^-\pi^+)/\Gamma_{total} = f \times (6.67 \pm 0.35 \pm 1.35)\%$, where $f \equiv \Gamma(\Lambda\ell^+\nu_\ell)/\Gamma(\ell^+\text{anything})$. Since $f \leq 1$, this gives an upper bound on $\Gamma(pK^-\pi^+)/\Gamma_{total}$. In the spectator model, the quantity corresponding to f in D-meson decay is $\Gamma(D \to (\overline{K}+\overline{K}^*)\ell^+\nu_\ell)/\Gamma(D \to \ell^+\text{anything}) = 0.89 \pm 0.12$. This value of f leads to the value of $\Gamma(pK^-\pi^+)/\Gamma_{total}$ we give here.

[2] ALBRECHT 92O uses $B(\overline{B} \to \Lambda_c^+ X) \times B(\Lambda_c^+ \to pK^-\pi^+) = (0.28 \pm 0.05)\%$ plus $B(\overline{B} \to \Lambda_c^+ X) = (6.8 \pm 0.5 \pm 0.3)\%$ and assumes that $\overline{B} \to \Xi_c X$ and $\overline{B} \to \Omega_c X$ decays are suppressed and negligible.

[3] CRAWFORD 92 $B(\overline{B} \to \Lambda_c^+ X) \times B(\Lambda_c^+ \to pK^-\pi^+) = (0.273 \pm 0.051 \pm 0.039)\%$ and estimates $B(\overline{B} \to \Lambda_c^+ X) = (6.4 \pm 0.8 \pm 0.8)\%$. If final states other than $\Lambda_c^+ \overline{N} X$ contribute to $\overline{B}$ decay, the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction would increase.

[4] ALBRECHT 88E use their result $B(\overline{B} \to \Lambda_c^+ X) \times B(\Lambda_c^+ \to pK^-\pi^+) = (0.30 \pm 0.12 \pm 0.06)\%$ plus $B(\overline{B} \to \Lambda_c^+ X) = (7.4 \pm 2.9)\%$ from other measurements of inclusive proton and Λ yields in B decays.

[5] This AGUILAR-BENITEZ 88B limit assumes that $\tau_{\Lambda_c} = 1.2 \times 10^{-13}$ s, and it "decreases by 20% [to > 0.035] assuming a lifetime of 1.7×10^{-13} s instead." Our average for τ_{Λ_c} is still higher (see the mean-life section), which would further reduce the limit.

$\Gamma(p\overline{K}^*(892)^0)/\Gamma(pK^-\pi^+)$ Γ_3/Γ_2

Unseen decay modes of the $\overline{K}^*(892)^0$ are included.

$\Lambda_c(2625)^+$ $I = 0$ Status: ***

This could be a $\Sigma_c(2625)^+$ instead of a $\Lambda_c(2625)^+$, but theoretical estimates of the masses of excited charmed baryons are much more in accord with it being a Λ_c^+.

Baryon Full Listings

Ξ_c^+, Ξ_c^0

Ξ_c^+

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P have actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

2460 ±25	82	BIAGI	83	SPEC	Σ^- Be 135 GeV

[1] Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \to \Sigma^0 K^-\pi^+\pi^+ \to (\Lambda\gamma)K^-\pi^+\pi^+$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

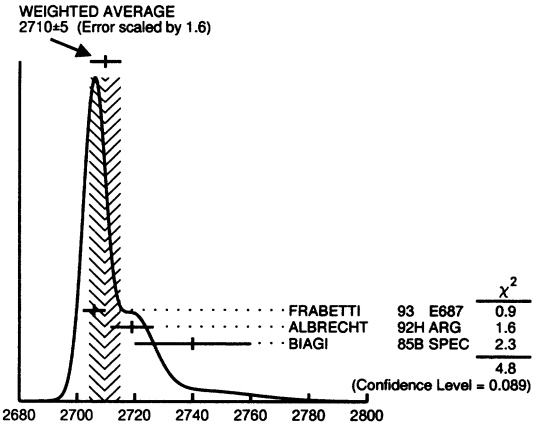
Ω_c^0

$I(J^P) = 0(\frac{1}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

The quantum numbers have not been measured, but are simply assigned in accord with the quark model, in which the Ω_c^0 is the *ssc* ground state.



BIAGI 85B and ALBRECHT 92H see bumps in the $\Xi^- K^-\pi^+\pi^+$ mass spectrum. FRABETTI 93 sees a bump in the $\Omega^-\pi^+$ spectrum but not in the $\Xi^- K^-\pi^+\pi^+$ spectrum. Perhaps all the experiments are seeing the Ω_c^0, but statistics are low and further confirmation is desired.

Ω_c^0 MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
2710 ± 5 OUR AVERAGE		Error includes scale factor of 1.6. See the ideogram below.

BOTTOM (BEAUTY) BARYON ($B = -1$)

$\Lambda_b^0 = udb$

Λ_b^0

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ***

In the quark model, a Λ_b^0 is an isospin-0 udb state. The lowest Λ_b^0 ought to have $J^P = 1/2^+$. None of I, J, or P have actually been measured.

Λ_b^0 MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
5641± 50 OUR AVERAGE

5425^{+175}_{-75}		[4] BASILE	81	SFM	See BARI 91

[1] ALBAJAR 91E claims 16 ± 5 events above a background of 9 ± 1 events, a significance of about 5 standard deviations.

[2] ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30 ± 23 $\Lambda_b^0 \to J/\psi(1S)\Lambda$ events. Instead, CDF found not more than 2 events.

[3] The decay of the Λ_b^0 to the final state observed by ARENTON 86 is Cabibbo suppressed, whereas the decay of a Ξ_b^0 to this final state is allowed. ARENTON 86 thus only claims to have observed a baryon which probably has a b quark and has a D^0 among the decay products, not necessarily the Λ_b^0.

[4] The first claim to have discovered the Λ_b^0 was reported by BASILE 81. In contrast, DRIJARD 82 reported no observation of Λ_b^0, and this led to some discussion in BASILE 82 and DRIJARD 82B. Further evidence for the Λ_b^0 was again reported by the first authors in BARI 91 (see above) in a second, upgraded experiment where two different Λ_b^0 decay modes were observed.

Λ_b^0 MEAN LIFE

These are actually measurements of the average lifetime of weakly decaying b baryons weighted by generally unknown production rates, branching fractions, and detection efficiencies. Presumably, the mix is mainly Λ_b^0, with some Ξ_b^0 and Ξ_b^-.

SEARCHES FOR FREE QUARKS, MONOPOLES, SUPERSYMMETRY, COMPOSITENESS, etc.

Free Quark Searches

NOTE ON QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to "unglue" quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–3.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

(a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
(b) is the probability of fractional charge on nuclear fragments.
(c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
(d) is quarks per collision.
(e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^- \to \mu^+\mu^-)$.
(f) is quark flux per charged particle.
(g) is the flux per ν-event.
(h) is quark yield per π^- yield.
(i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^- \to \mu^+\mu^-)$.

[21] Distribution in celestial sphere was described as anisotropic.
[22] With telescope axis at zenith angle 40° to the south.
[23] Leptonic quarks.
[24] Lifetime $> 10^{-8}$ s; charge ±0.70, 0.68, 0.42; and mass >4.4, 4.8, and 20 GeV, respectively.
[25] Time delayed air shower search.
[26] Prompt air shower search.
[27] Also $e/4$ and $e/6$ charges.
[28] No events in subsequent experiments.

Quark Density — Matter Searches

For a recent review, see SMITH 89.

[29] Also set limits for $Q = \pm e/6$.
[30] Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.
[31] Limit inferred by JONES 77B.

Magnetic Monopole Searches

NOTE ON MAGNETIC MONOPOLE SEARCHES

(by W.P. Trower, Virginia Polytechnic Institute and State University)

Although the usual formulation of Maxwell's equations suggests magnetic monopoles, no observed phenomenon requires them for explanation [1]. A monopole anywhere in the universe results in electric charge quantization everywhere, and leads to the prediction of a least magnetic charge $G = e/2\alpha$, the Dirac charge [2]. Recently monopoles have become indispensable in many gauge theories, which endow them with a variety of extraordinarily large masses.

Monopole detectors have predominantly used either induction or ionization. Induction experiments measure the monopole magnetic charge and are independent of monopole electric charge, mass, and velocity. Monopole candidate events (CABRERA 82, CAPLIN 86) in single semiconductor loops have been detected by this method, but no two-loop coincidence has been observed. Ionization experiments rely on a magnetic charge producing more ionization than an electrical charge with the same velocity. However, the ability to distinguish a monopole by ionization diminishes with velocity.

Cosmic rays are the most likely source of massive monopoles, since accelerator energies are insufficient to produce them. Evidence for such monopoles may also be obtained from astrophysical observations.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative.

Supersymmetric Particle Searches

NOTE ON SUPERSYMMETRY

(by Howard E. Haber, Univ. of California, Santa Cruz)

Supersymmetry is an attractive theoretical framework that may permit the consistent unification of particle physics and gravity, which takes place at an energy of order the Planck scale ($\approx 10^{19}$ GeV) [1–3]. However, supersymmetry is clearly not an exact symmetry of nature, and therefore must be broken. In theories of "low-energy" supersymmetry, the effective scale of supersymmetry breaking is tied to the electroweak scale [4,5]. In this way, it is hoped that supersymmetry will ultimately explain the origin of the large hierarchy between the W and Z masses and the Planck scale.

The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the Standard Model and adding the corresponding supersymmetric partners [6]. In addition, the MSSM contains two hypercharge $Y = \pm 1$ Higgs doublets, which is the minimal structure for the Higgs sector of an anomaly-free supersymmetric extension of the Standard Model that generates mass for both "up"-type and "down"-type quarks (and charged leptons) [7,8]. Supersymmetric interactions consistent with (global) B–L conservation (B =baryon number and L =lepton number) are included. Finally, the most general soft-supersymmetry-breaking terms are added [9]. If supersymmetry is relevant for explaining the scale of electroweak interactions, then the mass parameters that occur in the soft-supersymmetry-breaking terms must be of order 1 TeV or below [10]. Some bounds on these parameters exist due to the absence of supersymmetry particle production at current accelerators, as well as the absence of any evidence for virtual supersymmetric particle exchange in a variety of Standard Model processes [11].

As a consequence of B–L invariance, the MSSM possesses a discrete R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [12]. Note that this formula implies that all the ordinary Standard Model particles have even R-parity, whereas the corresponding supersymmetric partners have odd R-parity. The conservation of R-parity in scattering and decay

processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (R-even) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay quickly into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain of a heavy unstable supersymmetric particle. In order to be consistent with cosmological constraints, the LSP is almost certainly electrically and color neutral [13]. Consequently, the LSP is weakly-interacting in ordinary matter, *i.e.* it behaves like a neutrino and will escape detectors without being directly observed. Thus, the canonical signature for (R-parity conserving) supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Some model builders attempt to relax the assumption of R-parity conservation [14]. Models of this type must break B–L and are therefore strongly constrained. Nevertheless, because such models cannot be completely ruled out, it is important to allow for the possibility of R-parity violating processes in the search for supersymmetry. In particular, the LSP would be unstable, and this fact (among others) leads to a phenomenology of broken-R-parity models that is very different from that of the MSSM.

In the MSSM, supersymmetry breaking is induced by the soft-supersymmetry breaking terms mentioned above. These terms parametrize our ignorance of the fundamental mechanism of supersymmetry breaking. If this breaking occurs spontaneously, then (in the absence of supergravity) a massless Goldstone fermion called the *goldstino* ($\widetilde{G}$) must exist. The goldstino would then be the LSP and could play an important role in supersymmetric phenomenology [15]. In models that incorporate supergravity, this picture changes. If supergravity is spontaneously broken, the goldstino is absorbed ("eaten") by the *gravitino* ($g_{3/2}$), the spin-3/2 partner of the graviton [16]. By this super-Higgs mechanism, the gravitino acquires a mass ($m_{3/2}$). In models of this type; the gravitino mass is typically of order of the low-energy supersymmetry-breaking scale ($\mathcal{O}$(1 TeV)), while its couplings are gravitational in strength [1,17]. Such a gravitino would play no role in supersymmetric phenomenology at colliders.

The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the MSSM parameters can be found in Ref. 18. Among the parameters of the supersymmetry conserving sector are: (i) gauge couplings: g_s, g, and g', corresponding to the Standard Model gauge group SU(3)×SU(2)×U(1) respectively; (ii) Higgs Yukawa couplings: λ_e, λ_u, and λ_d (which are 3×3 matrices in flavor space); and (iii) a supersymmetry-conserving Higgs mass parameter μ. The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses M_3, M_2 and M_1 associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) scalar mass matrices for the squarks and sleptons; (iii) Higgs-squark-squark trilinear interaction terms (the so-called "A-parameters") and corresponding terms involving the sleptons; and (iv) three scalar Higgs mass parameters—two diagonal and one off-diagonal mass terms for the two Higgs doublets. These three mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_1 and v_2, and one physical Higgs mass. Here, v_1 (v_2) is the vacuum expectation value of the Higgs field which couples exclusively to down-type (up-type) quarks and leptons. Note that $v_1^2 + v_2^2 = (246\ \text{GeV})^2$ is fixed by the W mass (or equivalently by the Fermi constant G_F), while the ratio

$$\tan\beta = v_2/v_1 \qquad (1)$$

is a free parameter of the model. The supersymmetric constraints imply that the MSSM Higgs sector is automatically CP-conserving (at tree-level). Thus, $\tan\beta$ is a real parameter (conventionally chosen to be positive), and the physical neutral Higgs scalars are CP-eigenstates. Nevertheless, the MSSM does contain a number of possible new sources of CP violation. For example, gaugino mass parameters, the A-parameters, and μ may be complex. Some combination of these complex phases must be less than of order 10^{-2}–10^{-3} (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [19]. However, these complex phases have little impact on the direct searches for supersymmetric particles, and are usually ignored in experimental analyses.

Before describing the supersymmetric particle sector, let us consider the Higgs sector of the MSSM [20]. There are five physical Higgs particles in this model: a charged Higgs pair ($H^\pm$), two CP-even neutral Higgs bosons (denoted by H_1^0 and H_2^0 where $m_{H_1^0} \leq m_{H_2^0}$) and one CP-odd neutral Higgs boson (A^0). The properties of the Higgs sector are determined by the Higgs potential which is made up of quadratic terms [whose squared-mass coefficients were mentioned above Eq. (1)] and quartic interaction terms. The strengths of the interaction terms are directly related to the gauge couplings by supersymmetry (and are not affected at tree-level by supersymmetry-breaking). As a result, $\tan\beta$ [defined in Eq. (1)] and one Higgs mass determine: the Higgs spectrum, an angle α [which indicates the amount of mixing of the original $Y = \pm 1$ Higgs doublet states in the physical CP-even scalars], and the Higgs boson couplings. When one-loop radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [21,22]. For example, at tree-level, the MSSM predicts $m_{H_1^0} \leq m_Z$ [7,8]. If true, this would imply that experiments to be performed at LEP-II operating at its maximum energy and luminosity would rule out the MSSM if H_1^0 were not found. However, this Higgs mass bound need not be respected when radiative corrections are incorporated. For example, in Ref. 21, the following upper

bound was obtained for $m_{H_1^0}$ (assuming $m_{A^0} > m_Z$) in the limit of $m_Z \ll m_t \ll M_{\tilde{t}}$ [where top-squark ($\tilde{t}_L$-$\tilde{t}_R$) mixing is neglected]

$$m^2_{H_1^0} \lesssim m_Z^2 + \frac{3g^2 m_Z^4}{16\pi^2 m_W^2} \times \left\{ \ln\left(\frac{M_{\tilde{t}}^2}{m_t^2}\right)\left[\frac{2m_t^4 - m_t^2 m_Z^2}{m_Z^4}\right] + \frac{m_t^2}{3m_Z^2}\right\}. \quad (2)$$

For a top-squark mass of $M_{\tilde{t}} = 1$ TeV, Eq. (2) yields a positive mass shift for $m_{H_1^0}$ of about 20 GeV for $m_t = 150$ GeV, and 40 GeV for $m_t = 180$ GeV. Even if $\tan\beta = 1$ (so that $m_{H_1^0} = 0$ at tree-level), there is a large shift in $m^2_{H_1^0}$ due to radiative corrections of similar size. Clearly, the radiative corrections to the Higgs masses can have a significant impact on the search for the Higgs bosons of the MSSM at LEP and LEP-II [23].

Consider next the supersymmetric particle sector of the MSSM. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" at the end of the corresponding Standard Model particle name. The *gluino* is the color octet Majorana fermion partner of the gluon with mass $M_{\tilde{g}} = |M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the *gauginos* and *Higgsinos*) can mix. As a result, the physical mass eigenstates are model-dependent linear combinations of these states, called *charginos* and *neutralinos*, which are obtained by diagonalizing the corresponding mass matrices. The chargino mass matrix depends on M_2, μ, $\tan\beta$ and m_W [24]. The corresponding chargino mass eigenstates denoted by $\widetilde{\chi}_1^+$ and $\widetilde{\chi}_2^+$, with masses

$$M^2_{\widetilde{\chi}_1^+,\widetilde{\chi}_2^+} = \tfrac{1}{2}\left[|\mu|^2 + |M_2|^2 + 2m_W^2\right] \mp \left\{ \left(|\mu|^2 + |M_2|^2 + 2m_W^2\right)^2 - 4|\mu|^2|M_2|^2 - 4m_W^4 \sin^2 2\beta + 8m_W^2 \sin 2\beta\, \mathrm{Re}(\mu M_2)\right\}^{1/2}, \quad (3)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^+} \leq M_{\widetilde{\chi}_2^+}$. If CP-violating effects are ignored (in which case, M_2 and μ are real parameters), then one can choose a convention where $\tan\beta$ and M_2 are positive. (Note that the relative sign of M_2 and μ is meaningful. The sign of μ is convention-dependent; the reader is warned that both sign conventions appear in the literature.) The sign convention for μ implicit in Eq. (3) is used by the LEP collaborations [25] in their plots of exclusion contours in the M_2 *vs.* μ plane derived from the non-observation of $Z \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-$. The neutralino mass matrix depends on M_1, M_2, μ, $\tan\beta$, m_Z, and the weak mixing angle θ_W [24]. The corresponding neutralino eigenstates are usually denoted by $\widetilde{\chi}_i^0$ ($i = 1, \ldots 4$), according to the convention that $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$. If a chargino or neutralino eigenstate approximates a particular gaugino or Higgsino state, it may be convenient to use the corresponding nomenclature. For example, if M_1 and M_2 are small compared to m_Z (and μ), then the lightest neutralino $\widetilde{\chi}_1^0$ will be nearly a pure photino, $\widetilde{\gamma}$ (the supersymmetric partner of the photon). It is common practice in the literature to reduce the supersymmetric parameter freedom by requiring that all three gaugino mass parameters are equal at some grand unification scale. Then, at the electroweak scale, the gaugino mass parameters can be expressed in terms of one of them (say, M_2). The other two gaugino mass parameters are given by

$$M_3 = (g_s^2/g^2)M_2 \qquad M_1 = (5g'^2/3g^2)M_2\ . \quad (4)$$

Having made this assumption, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ, and $\tan\beta$.

The supersymmetric partners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*. For a given fermion f, there are two supersymmetric partners $\widetilde{f}_L$ and $\widetilde{f}_R$ which are scalar partners of the corresponding left and right-handed fermion. (There is no $\widetilde{\nu}_R$.) However, in general, $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass-eigenstates since there is $\widetilde{f}_L$-$\widetilde{f}_R$ mixing which is proportional in strength to the corresponding element of the scalar mass-squared-matrix [26]:

$$M^2_{LR} = \begin{cases} m_d(A_d - \mu\tan\beta), & \text{for "down"-type } f \\ m_u(A_u - \mu\cot\beta), & \text{for "up"-type } f, \end{cases} \quad (5)$$

where m_d (m_u) is the mass of the appropriate "down" ("up") type quark or lepton. Here, A_d and A_u are (unknown) soft-supersymmetry-breaking A-parameters and μ and $\tan\beta$ have been defined earlier. The signs of the A parameters are also convention-dependent; see Ref. 18. Due to the appearance of the *fermion* mass in Eq. (5), one expects M_{LR} to be small compared to the diagonal squark and slepton masses, with the possible exception of the top-squark, since m_t is large, and the bottom squark and τ slepton if $\tan\beta \gg 1$. The (diagonal) L and R-type squark and slepton masses are given by [2]

$$M^2_{\widetilde{u}_L} = M^2_{\widetilde{Q}} + m_u^2 + m_Z^2\cos 2\beta(\tfrac{1}{2} - \tfrac{2}{3}\sin^2\theta_W) \quad (6)$$

$$M^2_{\widetilde{u}_R} = M^2_{\widetilde{U}} + m_u^2 + \tfrac{2}{3}m_Z^2\cos 2\beta\sin^2\theta_W \quad (7)$$

$$M^2_{\widetilde{d}_L} = M^2_{\widetilde{Q}} + m_d^2 - m_Z^2\cos 2\beta(\tfrac{1}{2} - \tfrac{1}{3}\sin^2\theta_W) \quad (8)$$

$$M^2_{\widetilde{d}_R} = M^2_{\widetilde{D}} + m_d^2 - \tfrac{1}{3}m_Z^2\cos 2\beta\sin^2\theta_W \quad (9)$$

$$M^2_{\widetilde{\nu}} = M^2_{\widetilde{L}} + \tfrac{1}{2}m_Z^2\cos 2\beta \quad (10)$$

$$M^2_{\widetilde{e}_L} = M^2_{\widetilde{L}} + m_e^2 - m_Z^2\cos 2\beta(\tfrac{1}{2} - \sin^2\theta_W) \quad (11)$$

$$M^2_{\widetilde{e}_R} = M^2_{\widetilde{E}} + m_e^2 - m_Z^2\cos 2\beta\sin^2\theta_W\,. \quad (12)$$

The soft-supersymmetry-breaking parameters: $M_{\widetilde{Q}}$, $M_{\widetilde{U}}$, $M_{\widetilde{D}}$, $M_{\widetilde{L}}$, and $M_{\widetilde{E}}$ are unknown parameters. In the equations above, the notation of first generation fermions has been used and generational indices have been suppressed. Further complications such as intergenerational mixing are possible, although there are some constraints from the nonobservation of flavor-changing neutral currents (FCNC) [27].

One way to guarantee the absence of significant FCNC's mediated by virtual supersymmetric particle exchange is to posit that the diagonal soft-supersymmetry-breaking scalar mass matrices are proportional to the unit matrix (in flavor space) at some energy scale (normally taken to be the Planck scale) [28]. Renormalization group evolution is used to determine the low-energy values for the scalar mass parameters listed above. This assumption substantially reduces the MSSM parameter freedom. For example, supersymmetric grand unified models with universal scalar masses at the Planck scale typically give [29] $M_{\widetilde{L}} \approx M_{\widetilde{E}} < M_{\widetilde{Q}} \approx M_{\widetilde{U}} \approx M_{\widetilde{D}}$ with the squark masses somewhere between a factor of 1–3 larger than the slepton masses (neglecting generational distinctions). More specifically, the first two generations are thought to be nearly degenerate in mass, while $M_{\widetilde{Q}_3}$ and $M_{\widetilde{U}_3}$ are typically reduced by a factor of 1–3 from the other soft-supersymmetry-breaking masses because of renormalization effects due to the heavy top quark mass. As a result, four flavors of squarks (with two squark eigenstates per flavor) and $\widetilde{b}_R$ will be nearly mass-degenerate and somewhat heavier than six flavors of nearly mass-degenerate sleptons (with two per flavor for the charged sleptons and one per flavor for the sneutrinos). On the other hand, the $\widetilde{b}_L$ mass and the diagonal $\widetilde{t}_L$ and $\widetilde{t}_R$ masses are reduced compared to the common squark mass of the first two generations. In addition, third generation squark masses and τ slepton masses are sensitive to the strength of the respective $\widetilde{f}_L$-$\widetilde{f}_R$ mixing as discussed below Eq. (5).

Two additional theoretical frameworks are often introduced to reduce further the MSSM parameter freedom [1,2,30]. The first is that of grand unified theories (GUTs) and the desert hypothesis (*i.e* no new physics between the TeV-scale and the GUT-scale). In the absence of low-energy supersymmetry, the simplest models of this type fail because the three SU(3)×SU(2)×U(1) gauge couplings fail to unify at a common scale [31,32]. Remarkably, in the case of the MSSM (with a supersymmetry-breaking scale of order 1 TeV or below), the three gauge couplings do unify at a common energy scale of order 10^{16} GeV (with only very mild assumptions about the GUT-scale theory) [31,33]. Unification constraints on the Higgs-fermion Yukawa couplings may also exist but are more GUT-model dependent [34]. The second theoretical framework is that of minimal supergravity theory, which can impose nontrivial constraints on the soft-supersymmetry breaking parameters. Referring to the parameter list given above Eq. (1), the Planck-scale values of the soft-supersymmetry-breaking parameters in the simplest supergravity models take the following form: (i) a universal gaugino mass $m_{1/2}$ [assuming grand unification; Eq. (4) is a consequence of this assumption]; (ii) a universal diagonal scalar mass parameter m_0 [whose consequences were described in the preceding paragraph]; (iii) a universal A-parameter, A_0; and (iv) three scalar Higgs mass parameters—two common diagonal squared-masses given by $|\mu_0|^2 + m_0^2$ and an off-diagonal squared-mass given by $B_0\mu_0$ (which defines the Planck-scale supersymmetry-breaking parameter B_0), where μ_0 is the Planck-scale value of the μ-parameter. As before, renormalization group evolution is used to compute the low-energy values of the supersymmetry-breaking parameters and determines the supersymmetric particle spectrum. Moreover, in this approach, electroweak symmetry breaking is induced radiatively if one of the Higgs diagonal squared-masses is forced negative by the evolution. This occurs in models with a large Higgs-top quark Yukawa coupling (*i.e.* large m_t). As a result, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure [29] is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ (the sign of μ_0 is not fixed in this process). In this case, the MSSM spectrum and its interactions are determined by m_0, A_0, $m_{1/2}$, $\tan\beta$, and the sign of μ_0 (in addition to the parameters of the Standard Model). Combining both grand unification and the minimal supergravity approach yield the most constrained version of the MSSM.

Nonminimal versions of low-energy supersymmetry can also be constructed. These models add additional matter and/or gauge super-multiplets to the MSSM (at the TeV scale or below). Experimental and theoretical constraints place some restrictions on these approaches, although no comprehensive treatment has yet appeared in the literature.

MINIMAL SUPERSYMMETRIC STANDARD MODEL ASSUMPTIONS

All results shown below (except where stated otherwise) are based on the Minimal Supersymmetric Standard Model (MSSM) as described in the Note on Supersymmetry. This includes the assumption that R-parity is conserved. In addition the following assumptions are made in most cases:

1) The $\tilde{\chi}_1^0$ (or $\tilde{\gamma}$) is the lightest supersymmetric particle (LSP).

2) $m_{\tilde{f}_L} = m_{\tilde{f}_R}$ where $\tilde{f}_L$ and $\tilde{f}_R$ refer to the scalar partners of left-and right-handed fermions.

Limits involving different assumptions either are identified with comments or are in the miscellaneous section.

When needed, specific assumptions of the eigenstate content of neutralinos and charginos are indicated (use of the notation $\tilde{\gamma}$ (photino), $\tilde{H}$ (Higgsino), $\tilde{W}$ (w-ino), and $\tilde{Z}$ (z-ino) indicates the approximation of a pure state was made).

$\tilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

$\tilde{\chi}_1^0$ is likely to be the lightest supersymmetric particle (LSP). See also the $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ section below.

We have divided the $\tilde{\chi}_1^0$ listings below into three sections: 1) Accelerator limits for $\tilde{\chi}_1^0$, 2) Bounds on $\tilde{\chi}_1^0$ from dark matter searches, and 3) Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology.

Accelerator limits for $\tilde{\chi}_1^0$

These papers generally exclude regions in the $M_2 - \mu$ parameter plane based on accelerator experiments. Unless otherwise stated, these papers assume minimal supersymmetry and GUT relations (gaugino-mass unification condition).

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>20	95	[1] DECAMP	92	ALEP	$\tilde{\chi}_1^0$, $\tan\beta > 3$
>18.4	90	[2] HIDAKA	91	RVUE	$\tilde{\chi}_1^0$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>18.8		[3] BAER	91	RVUE	$\tilde{\chi}_1^0$; $\tan\beta > 1.6$
> (10–13)	90	[4] ROSZKOWSKI	90	RVUE	$\tilde{\chi}_1^0$; $\tan\beta \geq 1$
>5 GeV	90	[5] HEARTY	89	ASP	$\tilde{\gamma}$; for $m_{\tilde{e}} < 55$ GeV

[1] DECAMP 92 limit for $\tan\beta > 2$ is $m > 13$ GeV.
[2] HIDAKA 91 limit obtained from LEP and preliminary CDF results (as analyzed in BAER 91).
[3] BAER 91 limit obtained from LEP and preliminary CDF results assuming $\tan\beta > 1.6$.
[4] ROSZKOWSKI 90 limit obtained from ALEPH and CDF/UA2 results assuming $\tan\beta \geq 1$.
[5] HEARTY 89 assumed pure $\tilde{\gamma}$ eigenstate and $m_{\tilde{e}_L} = m_{\tilde{e}_R}$. There is no limit for $m_{\tilde{e}} > 58$ GeV. Uses $e^+e^- \to \gamma\tilde{\gamma}\tilde{\gamma}$. No GUT relation assumptions are made.

Bounds on $\tilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2 - \mu$ parameter plane assuming that $\tilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments or by the absence of a signal in underground neturino detectors. The latter signal is expected if $\tilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν's.

VALUE	DOCUMENT ID		TECN
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	[6] MORI	93	KAMI
	[7] BOTTINO	92	COSM
	[8] BOTTINO	91	RVUE
	[9] GELMINI	91	COSM
	[10] KAMIONKOW.	91	RVUE
	[11] MORI	91B	KAMI
none 4–15 GeV	[12] OLIVE	88	COSM

[6] MORI 93 excludes some region in M_2–μ parameter space depending on tanβ and lightest scalar Higgs mass for neutralino dark matter $m_{\tilde{\chi}^0} > m_W$, using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

[7] BOTTINO 92 excludes some region M_2-μ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.

[8] BOTTINO 91 excluded a region in $M_2 - \mu$ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson.

[9] GELMINI 91 exclude a region in $M_2 - \mu$ plane using dark matter searches.

[10] KAMIONKOWSKI 91 excludes a region in the M_2–μ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim 50$ GeV. See Fig. 8 in the paper.

[11] MORI 91B exclude a part of the region in the M_2–μ plane with $m_{\tilde{\chi}_1^0} \lesssim 80$ GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim 80$ GeV.

[12] OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

[13] Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde{H}} \lesssim 1$ TeV.

[14] Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 550$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde{H}} \lesssim 3.2$ TeV.

[15] GRIFOLS 90 argues that SN1987A data exclude a light photino ($\lesssim 1$ MeV) if $m_{\tilde{q}} < 1.1$ TeV, $m_{\tilde{e}} < 0.83$ TeV.

[16] ELLIS 88B argues that the observed neutrino flux from SN 1987A is inconsistent with a light photino if 60 GeV $\lesssim m_{\tilde{q}} \lesssim 2.5$ TeV. If m(higgsino) is O(100 eV) the same argument leads to limits on the ratio of the two Higgs v.e.v.'s. LAU 93 discusses possible relations of ELLIS 88B bounds.

[17] KRAUSS 83 finds $m_{\tilde{\gamma}}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\tilde{\gamma}}$ = 4–20 MeV exists if $m_{\text{gravitino}}$ <40 TeV. See figure 2.

$\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, and $\tilde{\chi}_4^0$. $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{e}$, $\tilde{\gamma}$, $\tilde{q}$, $\tilde{g}$), and on the $\tilde{e}$ mass exchanged in $e^+e^- \to \tilde{\chi}_i^0\tilde{\chi}_j^0$. Often limits are given as contour plots in the $m_{\tilde{\chi}^0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g. the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino ($\tilde{Z}$), or pure neutral higgsino ($\tilde{H}^0$), the neutralinos will be labelled as such.

[18] DECAMP 92 result is within minimal supersymmetry with gaugino-mass unification condition. For tanβ >2 the limit is >40 GeV; and it disappears for tanβ < 1.6.

[19] HIDAKA 91 limit obtained from LEP and preliminary CDF results (as analyzed in BAER 91) within minimal supersymmetry with gaugino-mass unification condition.

[20] ABREU 90G exclude $B(Z \to \tilde{\chi}_1^0\tilde{\chi}_2^0) \geq 10^{-3}$ and $B(Z \to \tilde{\chi}_2^0\tilde{\chi}_2^0) \geq 2 \times 10^{-3}$ assuming $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 f\bar{f}$ via virtual Z. These exclude certain regions in model parameter space, see their Fig. 5.

[21] AKRAWY 90N exclude $B(Z \to \tilde{\chi}_1^0\tilde{\chi}_2^0) \gtrsim 3\text{–}5 \times 10^{-4}$ assuming $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 f\bar{f}$ or $\tilde{\chi}_1^0\gamma$ for most accessible masses. These exclude certain regions in model parameter space, see their Fig. 7.

[22] BAER 90 is independent of decay modes. Limit from analysis of supersymmetric parameter space restrictions implied by $\Delta\Gamma(Z) < 120$ MeV. These result from decays of Z to all combinations of $\tilde{\chi}_i^\pm$ and $\tilde{\chi}_j^0$. Minimal supersymmetry with tanβ > 1 is assumed.

[23] See Figs. 4, 5 in BARKLOW 90 for the excluded regions.

[24] DECAMP 90K exclude certain regions in model parameter space, see their figures.

[25] SAKAI 90 assume $m_{\tilde{H}_1^0} = 0$. The limit is for $m_{\tilde{H}_2^0}$.

[26] Pure $\tilde{\gamma}$ and pure $\tilde{Z}$ eigenstates. $B(\tilde{Z} \to q\bar{q}\tilde{\gamma}) = 0.60$ and $B(\tilde{Z} \to e^+e^-\tilde{\gamma}) = 0.13$. $m_{\tilde{e}_L} = m_{\tilde{e}_R} < 70$ GeV. $m_{\tilde{\gamma}} < 10$ GeV.

[27] Pure $\tilde{\gamma}$ and pure $\tilde{Z}$ eigenstates. $B(\tilde{Z} \to q\bar{q}\tilde{g}) = 1$. $m_{\tilde{e}_L} = m_{\tilde{e}_R} < 70$ GeV. $m_{\tilde{\gamma}} = 0$.

[28] Pure higgsino. The LSP is the other higgsino and is taken massless. Limit degraded if $\tilde{\chi}^0$ not pure higgsino or if LSP not massless.

[29] Pure $\tilde{\gamma}$ and pure $\tilde{Z}$ eigenstates. $B(\tilde{Z} \to \bar{\nu}\nu) = 1$. $m_{\tilde{e}_L} = m_{\tilde{e}_R} = 26$ GeV. $m_{\tilde{\gamma}} = 10$ GeV. No excluded region remains for $m_{\tilde{e}}$ >30 GeV.

[30] AKERLOF 85 is e^+e^- monojet search motivated by UA1 monojet events. Observed only one event consistent with $e^+e^- \to \tilde{\gamma}+\tilde{\chi}^0$ where $\tilde{\chi}^0 \to$ monojet. Assuming that missing-p_T is due to $\tilde{\gamma}$, and monojet due to $\tilde{\chi}^0$, limits dependent on the mixing and $m_{\tilde{e}}$ are given, see their figure 4.

[31] BARTEL 85L assume $m_{\tilde{H}_1^0} = 0$, $\Gamma(Z \to \tilde{H}_1^0\tilde{H}_2^0) \gtrsim \frac{1}{2}\Gamma(Z \to \nu_e\bar{\nu}_e)$. The limit is for $m_{\tilde{H}_2^0}$.

[32] BEHREND 85 find no monojet at E_{cm} = 40–46 GeV. Consider $\tilde{\chi}^0$ pair production via Z^0. One is assumed as massless and escapes detector. Limit is for the heavier one, decaying into a jet and massless $\tilde{\chi}^0$. Both $\tilde{\chi}^0$'s are assumed to be pure higgsino. For these very model-dependent results, BEHREND 85 excludes m = 1.5–19.5 GeV.

[33] ADEVA 84B observed no events with signature of acoplanar lepton pair with missing energy. Above example limit is for $m_{\tilde{\gamma}}$ <2 GeV and $m_{\tilde{e}}$ <40 GeV, and assumes $B(\tilde{Z} \to \mu^+\mu^-\tilde{\gamma}) = B(\tilde{Z} \to e^+e^-\tilde{\gamma}) = 0.10$. BR = 0.05 gives 33.5 GeV limit.

[34] BARTEL 84C search for $e^+e^- \to \tilde{Z}+\tilde{\gamma}$ with $\tilde{Z} \to \tilde{\gamma}+e^+e^-$, $\mu^+\mu^-$, $q\bar{q}$, etc. They see no acoplanar events with missing-p_T due to two $\tilde{\gamma}$'s. Above example limit is for $m_{\tilde{e}}$ = 40 GeV and for light stable $\tilde{\gamma}$ with $B(\tilde{Z} \to e^+e^-\tilde{\gamma}) = 0.1$.

[35] ELLIS 84 find if lightest neutralino is stable, then $m_{\tilde{\chi}^0}$ not 100 eV – 2 GeV (for $m_{\tilde{q}}$ = 40 GeV). The upper limit depends on $m_{\tilde{q}}$ (similar to the $\tilde{\gamma}$ limit) and on nature of $\tilde{\chi}^0$. For pure higgsino the higher limit is 5 GeV.

$\tilde{\chi}_1^\pm$, $\tilde{\chi}_2^\pm$ (Charginos) MASS LIMITS

Charginos ($\tilde{\chi}^\pm$'s) are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). Mass limits are relatively model dependent, so assumptions concerning branching ratios need to be specified. When specific assumptions are made, e.g. the chargino is a pure w-ino ($\widetilde{W}$) or pure charged higgsino ($\tilde{H}^\pm$), the charginos will be labelled as such.

[36] ADRIANI 93M limit from $\Delta\Gamma(Z)$< 35.1 MeV. For pure wino, the limit is 45.5 GeV.

[37] DECAMP 92 limit is for a general $\tilde{\chi}^\pm$ (all contents).

[38] HIDAKA 91 limit obtained from LEP and preliminary CDF results (as analyzed in BAER 91) within minimal supersymmetry with gaugino-mass unification condition.

[39] ABREU 90G limit is for a general $\tilde{\chi}^\pm$. They assume charginos have a three-body decay such as $\ell^\pm\nu\tilde{\gamma}$.

[40] AKRAWY 90D assume charginos have three-body decay such as $\ell^\pm\nu\tilde{\gamma}$ (i.e. $m_{\tilde{\nu}} > m_{\tilde{\chi}^+}$). A two-body decay, $\tilde{\chi}^+ \to \ell\tilde{\nu}$ would have been seen by their search for acoplanar leptons. The result is independent of the hadronic branching ratio. They search for acoplanar electromagnetic clusters and quark jets.

[41] DATTA 92 exclude some regions in chargino-gluino mass plane from LEP experiments.

[42] DREES 91 limit obtained from LEP results within minimal supersymmetry with gaugino-mass unification condition. They make use of DECAMP 90C analysis plus additional constraint from total Z width. The bound can only be evaded if the chargino mixes with other charged singlets or with gauginos of a right-handed gauge group.

[43] AKESSON 90B assume $\widetilde{W} \to e\tilde{\nu}$ with B > 20% and $m_{\tilde{\nu}} = 0$. The limit disappears if $m_{\tilde{\nu}} > 30$ GeV.

[44] BAER 90 is independent of decay modes. Limit from analysis of supersymmetric parameter space restrictions implied by $\Delta\Gamma(Z) < 120$ MeV. These result from decays of Z to all combinations of $\tilde{\chi}_I^\pm$ and $\tilde{\chi}_J^0$. Minimal supersymmetry with $\tan\beta > 1$ is assumed.

[45] BARKLOW 90 assume 100% $\widetilde{W} \to W^*\tilde{\chi}_1^0$. Valid up to $m_{\tilde{\chi}_1^0} \lesssim [m_{\widetilde{W}} - 5$ GeV].

[46] BARKLOW 90 assume 100% $\tilde{H} \to H^*\tilde{\chi}_1^0$. Valid up to $m_{\tilde{\chi}_1^0} \lesssim [m_{\tilde{H}} - 8$ GeV].

[47] DECAMP 90C assume charginos have three-body decay such as $\ell^+\nu\tilde{\gamma}$ (i.e. $m_{\tilde{\nu}} > m_{\tilde{\chi}^+}$), and branching ratio to each lepton is 11%. They search for acoplanar dimuons, dielectrons, and μe events. Limit valid for $m_{\tilde{\gamma}} < 28$ GeV.

[48] ADACHI 89 assume only single photon annihilation in the production. The limit applies for arbitrary decay branching ratios with $B(\tilde{\chi} \to e\nu\tilde{\gamma}) + B(\tilde{\chi} \to \mu\nu\tilde{\gamma}) + B(\tilde{\chi} \to \tau\nu\tilde{\gamma}) + B(\tilde{\chi} \to q\bar{q}\tilde{\gamma}) = 1$ (lepton universality is *not* assumed). The limit is for $m_{\tilde{\gamma}} = 0$ but a very similar limit is obtained for $m_{\tilde{\gamma}} = 10$ GeV. For $B(\tilde{\chi} \to q\bar{q}\tilde{\gamma}) = 1$, the limit increases to 27.8 GeV.

[49] ADEVA 89B assume for $\ell\nu\tilde{\gamma}$ ($\ell\tilde{\nu}$) mode that $B(e) = B(\mu) = B(\tau) = 11\%$ (33%) and search for acoplanar dimuons, dielectrons, and μe events. Also assume $m_{\tilde{\gamma}} < 20$ GeV and for $\ell\tilde{\nu}$ mode that $m_{\tilde{\nu}} = 10$ GeV.

[50] ANSARI 87D looks for high p_T e^+e^- pair with large missing p_T at the CERN $p\bar{p}$ collider at $E_{cm} = 546$–630 GeV. The limit is valid when $m_{\tilde{\nu}} \lesssim 20$ GeV, $B(\widetilde{W} \to e\tilde{\nu}_e) = 1/3$, and $B(Z \to \widetilde{W}^+\widetilde{W}^-)$ is calculated by assuming pure gaugino eigenstate. See their Fig. 3(b) for excluded region in the $m_{\widetilde{W}} - m_{\tilde{\nu}}$ plane.

[51] BAER 87B argue that the charged heavy lepton mass limit of 41 GeV obtained by UA1 collaboration (ALBAJAR 87B) corresponds to the mass limit of 40 GeV under the assumptions that the LSP (photino) has a mass smaller than 8 GeV and that the gaugino-higgsino mixing is parametrized by the three minimal supergravity model parameters. In grand unified theories $m_{\tilde{\gamma}} < 8$ implies $m_{\tilde{g}} < 50$ GeV. For larger gluino masses, this limit can be evaded as discussed in BAER 88.

$\tilde{\nu}$ (Sneutrino) MASS LIMIT

The limit depends on the number, $N(\tilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\tilde{\nu}_L$ (not $\tilde{\nu}_R$) exist. It is possible that $\tilde{\nu}$ could be the lightest supersymmetric particle (LSP).

[60] ADRIANI 93M limit is for $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$ using acolinear di-lepton events.

[61] DECAMP 92 limit is for $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$; for equal masses the limit would improve. They looked for acoplanar electrons.

[62] HEARTY 89 assume $m_{\tilde{\gamma}} = 0$. The limit is very sensitive to $m_{\tilde{\gamma}}$; no limit can be placed for $m_{\tilde{\gamma}} \gtrsim 13$ GeV.

[63] Results of HEARTY 89, BEHREND 88B, ADEVA 87, and FORD 86 are combined. The limit is reduced to 53 GeV if only one $\tilde{e}$ state is produced ($\tilde{e}_L$ or $\tilde{e}_R$ very heavy).

[64] AKESSON 90B assume $m_{\tilde{\gamma}} = 0$. Very similar limits hold for $m_{\tilde{\gamma}} \lesssim 20$ GeV.

[65] AKRAWY 90D look for acoplanar electrons. For $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$, limit is 41.5 GeV, for $m_{\tilde{\gamma}} < 30$ GeV.

[66] BAER 90 limit from $\Delta\Gamma(Z)$ (nonhadronic) < 53 MeV. Independent of decay modes. Minimal supersymmetry and $\tan\beta > 1$ assumed.

[67] DECAMP 90C look for acoplanar electrons. For $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$ limit is 42 GeV, for $m_{\tilde{\gamma}} < 33$ GeV.

[68] ZHUKOVSKII 90 set limit by saying the luminosity of a magnetized neutron star due to massless photino emission by electrons be small compared with its neutrino luminosity.
[69] ABE 89K assumed $m_{\tilde{\gamma}} = 0$.
[70] ADACHI 89 assume only photon and photino exchange and $m_{\tilde{e}_L} = m_{\tilde{e}_R}$. The limit for the nondegenerate case is 26 GeV.
[71] ADEVA 89B look for acoplanar electrons.
[72] ALBAJAR 89 limit applies for $\tilde{e}_L$ when $m_{\tilde{e}_L} = m_{\tilde{\nu}_L}$ and $m_{\tilde{\gamma}} = 0$. See their Fig. 55 for the 90% CL excluded region in the $m_{\tilde{e}_L} - m_{\tilde{\nu}_L}$ plane. For $m_{\tilde{\nu}} = m_{\tilde{\gamma}} = 0$, limit is 50 GeV.
[73] ALBAJAR 89 assume $m_{\tilde{\gamma}} = 0$.
[74] The limit is reduced to 43 GeV if only one $\tilde{e}$ state is produced ($\tilde{e}_L$ or $\tilde{e}_R$ very heavy).
[75] BEHREND 88B limits assume pure photino eigenstate and $m_{\tilde{e}_L} = m_{\tilde{e}_R}$.
[76] The 95% CL limit for BEHREND 88B is 47.5 GeV for $m_{\tilde{\gamma}} = 0$. The limit for $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$ is 40 GeV at 90% CL.
[77] BEHREND 88B combined their data with those from ASP (HEARTY 87), MAC (FORD 86), and MARK-J (H. Wu, Ph. D. Thesis, University of Hamburg, 1986).

$\tilde{\mu}$ (Smuon) MASS LIMIT

[86] DECAMP 92 limit is for $m_{\tilde{\tau}_L} \gg m_{\tilde{\tau}_R}$; for equal masses the limit would improve. They looked for acoplanar particles.
[87] AKRAWY 90D look for acoplanar particles. For $m_{\tilde{\tau}_L} \gg m_{\tilde{\tau}_R}$, limit is 41.0 GeV, for $m_{\tilde{\gamma}} < 23$ GeV.
[88] BAER 90 limit from $\Delta\Gamma(Z)$ (nonhadronic) < 53 MeV. Independent of decay modes. Mininal supersymmetry and tan$\beta > 1$ assumed.
[89] DECAMP 90C look for acoplanar charged particle pairs. Limit is for $m_{\tilde{\tau}_L} = m_{\tilde{\tau}_R}$. For $m_{\tilde{\gamma}} \leq 24$ GeV, the limit is 37 GeV. For $m_{\tilde{\tau}_L} \gg m_{\tilde{\tau}_R}$ and $m_{\tilde{\gamma}} < 15$ GeV, the limit is 33 GeV.
[90] ADACHI 89 assume only photon exchange, which gives a conservative limit. $m_{\tilde{\tau}_L} = m_{\tilde{\tau}_R}$ assumed.

Stable $\tilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. However, selectron limits from continuum e^+e^- annihilation depend on flavor because there is an additional contribution from neutralino exchange that in general yields stronger limits. All limits assume $m_{\tilde{\ell}_L} = m_{\tilde{\ell}_R}$ unless otherwise stated.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>40	95	ABREU	90G	DLPH	
• • • We do not use the following data for averages, fits, limits, etc. • • •

[91] SAKAI 90 limit improves to 30.1 GeV for $\tilde{e}$ if $m_{\tilde{\gamma}} \approx m_{\tilde{e}}$.
[92] ADACHI 89 assume only photon (and photino for $\tilde{e}$) exchange. The limit for $\tilde{e}$ improves to 26 GeV for $m_{\tilde{\gamma}} \approx m_{\tilde{e}}$.

$\tilde{q}$ (Squark) MASS LIMIT

For $m_{\tilde{q}} > 60$–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. When direct decay is assumed, realistic limits would be somewhat lower. The limits from Z decay do not assume GUT relations and are more model independent.

> 45	90	[110] ALBAJAR	87D	UA1	Any $m_{\tilde{g}} > m_{\tilde{q}}$
> 75	90	[110] ALBAJAR	87D	UA1	$m_{\tilde{g}} = m_{\tilde{q}}$

[93] ABE 92L assume five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. ABE 92L includes the effect of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, tan$\beta =$ 2. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\tilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if B($\tilde{q} \to q\tilde{\gamma}$) = 1. Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}^0_1} \approx m_{\tilde{g}}/6$. This last relation implies that as $m_{\tilde{g}}$ increases, the mass of $\tilde{\chi}^0_1$ will eventually exceed $m_{\tilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\tilde{g}}$ >410 GeV.
[94] ADRIANI 93M limit from $\Delta\Gamma(Z)$< 35.1 MeV and assumes $m_{\tilde{q}_L} \gg m_{\tilde{q}_R}$.
[95] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay $\tilde{q} \to q\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\bar{d}$ or $\ell\ell\bar{e}$ is assumed.
[96] BAER 91B argue that a top squark as light as 45 GeV may have escaped detection at the CDF detector at the Tevatron Collider (45 GeV is the limit from LEP experiments).

[97] NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

[98] ABREU 90F assume six degenerate squarks and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. $m_{\tilde{q}} < 41$ GeV is excluded at 95% CL for $m_{LSP} < m_{\tilde{q}} - 2$ GeV.

[99] ABREU 90F exclude $m_{\tilde{d}} < 38$ GeV at 95% for $m_{LSP} < m_{\tilde{d}} - 2$ GeV.

[100] ABREU 90F exclude $m_{\tilde{u}} < 36$ GeV at 95% for $m_{LSP} < m_{\tilde{u}} - 2$ GeV.

[101] ALITTI 90 searched for events having $\geq$ 2 jets with $E_T^1 > 25$ GeV, $E_T^2 > 15$ GeV, $|\eta| < 0.85$, and $\Delta\phi < 160°$, with a missing momentum > 40 GeV and no electrons. They assume $\tilde{q} \to q\tilde{\gamma}$ (if $m_{\tilde{q}} < m_{\tilde{g}}$) or $\tilde{q} \to q\tilde{g}$ (if $m_{\tilde{q}} > m_{\tilde{g}}$) decay and $m_{\tilde{\gamma}} \lesssim$ 20 GeV. Five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$ are assumed. Masses below 50 GeV are not excluded by the analysis.

[102] BAER 90 limit from $\Delta\Gamma(Z) < 120$ MeV, assuming $m_{\tilde{d}_L} = m_{\tilde{u}_L} = m_{\tilde{e}_L} = m_{\tilde{\nu}}$. Independent of decay modes. Minimal supergravity assumed.

[103] BARKLOW 90 assume 100% $\tilde{q} \to q\tilde{\gamma}$.

[104] BARKLOW 90 assume five degenerate squarks (left- and right-handed). Valid up to $m_{\tilde{\chi}_1^0} \lesssim [m_{\tilde{q}} - 4$ GeV].

[105] BARKLOW 90 result valid up to $m_{\tilde{\chi}_1^0} \lesssim [m_{\tilde{d}} - 5$ GeV].

[106] BARKLOW 90 result valid up to $m_{\tilde{\chi}_1^0} \lesssim [m_{\tilde{u}} - 6$ GeV].

[107] DREES 90 argue that bounds from Z decay are not valid for $\tilde{t}$ for a certain range of $\tilde{t}_L$-$\tilde{t}_R$ mixing angle.

[108] ADACHI 89 assume only photon exchange, which gives a a conservative limit. The limit is only for one flavor of charge 2/3 $\tilde{q}$. $m_{\tilde{q}_L} = m_{\tilde{q}_R}$ and $m_{\tilde{\gamma}} = 0$ assumed. The limit decreases to 26.1 GeV for $m_{\tilde{\gamma}} = 15$ GeV. The limit for nondegenerate case is 24.4 GeV.

[109] NATH 88 uses Kamioka limit of $\tau(p \to \bar{\nu}K^+) > 7 \times 10^{31}$ yrs to constrain squark mass $m_{\tilde{q}} > 1000$ GeV by assuming that the proton decay proceeds via an exchange of a color-triplet Higgsino of mass $< 10^{16}$ GeV in the supersymmetric SU(5) GUT. The limit applies for $m_{\tilde{\gamma}} \equiv (8/3)\sin^2\theta_W \tilde{m}_2 > 10$ GeV ($\tilde{m}_2$ is the SU(2) gaugino mass) and for a very conservative value of the three-quark proton wave function, barring cancellation between second and third generations. Lower squark mass is allowed if $m_{\tilde{\gamma}}$ as defined above is smaller.

[110] The limits of ALBAJAR 87D are from $p\bar{p} \to \tilde{q}\bar{\tilde{q}}X$ ($\tilde{q} \to q\tilde{\gamma}$) and assume 5 flavors of degenerate mass squarks each with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. They also assume $m_{\tilde{g}} > m_{\tilde{q}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20$ GeV.

$\tilde{g}$ (Gluino) MASS LIMIT

For $m_{\tilde{g}} > 60$–70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. When direct decay is assumed, realistic limits would be somewhat lower.

There is an ongoing controversy (reflected in these Listings) about whether very light $\tilde{g}$'s ($1 \lesssim m_{\tilde{g}} \lesssim 4$ GeV) are ruled out. These papers sometimes make different assumptions and use different calculational techniques.

[111] ABE 92L includes the effect of cascade decay, for a particular choice of paramters, $\mu = -250$ GeV, tan$\beta = 2$. Results are mildly sensitive to these parameters over much of parameter space. ABE 92L limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}_1^0} \approx m_{\tilde{g}}/6$. Not sensitive to $m_{\tilde{g}} \leq 40$ GeV (but other experiments rule out that region). Limits are more substanial if B($\tilde{g} \to q\bar{q}\tilde{\gamma}$) = 1; for $m_{\tilde{q}} > m_{\tilde{g}}$ the limits are about 50 GeV greater.

[112] CLAVELLI 93 makes a two-dimensional fit to the quarkonia decay widths for $\phi(1020)$, $J/\psi(1S)$, $\psi(2S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ taking $\alpha_s(m_Z)$ and $m_{\tilde{g}}$ as variables. Claims that the fit favors $m_{\tilde{g}} < 1$ GeV, and that the fitted $\alpha_s(m_Z)$ is consistent with LEP data.

[113] HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks N=6.3 ± 1.1 is obtained, which is compared to that with a light gluino, N=8.

[114] LOPEZ 93C uses combined restraint from the radiative symmetry breaking scenario within the minimal supergravity model, and the LEP bounds on the (M_2,μ) plane. Claims that the light gluino window is strongly disfavored.

[115] CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between α_s at LEP and at quarkonia (Υ), since a light gluino slows the running of the QCD coupling.

[116] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g} \to q\bar{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\bar{q}$ or $\ell\ell\bar{e}$ is assumed.

[117] ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of α_s between 5 GeV and m_Z. The significance is less than 2 s.d.

[118] ANTONIADIS 91 intrepret the search for missing energy events in 450 GeV/c pN collisions, AKESSON 91, in terms of light gluinos.

[119] HIDAKA 91 limit obtained from LEP and preliminary CDF results within minimal supersymmetry with gaugino-mass unification condition. HIDAKA 91 limit extracted from BAER 91 analysis.

[120] NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

[121] ALITTI 90 searched for events having $\geq$ 2 jets with $E_T^1 > 25$ GeV, $E_T^2 > 15$ GeV, $|\eta| < 0.85$, and $\Delta\phi < 160°$, with a missing momentum > 40 GeV and no electrons. They assume $\tilde{g} \to q\bar{q}\tilde{\gamma}$ decay and $m_{\tilde{\gamma}} \lesssim 20$ GeV. Masses below 50 GeV are not excluded by the analysis.

[122] NAKAMURA 89 searched for a long-lived ($\tau \gtrsim 10^{-7}$ s) charge-(±2) particle with mass $\lesssim$ 1.6 GeV in proton-Pt interactions at 12 GeV and found that the yield is less than 10^{-8} times that of the pion. This excludes R-Δ^{++} (a $\tilde{g}uuu$ state) lighter than 1.6 GeV.

[123] The limits of ALBAJAR 87D are from $p\bar{p} \to \tilde{g}\tilde{g}X$ ($\tilde{g} \to q\bar{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20$ GeV and $\tau(\tilde{g}) < 10^{-10}$ s.

[124] The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.

[125] The limits assume $m_{\tilde{q}} = 100$ GeV. See their figure 3 for limits vs. $m_{\tilde{q}}$.

[126] The gluino mass is defined by half the bound $\tilde{g}\tilde{g}$ mass. If zero gluino mass gives a $\tilde{g}\tilde{g}$ of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.

[127] ALBRECHT 86C search for secondary decay vertices from $\chi_{b1}(1P) \to \tilde{g}\tilde{g}g$ where $\tilde{g}$'s make long-lived hadrons. See their figure 4 for excluded region in the $m_{\tilde{g}} - m_{\tilde{\gamma}}$ and $m_{\tilde{g}} - m_{\tilde{q}}$ plane. The lower $m_{\tilde{g}}$ region below ~ 2 GeV may be sensitive to fragmentation effects. Remark that the $\tilde{g}$-hadron mass is expected to be ~ 1 GeV (glueball mass) in the zero $\tilde{g}$ mass limit.

[128] BADIER 86 looked for secondary decay vertices from long-lived $\tilde{g}$-hadrons produced at 300 GeV π^- beam dump. The quoted bound assumes $\tilde{g}$-hadron nucleon total cross section of 10μb. See their figure 7 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ plane for several assumed total cross-section values.

[129] BARNETT 86 rule out light gluinos (m = 3–5 GeV) by calculating the monojet rate from gluino gluino gluon events (and from gluino gluino events) and by using UA1 data from $p\bar{p}$ collisions at CERN.

[130] VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron $\tilde{g}uud$. Quasi-stable ($\tau > 1. \times 10^{-7}$s) light gluino of $m_{\tilde{g}} < 3$ GeV is also ruled out by nonobservation of the stable charged particles, $\tilde{g}uud$, in high energy hadron collisions.

[131] COOPER-SARKAR 85B is BEBC beam-dump. Gluinos decaying in dump would yield $\tilde{\gamma}$'s in the detector giving neutral-current-like interactions. For $m_{\tilde{q}} > 330$ GeV, no limit is set.

[132] DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam dump experiment.

[133] FARRAR 85 points out that BALL 84 analysis applies only if the $\tilde{g}$'s decay before interacting, i.e. $m_{\tilde{q}} < 80 m_{\tilde{g}}^{1.5}$. FARRAR 85 finds $m_{\tilde{g}} < 0.5$ not excluded for $m_{\tilde{q}} = 30$–1000 GeV and $m_{\tilde{g}} < 1.0$ not excluded for $m_{\tilde{q}} = 100$–500 GeV by BALL 84 experiment.

[134] GOLDMAN 85 use nonobservation of a pseudoscalar $\tilde{g}$-$\tilde{g}$ bound state in radiative ψ decay.

[135] HABER 85 is based on survey of all previous searches sensitive to low mass $\tilde{g}$'s. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersymmetric particle.

[136] BALL 84 is FNAL beam dump experiment. Observed no interactions of $\tilde{\gamma}$ in the calorimeter, where $\tilde{\gamma}$'s are expected to come from pair-produced $\tilde{g}$'s. Search for long-lived $\tilde{\gamma}$ interacting in calorimeter 56m from target. Limit is for $m_{\tilde{q}} = 40$ GeV and production cross section proportional to $A^{0.72}$. BALL 84 find no $\tilde{g}$ allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on $m_{\tilde{q}}$ and A. See also KANE 82.

[137] BRICK 84 reanalyzed FNAL 147 GeV HBC data for R-$\Delta(1232)^{++}$ with $\tau > 10^{-9}$ s and $p_{lab} > 2$ GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in pp, $\pi^+ p$, $K^+ p$ collisions respectively. R-Δ^{++} is defined as being $\tilde{g}$ and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.

[138] FARRAR 84 argues that $m_{\tilde{g}} < 100$ MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than $\tilde{\gamma}$'s or if $m_{\tilde{q}} > 100$ GeV.

[139] BERGSMA 83C is reanalysis of CERN-SPS beam-dump data. See their figure 1.

[140] CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if $m_{\tilde{g}} < 1$ GeV. This is important since tracks from decay of neutral s-hadron cannot be reconstructed to primary vertex because of missed $\tilde{\gamma}$. Charged s-hadron leaves track from vertex.

[141] KANE 82 inferred above $\tilde{g}$ mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if $\tilde{g}$ decays inside detector.

Unstable $\tilde{\gamma}$ (Photino) MASS LIMIT

Unless stated otherwise, the limits below assume that the $\tilde{\gamma}$ decays either into $\gamma\tilde{G}$ (goldstino) or into $\gamma\tilde{H}^0$ (Higgsino).

		[145] ADEVA	85	MRKJ	
		[146] BALL	84	CALO	Beam dump
		[147] BARTEL	84B	JADE	
		[147] BEHREND	83	CELL	
		[148] CABIBBO	81	COSM	

[142] ACTON 93G assume R-parity violation and decays $\tilde{\gamma} \to \tau^\pm \ell^\mp \nu_\ell$ (ℓ= e or μ). They exclude $m_{\tilde{\gamma}}$ = 4–43 GeV for $m_{\tilde{e}_L} < 42$ GeV, and $m_{\tilde{\gamma}}$ = 7–30 GeV for $m_{\tilde{e}_L} < 100$ GeV (95% CL). Assumes $\tilde{e}_R$ much heavier than $\tilde{e}_L$, and lepton family number violation but L_e-L_μ conservation.

[143] ABE 89J exclude $m_{\tilde{\gamma}}$ = 0.15–25 GeV (95%CL) for $d = (100\ \text{GeV})^2$ and $m_{\tilde{e}} = 40$ GeV in the case $\tilde{\gamma} \to \gamma\tilde{G}$, and $m_{\tilde{\gamma}}$ up to 23 GeV for $m_{\tilde{e}} = 40$ GeV in the case $\tilde{\gamma} \to \gamma\tilde{H}^0$.

[144] BEHREND 87B limit is for unstable photinos only. Assumes B($\tilde{\gamma} \to \gamma(\tilde{G}$ or $\tilde{H}^0)$) =1, $m_{\tilde{G}\text{or}\tilde{H}^0} \ll m_{\tilde{\gamma}}$ and pure $\tilde{\gamma}$ eigenstate. $m_{\tilde{e}_L} = m_{\tilde{e}_R} < 100$ GeV.

[145] ADEVA 85 is sensitive to $\tilde{\gamma}$ decay path <5 cm. With $m_{\tilde{e}} = 50$ GeV, limit (CL = 90%) is $m_{\tilde{\gamma}} > 20.5$ GeV. Assume $\tilde{\gamma}$ decays to photon + goldstino and search for acoplanar photons with large missing p_T.

[146] BALL 84 is FNAL beam dump experiment. Observed no $\tilde{\gamma}$ decay, where $\tilde{\gamma}$'s are expected to come from $\tilde{g}$'s produced at the target. Three possible $\tilde{\gamma}$ lifetimes are considered. Gluino decay to goldstino + gluon is also considered.

[147] BEHREND 83 and BARTEL 84B look for 2γ events from $\tilde{\gamma}$ pair production. With supersymmetric breaking parameter $d = (100\ \text{GeV})^2$ and $m_{\tilde{e}} = 40$ GeV the excluded regions at CL = 95% would be $m_{\tilde{\gamma}}$ = 100 MeV – 13 GeV for BEHREND 83 $m_{\tilde{\gamma}}$ = 80 MeV – 18 GeV for BARTEL 84B. Limit is also applicable if the $\tilde{\gamma}$ decays radiatively within the detector.

[148] CABIBBO 81 consider $\tilde{\gamma} \to \gamma$ + goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

Supersymmetry Miscellaneous Results

Searches for Quark and Lepton Compositeness

NOTE ON SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ. The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2}\left[\eta_{LL}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_L\gamma^\mu\psi_L + \eta_{RR}\,\overline{\psi}_R\gamma_\mu\psi_R\,\overline{\psi}_R\gamma^\mu\psi_R + 2\eta_{LR}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_R\gamma^\mu\psi_R\right] . \quad (1)$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned}
&\Lambda = \Lambda^{\pm}_{LL} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, 0, 0) ,\\
&\Lambda = \Lambda^{\pm}_{RR} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm1, 0) ,\\
&\Lambda = \Lambda^{\pm}_{VV} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \pm1) ,\\
&\Lambda = \Lambda^{\pm}_{AA} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \mp1) , \quad (2)
\end{aligned}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, e.g., for $ee \to ee$) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for g–2 suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by SU(2)×U(1) quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L , \qquad [\nu^*_R] , \qquad \ell^*_R .$$

ν^*_R is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[\nu^*_L] , \qquad \ell^*_L , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R .$$

3. Homodoublet type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L , \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R .$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions" in Sec. III):

	Sequential type	Mirror type	Homodoublet type
V^{ℓ^*}	$-\frac{1}{2}+2\sin^2\theta_W$	$-\frac{1}{2}+2\sin^2\theta_W$	$-1+2\sin^2\theta_W$
A^{ℓ^*}	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{\nu^*_D}$	$+\frac{1}{2}$	$+\frac{1}{2}$	+1
$A^{\nu^*_D}$	$+\frac{1}{2}$	$-\frac{1}{2}$	0
$V^{\nu^*_M}$	0	0	—
$A^{\nu^*_M}$	+1	−1	—

Here ν^*_D (ν^*_M) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parametrized as follows:

$$\begin{aligned}
\mathcal{L} = {}& \frac{\lambda^{(f^*)}_\gamma e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f F_{\mu\nu}\\
&+\frac{\lambda^{(f^*)}_Z e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f Z_{\mu\nu}\\
&+\frac{\lambda^{(\ell^*)}_W g}{2m_{\ell^*}}\,\overline{\ell}^*\sigma^{\mu\nu}\tfrac{1-\gamma_5}{2}\nu W_{\mu\nu}\\
&+\frac{\lambda^{(\nu^*)}_W g}{2m_{\nu^*}}\,\overline{\nu}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})\ell W^\dagger_{\mu\nu}\\
&+\text{h.c.} , \quad (3)
\end{aligned}$$

where $g = e/\sin\theta_W$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.* The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1 .$$

Chirality conservation requires

$$\eta_L \eta_R = 0 \,. \tag{4}$$

These couplings can arise from SU(2)×U(1)-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda}\overline{L}^*(gf\tfrac{\tau^a}{2}W^a_{\mu\nu} + g'f'YB_{\mu\nu})\tfrac{1-\gamma_5}{2}L + \text{h.c.}\,, \tag{5}$$

where L denotes the lepton doublet (ν, ℓ), Λ is the compositeness scale, g, g' are SU(2) and U(1)$_Y$ gauge couplings, and $W^a_{\mu\nu}$ and $B_{\mu\nu}$ are the field strengths for SU(2) and U(1)$_Y$ gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of $(250\,\text{GeV})/\Lambda$ or m_{L^*}/Λ. In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z \cot\theta_W + \lambda_\gamma)\,. \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\mathcal{L} = \frac{1}{2\Lambda}\overline{Q}^*\sigma^{\mu\nu}\left(g_s f_s \tfrac{\lambda^a}{2}G^a_{\mu\nu} + g\,f\tfrac{\tau^a}{2}W^a_{\mu\nu} + g'\,f'YB_{\mu\nu}\right) \times \tfrac{1-\gamma_5}{2}Q + \text{h.c.}\,, \tag{7}$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G^a_{\mu\nu}$ the gluon field strength.

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1,0)$ or $(0,1)$ after rescaling λ.

Several different conventions are used by LEP experiments to express the transition magnetic couplings. To facilitate comparison, we reexpress these in terms of λ_Z and λ_γ using the following relations and taking $\sin^2\theta_W = 0.23$. We assume chiral couplings, *i.e.*, $|c| = |d|$ in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2}\lambda_Z \quad (1990\text{ papers}) \tag{8a}$$

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}[\text{or } m_{\nu^*}]} \quad (\text{for } |c| = |d|) \tag{8b}$$

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin\theta_W\cos\theta_W}{\sqrt{\frac{1}{4} - \frac{2}{3}\sin^2\theta_W + \frac{8}{9}\sin^4\theta_W}}\lambda_Z = 1.11\lambda_Z \tag{9}$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot\theta_W - \tan\theta_W}\lambda_Z = -1.10\lambda_Z \tag{10}$$

4. L3 (neutrino)

$$f_Z^{\text{L3}} = \sqrt{2}\lambda_Z \tag{11}$$

5. OPAL (charged lepton)

$$\frac{f^{\text{OPAL}}}{\Lambda} = -\frac{2}{\cot\theta_W - \tan\theta_W}\frac{\lambda_Z}{m_{\ell^*}} = -1.56\frac{\lambda_Z}{m_{\ell^*}} \tag{12}$$

6. OPAL (quark)

$$\frac{f^{\text{OPAL}}{}_c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|) \tag{13}$$

7. DELPHI (charged lepton)

$$\lambda_\gamma^{\text{DELPHI}} = -\frac{1}{\sqrt{2}}\lambda_\gamma \tag{14}$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda}\sum_\ell \left\{\overline{\ell}^\alpha_8\, g_S\, F^\alpha_{\mu\nu}\,\sigma^{\mu\nu}\left(\eta_L\,\ell_L + \eta_R\,\ell_R\right) + h.c.\right\} \tag{15}$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L\,\eta_R = 0$ as before.

[9] This BUSKULIC 93Q value is from ALEPH data plus PEP/PETRA/TRISTAN data re-analyzed by KROHA 92.

[10] BUSKULIC 93Q uses the following prescription to obtain the limit: when the naive 95%CL limit is better than the statistically expected sensitivity for the limit, the latter is adopted for the limit.

[11] KROHA 92 limit is from fit to BARTEL 86C, BEHREND 87C, BRAUNSCHWEIG 88D, BRAUNSCHWEIG 89C, ABE 90I, and BEHREND 91C. The fit gives $\eta/\Lambda^2_{LL} = -0.155 \pm 0.095$ TeV^{-2}.

[12] ABE 90I assumed m_Z =91.163 GeV and $\sin^2\theta_W = 0.231$.

[13] BARTEL 86C assumed m_Z = 93 GeV and $\sin^2\theta_W = 0.217$.

[14] BERGER 85 assumed m_Z = 93 GeV and $\sin^2\theta_W = 0.217$.

SCALE LIMITS for Contact Interactions: $\Lambda(ee\tau\tau)$

Limits are for $\Lambda^{\pm}_{LL}$ only. For other cases, see each reference.

>6.5		[33] DIAZCRUZ	94	RVUE	$\Lambda^{-}_{LL}(\tau\nu_\tau\mu\nu_\mu)$

[31] JODIDIO 86 limit is from $\mu^+ \to \bar{\nu}_\mu e^+\nu_e$. Chirality invariant interactions $L = (g^2/\Lambda^2)$ $[\eta_{LL}\,(\bar{\nu}_{\mu L}\gamma^\alpha\mu_L)\,(\bar{e}_L\gamma_\alpha\nu_{eL}) + \eta_{LR}\,(\bar{\nu}_{\mu L}\gamma^\alpha\nu_{eL}\,(\bar{e}_R\gamma_\alpha\mu_R)]$ with $g^2/4\pi = 1$ and $(\eta_{LL},\eta_{LR}) = (0,\pm1)$ are taken. No limits are given for $\Lambda^{\pm}_{LL}$ with $(\eta_{LL},\eta_{LR}) = (\pm1,0)$. For more general constraints with right-handed neutrinos and chirality nonconserving contact interactions, see their text.

[32] DIAZCRUZ 94 limits are from $\Gamma(\tau \to e\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau e\nu_e) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

[33] DIAZCRUZ 94 limits are from $\Gamma(\tau \to \mu\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau\mu\nu_\mu) \ll \Lambda(\mu\nu_\mu e\nu_e)$.

SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$

Limits are for $\Lambda^{\pm}_{LL}$ with color-singlet isoscalar exchanges among u_L's and d_L's only. See EICHTEN 84 for details.

>0.400	95	[39] ARNISON	86C	UA1	$p\bar{p} \to$ jets inclusive
>0.415	95	[40] ARNISON	86D	UA1	$p\bar{p} \to$ dijet angl.
>0.370	95	[41] APPEL	85	UA2	$p\bar{p} \to$ jets inclusive
>0.275	95	[42] BAGNAIA	84C	UA2	Repl. by APPEL 85

[34] Limit is from inclusive jet cross-section data in $p\bar{p}$ collisions at E_{cm} = 1.8 TeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.

[35] ABE 93G limit is from dijet mass distribution in $p\bar{p}$ collisions at E_{cm} = 1.8 TeV. The limit is the weakest from several choices of structure functions and renormalization scale.

[36] ABE 92M limit is from dijet angular distribution for m_{dijet} >550 GeV in $p\bar{p}$ collisions at E_{cm}=1.8 TeV.

[37] ALITTI 91B limit is from inclusive jet cross section in $p\bar{p}$ collisions at E_{cm} = 630 GeV. The limit takes into account uncertainties in choice of structure functions and in choice of process scale.

[38] ABE 89H limit is from dijet angular distribution for m_{dijet} > 200 GeV at the Fermilab Tevatron Collider with E_{cm} = 1.8 TeV. The QCD prediction is quite insensitive to choice of structure functions and choice of process scale.

[39] ARNISON 86C limit is from the study of inclusive high-p_T jet distributions at the CERN $\bar{p}p$ collider (E_{cm} = 546 and 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good fit to the data.

[40] ARNISON 86D limit is from the study of dijet angular distribution in the range 240 < m(dijet) < 300 GeV at the CERN $\bar{p}p$ collider (E_{cm} = 630 GeV). QCD prediction using EHLQ structure function (EICHTEN 84) with Λ_{QCD} = 0.2 GeV for the choice of $Q^2 = p_T{}^2$ gives the best fit to the data.

[41] APPEL 85 limit is from the study of inclusive high-p_T jet distributions at the CERN $\bar{p}p$ collider (E_{cm} = 630 GeV). The QCD prediction renormalized to the low-p_T region gives a good description of the data.

[42] BAGNAIA 84C limit is from the study of jet p_T and dijet mass distributions at the CERN $\bar{p}p$ collider (E_{cm} = 540 GeV). The limit suffers from the uncertainties in comparing the data with the QCD prediction.

MASS LIMITS for Excited e (e^*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e^*) from Pair Production

These limits are obtained from $e^+e^- \to e^{*+}e^{*-}$ and thus rely only on the (electroweak) charge of e^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume $e^* \to e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45,** 1 June, Part II (1992)).

[54] BUSKULIC 93Q obtain $\Lambda^+ > 121$ GeV (95%CL) from ALEPH experiment and $\Lambda^+ > 135$ GeV from combined TRISTAN and ALEPH data. These limits roughly correspond to limits on m_{e^*}.
[55] BARDADIN-OTWINOWSKA 92 limit from fit to the combined data of DECAMP 92, ABREU 91E, ADEVA 90K, AKRAWY 91F.
[56] SHIMOZAWA 92 fit the data to the limiting form of the cross section with $m_{e^*} \gg E_{cm}$ and obtain $m_{e^*} > 168$ GeV at 95%CL. Use of the full form would reduce this limit by a few GeV. The statistically unexpected large value is due to fluctuation in the data.
[57] The ABE 89J limit assumes chiral coupling. This corresponds to $\lambda_\gamma = 0.7$ for nonchiral coupling.

Indirect Limits for Excited e (e^*)

These limits make use of loop effects involving e^* and are therefore subject to theoretical uncertainty.

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[58] DORENBOS...	89	CHRM	$\bar{\nu}_\mu e \to \bar{\nu}_\mu e$ and $\nu_\mu e \to \nu_\mu e$
	[59] GRIFOLS	86	THEO	$\nu_\mu e \to \nu_\mu e$
	[60] RENARD	82	THEO	$g-2$ of electron

[58] DORENBOSCH 89 obtain the limit $\lambda_\gamma^2 \Lambda_{cut}^2 / m_{e^*}^2 < 2.6$ (95% CL), where Λ_{cut} is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that Λ_{cut} = 1 TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*}/\Lambda_{cut}$ in composite models.
[59] GRIFOLS 86 uses $\nu_\mu e \to \nu_\mu e$ and $\bar{\nu}_\mu e \to \bar{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.
[60] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \to \mu^{*+}\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume $\mu^* \to \mu\gamma$ decay except for the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45,** 1 June, Part II (1992)).

	[67] RENARD	82	THEO	$g-2$ of muon

[67] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited τ (τ^*)

Limits for Excited τ (τ^*) from Pair Production

These limits are obtained from $e^+e^- \to \tau^{*+}\tau^{*-}$ and thus rely only on the (electroweak) charge of τ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the τ^* coupling is assumed to be of sequential type. All limits assume $\tau^* \to \tau\gamma$ decay except for the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45,** 1 June, Part II (1992)).

[68] BARDADIN-OTWINOWSKA 92 limit is independent of decay modes. Based on $\Delta\Gamma(Z)$<36 MeV.
[69] Limit is independent of τ^* decay mode.
[70] Superseded by ADRIANI 93M.
[71] Superseded by DECAMP 92.

Limits for Excited τ (τ^*) from Single Production

These limits are from $e^+e^- \to \tau^*\tau$ and depend on transition magnetic coupling between τ and τ^*. All limits assume $\tau^* \to \tau\gamma$ decay. Limits from LEP are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the $\lambda - m_{\tau^*}$ plane. See the original papers.

[74] BARTEL 86 is at E_{cm} = 30–46.78 GeV.
[75] BEHREND 86 limit is at E_{cm} = 33–46.8 GeV.

MASS LIMITS for Excited Neutrino (ν^*)

Limits for Excited ν (ν^*) from Pair Production

These limits are obtained from $Z \to \nu^*\nu^*$ decay and thus rely only on the (electroweak) charge of ν^*. Form factor effects are ignored unless noted. The ν^* coupling is assumed to be of sequential type. Limits assume $\nu^* \to \nu\gamma$ decay except for the $\Gamma(Z)$ measurement which makes no assumption about decay mode.

[95] ABE 94 search for resonances in jet-γ and jet-W invariant mass in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$ and u^* and d^* are assumed to be degenerate. See their Fig. 4 for the excluded region in m_{q^*}-f plane.

[96] ALITTI 93 search for resonances in the two-jet invariant mass. The limit is for $f_s = f = f' = \Lambda/m_{q^*}$. u^* and d^* are assumed to be degenerate. If not, the limit for u^* (d^*) is 277 (247) GeV if $m_{d^*} \gg m_{u^*}$ ($m_{u^*} \gg m_{d^*}$).

[97] Assumes $B(q^* \to q\gamma) = 0.1$.

[98] Assumes $B(q^* \to qg) = 1$.

[99] ABREU 92D give $\sigma(e^+e^- \to Z \to q^*\bar{q}$ or $q\bar{q}^*) \times B(q^* \to q\gamma) < 15$ pb (95% CL) for $m_{q^*} < 80$ GeV.

[100] ADRIANI 92F search for $Z \to qq^*$ with $q^* \to q\gamma$ and give the limit $\sigma_Z \cdot B(Z \to qq^*) \cdot B(q^* \to q\gamma) < (2$–$10)$ pb (95%CL) for $m_{q^*} = (46$–$82)$ GeV.

[101] ALBAJAR 89 give $\sigma(q^* \to W + \text{jet})/\sigma(W) < 0.019$ (90% CL) for $m_{q^*} > 220$ GeV.

[102] BEHREND 86C has $E_{cm} = 42.5$–46.8 GeV. See their Fig. 3 for excluded region in the m_{q^*}–$(\lambda_\gamma/m_{q^*})^2$ plane. The limit is for $\lambda_\gamma = 1$ with $\eta_L = \eta_R = 1$.

MASS LIMITS for Color Sextet Quarks (q_6)

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>84	95	[103] ABE	89D	CDF	$p\bar{p} \to q_6\bar{q}_6$

[103] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color sextet quark is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. A limit of 121 GeV is obtained for a color decuplet.

MASS LIMITS for Color Octet Charged Leptons (ℓ_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT

>19.8	95	[108] BARTEL	87B	JADE	e_8, μ_8, τ_8: e^+e^-; R
none 5–23.2	95	[108] BARTEL	87B	JADE	μ_8: $e^+e^- \to \mu\mu +$ jets
		[109] BARTEL	85K	JADE	e_8: $e^+e^- \to gg$; R

[104] ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments into a unit-charged hadron.

[105] ABT 93 search for e_8 production via e-gluon fusion in ep collisions with $e_8 \to eg$. See their Fig. 3 for exclusion plot in the m_{e_8}–Λ plane for $m_{e_8} = 35$–220 GeV.

[106] KIM 90 is at $E_{cm} = 50$–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[107] KIM 90 result $(m_{e_8}\Lambda_M)^{1/2} > 178.4$ GeV (95%CL, $\alpha_s = 0.16$ used) is subject to the same restriction as for BARTEL 85K.

[108] BARTEL 87B is at $E_{cm} = 46.3$–46.78 GeV. The limits assume ℓ_8 pair production cross sections to be eight times larger than those of the corresponding heavy lepton pair production.

[109] In BARTEL 85K, R can be affected by $e^+e^- \to gg$ via e_q exchange. Their limit $m_{e_8} > 173$ GeV (CL=95%) at $\lambda = m_{e_8}/\Lambda_M = 1$ ($\eta_L = \eta_R = 1$) is not listed above because the cross section is sensitive to the product $\eta_L\eta_R$, which should be absent in ordinary theory with electronic chiral invariance.

MASS LIMITS for Color Octet Neutrinos (ν_8)

$\lambda \equiv m_{\ell_8}/\Lambda$

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>110	90	[110] BARGER	89	RVUE	ν_8: $p\bar{p} \to \nu_8\bar{\nu}_8$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 3.8–29.8	95	[111] KIM	90	AMY	ν_8: $e^+e^- \to$ acoplanar jets
none 9–21.9	95	[112] BARTEL	87B	JADE	ν_8: $e^+e^- \to$ acoplanar jets

[110] BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_8 \to \nu g$ is assumed.

[111] KIM 90 is at $E_{cm} = 50$–60.8 GeV. The same assumptions as in BARTEL 87B are used.

[112] BARTEL 87B is at $E_{cm} = 46.3$–46.78 GeV. The limit assumes the ν_8 pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its $SU(2)_L \times U(1)_Y$ quantum numbers.

MASS LIMITS for W_8 (Color Octet W Boson)

Other Stable Particle Searches

OMITTED FROM SUMMARY TABLE

NOTE ON OTHER STABLE PARTICLE SEARCHES

We collect here those searches which do not appear in any of the above search categories. These include heavy particle searches in accelerator experiments, in cosmic rays, and in matter. Searches are also listed for light particles, highly ionizing particles, penetrating non-neutrino-like particles, and tachyons. Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks and monopoles, supersymmetry, and compositeness.

Centauro Production Cross Section in Accelerator Experiments

VALUE (cm^2)	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$<0.005\sigma$ (nondiff.)	95	0	[1] ALNER	86	UA5	$p\bar{p}$ collider
$<1. \times 10^{-30}$		0	[2] ARNISON	83B	UA1	$p\bar{p}$ collider
		0	[3] ALPGARD	82	UA5	$p\bar{p}$ collider

[1] ALNER 86 is CERN collider experiment at $W_{cm} = 900$ GeV. Looked for high multiplicity, low EM content in measured high p_T events from an unbiased sample of 5500 events. No candidates observed.

[2] ARNISON 83B is CERN collider experiment with $W_{cm} = 540$ GeV. Looked for events with large hadronic and low electromagnetic content. None in 48000 low bias events.

[3] ALPGARD 82 is CERN collider experiment with $W_{cm} = 540$ GeV (155 TeV lab equivalent). Observed no large charged multiplicity events with photon multiplicity consistent with zero in 3600 inelastic events.

Centauro Production in Cosmic Ray Interactions

A Centauro event is characterized by a hadronic event with high multiplicity, high mean p_T, and unusually small photon energy.

VALUE	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.03	95	0	[4] REN	88	EMUL	e(shower) > 100 TeV
		1	BORISOV	87	EMUL	
			BAYBURINA	81	EMUL	
			LATTES	80	EMUL	

[4] REN 88 limit is for the fraction of Centauro events in the sample of hadronic showers with energy exceeding 100 TeV. No candidates were observed despite a total exposure exceeding that of previous experiments.

Light (between μ and e Masses) Particle MASS

VALUE (m_e)	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 110–180	0	[5] VIERTEL	78	CNTR	$\tau > 2. \times 10^{-5}$ s
none 2–13	0	[6] BLAGOV	75	CNTR	Spinor, $\tau > 2 \times 10^{-10}$ s
none 2–10.6	0	[6] BLAGOV	75	CNTR	Scalar, $\tau > 2 \times 10^{-10}$ s
none 5–175	0	COWARD	63	CNTR	Spinor, $\tau > 22 \times 10^{-10}$
none 5–175	0	COWARD	63	CNTR	Scalar, $\tau > 68 \times 10^{-10}$
none 6–25	0	BELOUSOV	60	CNTR	Spinor, $\tau > 1 \times 10^{-8}$
none 2–25	0	GORBUNOV	60	CC	Spinor, $\tau > 1 \times 10^{-9}$

[5] VIERTEL 78 searches for $\mu^+ \to X^+\nu$. Finds BR $< 8.5 \times 10^{-6}$ in mass range given above (CL = 90%). Best limit BR $< 5. \times 10^{-7}$ (CL = 90%) is found at mass = 80 MeV.

[6] BLAGOV 75 bounds on lifetime depend on mass and improve as mass decreases. At 2 GeV the experiment is sensitive to $\tau > 3 \times 10^{-11}$ s for spinor, $\tau > 5 \times 10^{-11}$ s for scalar.

Highly Ionizing Particle Flux

Tachyon Flux in Cosmic Rays

See SMITH 77 for a review of earlier cosmic ray and accelerator experiments.

VALUE ($cm^{-2}sr^{-1}s^{-1}$)	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$<2.4 \times 10^{-9}$	90	0	[7] MARINI	82	CNTR	$v/c>1.2$
$<2.3 \times 10^{-10}$	95	0	[8] BHAT	79	CNTR	
			[9] SMITH	77	CNTR	
			[10] PRESCOTT	76	CNTR	

[7] MARINI 82 is TOF measurement using PEP-counter at sea level.

[8] BHAT 79 is at Ootacamund (2200m above sea). No signal in 3621 hours.

[9] SMITH 77 analyzed more than 200000 showers (223 days) with $E > 10^{14}$ eV scanning 290×10^{-6} s period before each shower. Observed excess 46 ± 40 events does not constitute statistically significant evidence.

[10] PRESCOTT 76 reanalyzed Clay and Crouch('C.C.') 74 data (Nature **248** 28 (1974)). Found apparatus effect, correction for which much reduces the statistical significance of positive 'C.C.' result. Also performed two new experiments one using 'C.C.' apparatus, another with new apparatus. Set upper limit at CL = 95% of about 30 tachyons per shower with average size $N = 6 \times 10^5$.

Tachyon Searches in e^+e^- Annihilation

VALUE	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$<1. \times 10^{-6}$	90	0	[11] PEREPELITSA 77		CNTR	uv_{eq} <1
$<1. \times 10^{-5}$	90	0	[11] PEREPELITSA 77		CNTR	$1 < uv_{eq} < 15$

[11] PEREPELITSA 77 is Michelson-type experiment for pair-produced tachyons in e^+e^- annihilation (e^+ from Cu isotope). Above limits are for $\sigma(e^+e^- \to$ tachyon pair$)/\sigma(e^+e^- \to 2\gamma)$ and uv_{eq} is tachyon velocities times earth equator component of velocity of preferred reference frame.

Searches for Tachyonic Decay (lower limit for mean life)

$<5.0 \times 10^{-2}$	90	0	[18] BARTEL	80	JADE	Q=(3,4,5)/3 2–12 GeV

[14] BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.

[15] ADACHI 90C is a KEK-TRISTAN experiment with W_{cm} = 52–60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.

[16] ADACHI 90E is KEK-TRISTAN experiment with W_{cm} = 52–61.4 GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \to \mu^+\mu^-)\cdot\beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W_{cm}^2)^{1/2}$. See the paper for the assumption about the production mechanism.

[17] KINOSHITA 82 is SLAC PEP experiment at W_{cm} = 29 GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.

[18] BARTEL 80 is DESY-PETRA experiment with W_{cm} = 27–35 GeV. Above limit is for inclusive pair production and ranges between $1. \times 10^{-1}$ and $1. \times 10^{-2}$ depending on mass and production momentum distributions. (See their figures 9, 10, 11).

Heavy Particle Production Cross Section in $p\bar{p}$

Limits are for a particle decaying to two hadronic jets.

Units(pb)	CL%	Mass(GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •

<30–130			[21] CARROLL	78	SPEC	m=2–2.5 GeV
<100		0	[22] LEIPUNER	73	CNTR	m=3–11 GeV

[20] ABE 92J look for pair production of unit-charged particles which leave detector before decaying. Limit shown here is for m=50 GeV. See their Fig. 5 for different charges and stronger limits for higher mass.

[21] CARROLL 78 look for neutral, $S = -2$ dihyperon resonance in $pp \to 2K^+X$. Cross section varies within above limits over mass range and p_{lab} = 5.1–5.9 GeV/c.

[22] LEIPUNER 73 is an NAL 300 GeV p experiment. Would have detected particles with lifetime greater than 200 ns.

Heavy Particle Production Cross Section

VALUE (cm^2/N)	CL%	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •							
$<(4–0.3)\times 10^{-31}$	95		[23] AKESSON	91	CNTR	0	m = 0–5 GeV
$<2.5 \times 10^{-35}$		0	[24] GUSTAFSON	76	CNTR	0	$\tau > 10^{-7}$ s

[23] AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7}$ s. For $\tau > 10^{-9}$ s, $\sigma < 10^{-30}$ cm^{-2}/nucleon is obtained.

[24] GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy (m >2 GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for m = 3 GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

$<3.0 \times 10^{-36}$		0	[32] DORFAN	65	CNTR		Fe target m=3–7 GeV

[25] BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at $\theta = 0$. For other charges in range −0.5 to −3.0, CL = 90% limit is $(2.6 \times 10^{-36})/|(\text{charge})|$ for mass range (2.1–9.4 GeV) × |(charge)|. Assumes stable particle interacting with matter as do antiprotons.

[26] ALBROW 75 is a CERN ISR experiment with E_{cm} = 53 GeV. θ = 40 mr. See figure 5 for mass ranges up to 35 GeV.

[27] JOVANOVICH 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges Q = 1/3 to 2 and m = 3 to 26 GeV. Value is per GeV momentum.

[28] APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24–200 GeV (−charge) and 40–150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

[29] ALPER 73 is CERN ISR 26+26 GeV pp experiment. p >0.9 GeV, 0.2 < β <0.65.

[30] ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

[31] ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

[32] DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

VALUE ($cm^2/GeV^2/N$)	CL%	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •

$<3.0 \times 10^{-37}$	90	0	[38] VIDAL	78	CNTR		m=4.5–6 GeV

[33] BERNSTEIN 88 limits apply at x = 0.2 and p_T = 0. Mass and lifetime dependence of limits are shown in the regions: m = 1.5–7.5 GeV and $\tau = 10^{-8}$–2×10^{-6} s. First number is for hadrons; second is for weakly interacting particles.

[34] THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3 \times 10^{-9}$ s.

[35] ARMITAGE 79 is CERN-ISR experiment at E_{cm} = 53 GeV. Value is for x = 0.1 and p_T = 0.15. Observed particles at m = 1.87 GeV are found all consistent with being antideuterons.

[36] BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11–18 for production cross-section upper limits vs mass.

[37] CUTTS 78 is pBe experiment at FNAL sensitive to particles of $\tau > 5 \times 10^{-8}$ s. Value is for −0.3 <x <0 and p_T = 0.175.

[38] VIDAL 78 is FNAL 400 GeV proton experiment. Value is for x = 0 and p_T = 0. Puts lifetime limit of $< 5 \times 10^{-8}$ s on particle in this mass range.

Long-Lived Heavy Particle Production (σ(Heavy Particle) / $\sigma(\pi)$)

[42] FRANKEL 75 is extension of FRANKEL 74.

[43] FRANKEL 74 looks for particles produced in thick Al targets by 300–400 GeV/c protons.

[44] ASTONE 93 searched for quark matter ("nuclearites") in the velocity/c range $= 10^{-3}$–1. Their Table 1 gives a compilation of searches for nuclearites.

[45] AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity/c $< 2.5 \times 10^{-3}$. See their Fig. 3 for other velocity/c and heavier mass range.

[46] SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.

[47] MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.

[48] NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity/c of 10^{-4}–10^{-3}.

[49] SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.

[50] BHAT 82 observed 12 events with delay $> 2. \times 10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.

[51] MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.

[52] ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.

[53] YOCK 81 saw another 3 events with $Q = \pm 1$ and m about $4.5 m_p$ as well as 2 events with $m > 5.3 m_p$, $Q = \pm 0.75 \pm 0.05$ and $m > 2.8 m_p$, $Q = \pm 0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3.) m_p$, $Q = \pm 0.89 \pm 0.06$ as possible heavy candidates.

[54] YOCK 80 events are with charge exactly or approximately equal to unity.

[55] BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.

[56] YOCK 74 events could be tritons.

Concentration of Heavy (Charge +1) Stable Particles In Matter

[57] YAMAGATA 93 used deep sea water at 4000 m since the concentration is enhanced in deep sea due to gravity.

[58] VERKERK 92 looked for heavy isotopes in sea water and put a bound on concentration of stable charged massive particle in sea water. The above bound can be translated into into a bound on charged dark matter particle (5×10^6 GeV), assuming the local density, ρ=0.3 GeV/cm^3, and the mean velocity $\langle v \rangle$=300 km/s.

[59] See HEMMICK 90 Fig. 7 for other masses 100–10000 m_p.

through the

AMERICAN INSTITUTE OF PHYSICS

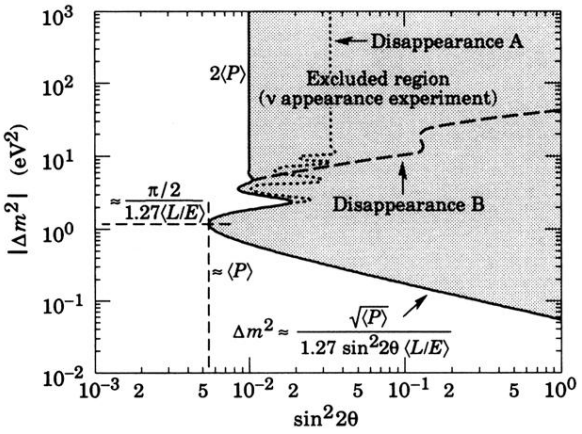

Figure 1: Neutrino oscillation parameter ranges excluded by a toy experiment in which one searches for the appearance of neutrinos not expected in the beam. The probability of appearance, in this case 0.5% at some specified CL, is set by the number of right-flavor events observed and/or information about the flux and cross sections. Here it is assumed that $\langle L/E \rangle = 1$ km GeV^{-1}, and that the distribution of L/E is Gaussian with a 20% standard deviation. The wiggle structure is determined by the resolution function, and the intercepts are determined by the appearance probability and $\langle L/E \rangle$. The leftmost excursion relative to the high-$|\Delta m^2|$ limit and the slope of the lower part of the curve are independent of the experiment. In a disappearance experiment, high-$|\Delta m^2|$ sensitivity is lost unless the incident flux is known. These two possibilities are shown qualitatively by the dashed lines marked "Disappearance A" and "Disappearance B."

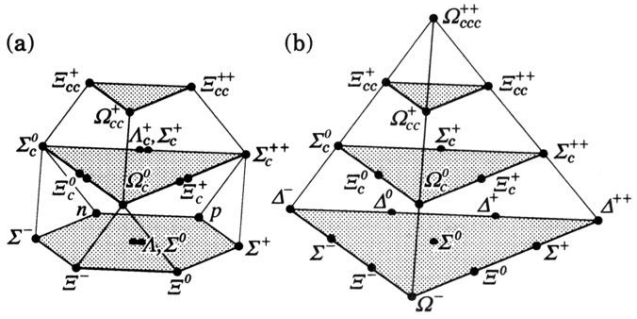

Fig. 1. SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet on the "ground floor." (b) The 20-plet with an SU(3) decuplet on the ground floor.
