Abstract

This biennial review summarizes much of Particle Physics. Using data from previous editions, plus 2300 new measurements from 700 papers, we list, evaluate, and average measured properties of gauge bosons, leptons, quarks, mesons, and baryons. We also summarize searches for hypothetical particles such as Higgs bosons, heavy neutrinos, monopoles, and supersymmetric particles. All the particle properties and search limits are listed in Summary Tables. We also give numerous tables, figures, formulae, and reviews of topics such as the Standard Model, particle detectors, probability, and statistics. A booklet is available containing the Summary Tables and abbreviated versions of some of the other sections of this full *Review*.

†The publication of the *Review of Particle Properties* is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE–AC03–76SF00098, and by the U.S. National Science Foundation under Agreement No. PHY-9320551. Partial funding to cover the cost of this *Review* is also provided by the European Laboratory for Particle Physics (CERN), the Italian National Institute of Nuclear Physics (INFN), and by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development.

INTRODUCTION

1. Overview

The *Review of Particle Properties* and the abbreviated version, the *Particle Physics Booklet,* are reviews of the field of Particle Physics. This complete *Review* includes a compilation/evaluation of data on particle properties, called the "Full Listings." These Listings include 2300 new measurements from 700 papers, in addition to the 12,000 measurements from 3500 papers that first appeared in previous editions. Both books include Summary Tables with our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as reviews, tables, and figures on a variety of topics. We also give an extensive summary of searches for hypothetical particles.

The *Review* and the *Booklet* are published in even-numbered years. This edition is an updating through December 1993 (and, in some areas, well into 1994). As described in the section "Using Particle Physics Databases" following this introduction, the content of this *Review* is available on the World-Wide Web, and there is a public access database allowing user-designed searches.

The Summary Tables give our best values of the properties of the particles we consider to be well established, a summary of search limits for hypothetical particles, and a summary of experimental tests of conservation laws.

The Full Listings contain all the data used to get the values given in the Summary Tables. Other measurements considered recent enough or important enough to mention, but which for one reason or another are not used to get the best values, appear separately just beneath the data we do use for the Summary Tables. The Full Listings also give information on unconfirmed particles and on particle searches, as well as short "minireviews" on subjects of particular interest or controversy.

The Full Listings were once an archive of all published data on particle properties. This is no longer possible because of the large quantity of data. We refer interested readers to earlier editions for data now considered to be obsolete.

We organize the particles into five categories:

Gauge and Higgs bosons
Leptons and quarks
Mesons
Baryons
Searches for free quarks, monopoles, supersymmetry, compositeness, *etc.*

The last category is for searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, for example, are with the leptons.

In addition to the compilations of measurements and best values, we give a long section of "Reviews, Tables, and Plots," a quick reference for the practicing particle physicist.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors, and also list our large number of consultants, without whom we would not have been able to produce this *Review.* In Sec. 3, we mention briefly the naming scheme for hadrons. In Sec. 4, we discuss our procedures for choosing among measurements of particle properties and for obtaining best values of the properties from the measurements.

The accuracy and usefulness of this *Review* depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to

Particle Data Group, MS 50–308
Lawrence Berkeley Laboratory
Berkeley, CA 94720, USA

Or send them via computer mail to

PDG@LBL.GOV on INTERNET or
LBL::PDG on HEPNET, or
PDG@LBL on BITNET.

To order a copy of the *Review* or the *Particle Physics Booklet* from North and South America, Australia, and the Far East, write to

Particle Data Group, MS 50-308
Lawrence Berkeley Laboratory

- B.N. Taylor (NIST)

In addition, the Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review*. Of special value is the advice of the PDG Advisory Committee which meets annually and thoroughly reviews all aspects of our operation. The members of the 1993 committee were:

W. Toki (Colorado State University), Chair
D. Schaile (CERN)
P. Kreitz (SLAC)
P. Langacker (University of Pennsylvania)
M. Turner (Fermilab)

3. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the $F^{\pm}$ became the $D_s^{\pm}$. None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 1323) of this *Review*.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^-, p, Λ, π^0, K_L, D_s^+, b. Charge is indicated by a superscript: B^-, Δ^{++}. Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0. Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+, K^-. Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, $\overline{t}$, $\overline{p}$, $\overline{K}^0$, and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

4. Procedures

4.1. ***Selection and treatment of data***: The Full Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Full Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.
- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion, which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, *none* of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Full Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Full Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data.
- OUR FIT—From a constrained or overdetermined multi-parameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Full Listings all reported

states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Full Listings.

4.2. *Averages and fits*: We divide this discussion on obtaining averages and errors into three sections: (1) treatment of errors; (2) unconstrained averaging; (3) constrained fits.

4.2.1. *Treatment of errors:* In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error *is* Gaussian, δx is the usual one standard deviation (1σ). Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the the two errors in quadrature and use this combined error for δx.

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit $\overline{x}$ is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ. In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ. One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum (1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i, each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, *e.g.*, m_1, m_2, and $\Delta = m_2 - m_1$. We cannot enter all of m_1, m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1, m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

4.2.2. *Unconstrained averaging:* To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta\overline{x} = \frac{\sum_i w_i\, x_i}{\sum_i w_i} \pm \left(\sum_i w_i\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2 .$$

Here x_i and δx_i are the value and error reported by the ith experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with $N-1$, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta\overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2/(N-1)\right]^{1/2} . \qquad (2)$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes $N-1$, and of course the output error $\delta\overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2}\,\delta\overline{x} ,$$

where $\delta\overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values $\overline{x}$ and $\delta\overline{x}$, they can make significant contributions to the χ^2, and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i, then $\delta\overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta\overline{x}$ is

approximately half the interval between the two discrepant values.

We emphasize that our scaling procedure for *errors* in no way affects central values. And if you wish to recover the unscaled error $\delta\overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Full Listings an ideogram of the data. Fig. 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

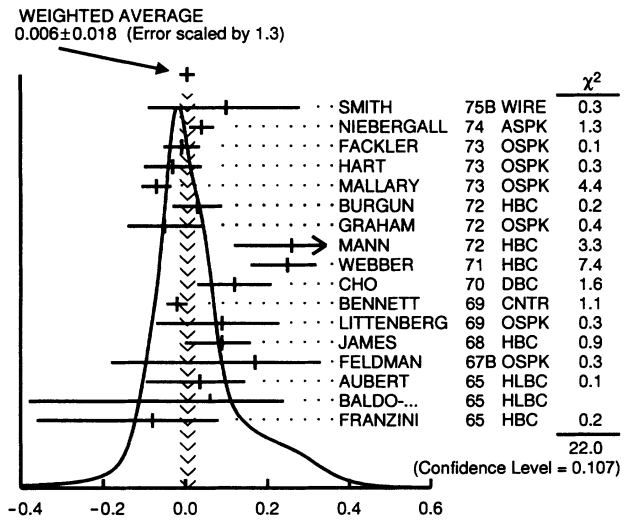

Figure 1: A typical ideogram. The "data point" at the top shows the position of the weighted average, while the width of the error bar (and the shaded pattern beneath it) shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag ($\perp$), is not used in the calculation of S (see the text).

Each measurement in an ideogram is represented by a Gaussian with a central value x_i, error δx_i, and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

4.2.3. *Constrained fits:* Except for trivial cases, all branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i, the partial widths Γ_i, the full width Γ (or mean life), and the associated error matrix.

Assume, for example, that a state has m partial decay fractions P_i, where $\sum P_i = 1$. These have been measured in N_r different ratios R_r, where, e.g., $R_1 = P_1/P_2$, $R_2 = P_1/P_3$, *etc.* [We can handle any ratio R of the form $\sum \alpha_i P_i / \sum \beta_i P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_iP_j$ and $R = (P_iP_j)^{1/2}$ are also allowed.] Further assume that *each* ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the $m-1$ independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r} \sum_{k=1}^{N_k} \left(\frac{R_{rk} - R_r}{\delta R_{rk}} \right)^2 , \tag{3}$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values $\overline{P}_i$, we calculate an error matrix $\langle \delta\overline{P}_i \, \delta\overline{P}_j \rangle$. We tabulate the diagonal elements of $\delta\overline{P}_i = \langle \delta\overline{P}_i \, \delta\overline{P}_i \rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Full Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

Three comments on the example above:

(1) There was no connection assumed between measurements of the full width and the branching ratios. But often we also have information on partial widths Γ_i as well as the total width Γ. In this case we must introduce Γ as a parameter in the fit, along with the P_i, and we give correlation matrices for the widths in the Full Listings.

(2) We do *not* allow for correlations between input data. We *do* try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent.

(3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2. According to Eq. (3), the double sum for χ^2 is first summed over experiments $k = 1$ to N_k, leaving a single sum over ratios $\chi^2 = \sum \chi^2_r$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi^2_r / \langle \chi^2_r \rangle$. However, since $\langle \chi^2_r \rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_r^2 = \frac{1}{N_k} \sum_{k=1}^{N_k} \frac{(R_{rk} - \overline{R}_r)^2}{(\delta R_{rk})^2 - (\delta \overline{R}_r)^2} , \tag{4}$$

where $\delta\overline{R}_r$ is the fitted error for ratio r. With this definition the expected value of S_r^2 is one.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new

and often larger errors $\delta\overline{P}_i'$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta\overline{P}_i'/\delta\overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of $\overline{P}_i$ obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) $\overline{P}_i$ turns out to be less than three standard deviations ($\delta\overline{P}_i'$) from zero, a new smaller error $(\delta\overline{P}_i'')^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta\overline{P}_i'')^-$ and $\overline{P}_i$ to be 68.3% of the area between zero and $\overline{P}_i$. A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

4.3. ***Discussion***: The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Full Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like $\hbar$, *etc.* Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 0.2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting the uncertainty introduced by the new and inconsistent data. By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the *Review of Particle Properties* is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098, by the U.S. National Science Foundation under Agreement No. PHY-9320551, and by the Italian Istituto Nazionale di Fisica Nucleare (INFN). Partial funding to cover the cost of this *Review* is also provided by the European Laboratory for Particle Physics (CERN) and by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development.

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors. The Berkeley members of the Particle Data Group acknowledge the administrative and baking skills of Gail Harper and the graphics expertise of Charles Groom.

Revised by G.S. Wagman and B. Armstrong, June 1994

The Full Listings in this *Review of Particle Properties*, as well as other particle physics databases, are computer accessible. Some of the databases help find papers of interest, while others contain actual numerical data. Here we describe some databases maintained at LBL, SLAC, CERN, Durham, IHEP, KEK, and Yukawa, and how to start using them.

1. High-Energy Physics Databases

This section describes publicly accessible databases of interest to high-energy physicists. See Table 1 for availability, contacts, and user guides. For databases that are derived from other databases, see also the description of the originating database. See Section 2 for information on accessing these databases.

RPP contains the Full Listings from this *Review of Particle Properties*. Through user-friendly menus, users may query by paper, particle, mass range, quantum numbers, or detector, and can select specific properties or classes of properties like masses or decay parameters. All other relevant information (*e.g.*, footnotes and references) is included. Complete instructions are available online. The database is completely updated in the Summer of even-numbered years before publication of the *Review*, and is less thoroughly updated in the Summer of odd-numbered years.

The Particle Data Group provides, through the World-Wide Web (see Section 2.2), full-text PostScript of the *Review of Particle Properties*, excluding the Full Listings. For example, users may access the articles, tables, figures, and formulae.

Other High-Energy Physics Databases:

- ***BOOKS*** contains bibliographic summaries of more than 20,000 textbooks, conference proceedings, lecture-notes, monographs, and serials covering high-energy physics and related subjects.
- ***CONF (CERN)***, a subset of ***LIB***, contains forthcoming conferences of interest for high-energy physics and accelerator research and contains past conferences back to 1986.
- ***CONF (SLAC)*** contains almost 5,000 listings of conferences, schools, and meetings of interest to high-energy physicists. Information on forthcoming conferences is entered regularly, with detailed descriptions and links to further World-Wide Web information when available.
- ***CS***, regularly updated from the ***REACTIONS*** database, contains data from CERN-HERA, UCRL, and LBL cross-section compilations covering 1950 to the present.
- ***DIR***, the Directory of Research Institutes in High Energy Physics, contains addresses, telephone, fax, and telex numbers, and e-mail nodes, as well as brief information on research programs and accelerators.

  To obtain ***DIR*** in a Filemaker PRO format for Macintosh computers, contact the SIS Secretariat at CERN or Wolfgang Simon (`ISI@CERNVM.CERN.CH`).
- ***DOCUMENTS*** contains two groups of keys:

  (1) Bibliographic: ID, references, year of preprinting or publication, authors and affiliations, document title, experiment number, collaboration name, and related references.

  (2) Topical: beam particle, target particle, reactions, particles in the final states of reactions, momenta in initial states, types of data obtained, particles whose property has been measured, accelerator and/or detector, and initial state polarization.

  It covers 1895 to the present, with coverage since 1950 being more complete, and is updated monthly. The report "A Guide to Experimental Elementary Particle Physics Literature" [1] is produced from it.
- ***E-MAIL IDS***, derived from ***HEPNAMES***, contains e-mail addresses of many people working in high-energy physics.
- ***EXPERIMENTS*** contains summaries of approved experiments at major laboratories. It covers approximately 1975 to the present, with coverage since 1980 being more complete. It is searchable by experiment number, author, accelerator, detector, reaction, beam momentum, journal paper, and other items. The report "Current Experiments in Elementary Particle Physics" [2] is produced from it.
- ***HEP-PREPRINT*** is a collection of bulletin board archives reserved for high-energy physics preprints. It includes ***HEP-EX*** for experimental HEP preprints (since April 1994), ***HEP-LAT*** for lattice/computational preprints (since December 1991), ***HEP-PH*** for particle phenomenology preprints (since March 1992), and ***HEP-TH*** for string/conformal/field theory preprints (since August 1991). Other archives are described in the `HELP` facility of these archives.
- ***HEP (SPIRES-HEP)***, a joint project of the SLAC and DESY libraries, contains 270,000 bibliographic entries on particle physics papers (journal articles, preprints, reports, theses, *etc.*). It covers 1974 to the present and is updated daily. It is searchable by author, institution, title, topic, report number, citation, bulletin board number, and other bibliographic items. It is an indexing and access tool (via the World-Wide Web) to more than 12,000 full-text PostScript documents, including bulletin board articles processed jointly by the SLAC and DESY libraries and the CERN publication group.
- ***HEPNAMES*** contains 23,000 e-mail addresses of many people working in high-energy physics.
- ***INSTITUTIONS*** contains 3,000 addresses and, often, phone and fax numbers of high-energy physics-related institutions.
- ***LIB*** contains the CERN library's catalogue of books, reports, preprints, and other information.
- ***PP*** contains information on particle properties derived from the Summary Tables in this *Review of Particle Properties*.

(continued)

Table 1 (continuation)

[1] ***CONF (CERN)*** and ***CONF (SLAC)*** are similar in nature, but are not identical.

[2] Updated mainly from ***REACTIONS*** and maintained by the IHEP COMPAS Group.

[3] Maintained by the IHEP COMPAS Group with input from the LBL Particle Data Group, ITEP, and JINR. Bibliographic data is extracted from ***SPIRES-HEP*** and ***LIB***.

[4] Derived from ***HEPNAMES***.

[5] Maintained by SLAC, transferred to other institutions. (Ref. 2).

[6] Maintained by SLAC in collaboration with the DESY HEP Index Group, transferred to other institutions nightly.

[7] Maintained by SLAC in collaboration with the LBL Particle Data Group.

[8] Derived from the Summary Tables in this *Review of Particle Properties*; maintained by the IHEP COMPAS Group.

[9] Maintained by the HEP Database Group at Durham; data exchanged twice yearly with IHEP.

[10] Maintained by the IHEP COMPAS Group with input from ITEP; data exchanged twice yearly with Durham.

[11] Derived from the Full Listings in this *Review of Particle Properties*.

[12] A subset of ***SPIRES-HEP***.

[13] Maintained by the IHEP COMPAS Group with input from ***RPP*** and ***EXPERIMENTS***.

- ***PREP***, a subset of ***LIB***, contains entries for preprints, reports, conference papers, theses, *etc.* It covers all preprints and reports received in the CERN Library since 1980. It also has publication details for all papers published with CERN as an affiliation and for many conference papers published in proceedings since about 1987.
- ***REACTION DATA*** is a compilation of numerical experimental particle physics reaction data, including data from 2-body (and quasi-2-body) scattering, e^+e^- annihilation, and inclusive hadron, photon, and lepton physics such as total and differential cross sections, fragmentation functions, structure functions, and polarization measurements.
- ***REACTIONS***, in conjunction with ***REACTION DATA***, contains numerical data on reactions: differential and total cross sections, structure functions, polarization measurements, and other quantities. It covers 1952 to the present and is updated approximately quarterly.
- ***SLACPPF/CITATIONS***, a subset of the ***SPIRES-HEP*** literature-searching guide, contains references to papers and preprints since 1980, being comprised of the SLAC PPF (preprint) records with PPA (published references to PPF) updates compiled by the SLAC library. Many journal publications compiled by the DESY library are also included.
- ***VOCABULARY*** controls usage of particle names, accelerator names, detector names, and data descriptors in all PPDS databases.

2. Accessing the High-Energy Physics Databases

2.1. *Menu-Driven RPP Database at LBL*

To access the ***RPP*** database on INTERNET: `TELNET MUSE.LBL.GOV` (`131.243.48.11`) or on DECNET: `SET HOST MUSE` (42062). Then login to the captive account `PDG_PUBLIC` (a password is not required).

2.2. *Databases on the INTERNET/World-Wide Web*

Many databases, including several of the high-energy physics databases discussed above, are accessible via the World-Wide Web (W3 or WWW) (see Table 1), which is an INTERNET-based wide-area hypermedia information retrieval system. There are several browsers available (WWW line-mode browser, NCSA's Mosaic browser for X Windows, SLAC's MidasWWW browser for X Windows, Cello browser for MSDOS, *etc.*.) that may already be installed at your institution; if not, try `TELNET INFO.CERN.CH`, which will connect you to WWW and will explain how to acquire the browsers.

Much of this *Review of Particle Properties* can be accessed through the World-Wide Web link

`http://www-pdg.lbl.gov/`

2.3. *Library Databases on ALICE at CERN*

The CERN Library ALICE databases are accessible through the World-Wide Web link

`http://www.cern.ch/`

This link and the subsequent "Preprints" link also provide access to full-text preprints received since 1994 from bulletin board archives and from scanned papers.

To access ALICE on INTERNET: `TELNET ALICE.CERN.CH` (`128.141.201.44`) or on DECNET: `SET HOST VXLIB` (22748). Then login to account `ALICE` (a password is not required) and select the terminal type according to the menu. ALICE is a full-screen system using the DEC international character set, which can be displayed on suitable terminals. Simple searching can be done by using a menu system or by using the full power of the ISO Common Command Language; HELP displays are provided to guide searching. With the MAIL command, the results of searches can be sent to any e-mail address for printing.

People without login access to CERN can use QALICE.

Typical messages from OpenVMS to QALICE:

```
msg VXLIB QALICE base prep;f black hole?;
msg VXLIB QALICE base and 1991-->1992/yr;show
msg VXLIB QALICE base dir;f org=cern;show full
```

Alternately, send a blank e-mail message to

`QALICE@VXLIB.CERN.CH`

and put the query in the subject field. For further information, send the subject `HELP` to QALICE.

Regular weekly or monthly searches of the CERN databases can be arranged according to a personal search 'profile', with the results sent automatically by e-mail. For details on this Selective Dissemination of Information (SDI) service on QALICE, contact David Dallman, Scientific Information Service (SIS), CERN, CH-1211 Geneva 23, Switzerland (`DALLMAN@CERNVM.CERN.CH`).

2.4. *Databases on SPIRES at SLAC*

SLAC encourages the high-energy physics community to access its databases through the World-Wide Web link

`http://www-slac.slac.stanford.edu/find/spires.html`

leading to ***SPIRES-HEP***, ***BOOKS***, ***CONF***, ***HEPNAMES***, ***INSTITUTIONS***, ***EXPERIMENTS***, and other SLAC databases.

People without login access or World-Wide Web access to SLAC can use QSPIRES. QSPIRES, as described in the 1992 edition of the *Review of Particle Properties*, is a remote server which enables e-mail access to SPIRES databases. Effective March 1994, registration or authorization is no longer needed to access QSPIRES. For further information on QSPIRES, contact `QSPI@SLAC.STANFORD.EDU`.

2.5. *Online Access to HEP at DESY*

DESY offers accounts for remote login from Europe restricted to ***SPIRES-HEP***. Contact Hartmut Preissner (LOOHTP@DSYIBM.DESY.DE).

2.6. *Databases on SPIRES at Yukawa Institute*

The Yukawa Institute provides Gopher access (GOPHER.YUKAWA.KYOTO-U.AC.JP) and QSPIRES access (JPNYITP.YUKAWA.KYOTO-U.AC.JP) from the Far East to SPIRES databases. Contact Ken-Ichi Aoki (AOKI@HEP.S.KANAZAWA-U.AC.JP).

2.7. *High-Energy Physics Bulletin Board Preprint Archives*

E-mail listings of high-energy physics preprint titles and abstracts submitted to the archives can be received daily by sending a blank e-mail message to the appropriate archive (HEP-EX@XXX.LANL.GOV, HEP-LAT@FTP.SCRI.FSU.EDU, HEP-PH@XXX.LANL.GOV, or HEP-TH@XXX.LANL.GOV) with the subject:

SUBSCRIBE *your_name*

To receive detailed instructions on submitting and recovering papers, send a blank e-mail message with the subject:

HELP

The listings and papers can also be accessed through the World-Wide Web link

http://xxx.lanl.gov/

2.8. *IHEP-LBL Particle Physics Data System (PPDS) at LBL*

The databases maintained by the IHEP Protvino COMPAS Group under the Berkeley Database Management System (BDMS) with input from the world-wide Particle Data Group collaboration can be accessed interactively on INTERNET: TELNET MUSE.LBL.GOV (131.243.48.11) or on DECNET: SET HOST MUSE (42062). Then login to the captive account PPDS_PUBLIC (a password is not required).

Otherwise, remote interactive access can be achieved from other OpenVMS computers with DECNET access to MUSE. The remote software (20,000 blocks) can be obtained from LUGOVSKY@MX.IHEP.SU or PDG@LBL.GOV and can then be initialized by the system manager or by having each user type:

@*disk*:[*directory*.COMPAS.BDMS.COM]BDMSINI

In the following description, words in **Typewriter Font** must be typed as given. Only the letters in UPPER CASE are necessary and these must be entered in upper case. *Italic words* are variables for which the user substitutes an appropriate value, again in upper case.

- To enter the system and obtain general information, type:

  PPDS

  or, to open a particular database, type:

  PPDS *database_name*

  (*e.g.*, PPDS DOCuments)

- For a short explanation of the database, type:

  HELpbase

- For a list of BDMS commands, type:

  ?

- For an explanation of a particular BDMS command, type:

  ?*command_word*

  (*e.g.*, ?FInd, ?HELpbase, ??)

- To see the record structure and names of keys for searching, type:

  FDT

- To browse the index of a key, type:

  INDex,*key_name*

  (*e.g.*, INDex,AC)

- To search an index, type:

  FInd *key_name=key_value*;**

  Note the use of '**' to terminate each search statement and the use of ';' to separate data elements.

  The following examples typify the FIND search command.

  FInd AC=BNL;**

  FInd AC=BNL; OR AC=BONN;**

  Each successful search produces a list of all previous searches and labels them with a 'set number.' A previous search result can then be combined with a current search by use of set numbers:

  FInd (1) and RE=PI+ P --> PI+ P;**

  FInd (1) and (2) **

  Note that ';' is not used in searches that only use 'sets'.

  Enter DIR to get a list of these set numbers and search commands.

- To do a truncated search, use a slash after the key value:

  FInd DE=HBC/;**

  This finds all detectors that begin with HBC.

- To do a string search, use /C after the key name:

  FInd DE/C=BC;**

  This finds all detectors that have BC anywhere in the name.

- The following examples are WRONG:

  find ac=bnl;** (Error: uses lowercase)

  FInd AC BNL;** (Error: no '=')

  FInd AC=BNL ** (Error: no ';')

  FInd AC=BNL OR BONN;** (Error: no ';' & no 'AC=')

- To see the results of a search with key names, type:

  LISt

- Or to restrict data elements shown, append the desired key names. For example:

  LISt,AC,RE,SC.

  The leading comma and terminal period are required.

- Or for an attractive listing, type:

  DOcument then

  LOokfile

- Remote users may save the result of a search in a file by typing one of the following:

```
DOcument
DUmp
PRInt
```

The results are stored in the files `DOC.DOC`, `DOC.DUM`, or `DOC.PRN`. The first file contains a user-friendly listing, the second contains a highly compressed dump of each record (with data element and value), and the third contains a line-by-line decompressed version of the second file. Another file automatically created, `DOC.AUD`, contains a history of your commands.

2.9. *Durham-RAL Databases on BDMS at Durham and CERN*

Databases running under the Berkeley Database Management System (BDMS) that are menu driven with on-line help information are available on the CERN IBM/VM system and on the Durham OpenVMS system. To access the VM system on INTERNET: `TELNET CERNVM.CERN.CH (128.141.2.4)` and enter `GIME UDISK` followed by `HEPDATA`. To access the Durham OpenVMS system on INTERNET: `TELNET DURPDG.DUR.AC.UK (129.234.8.100)` or on DECNET: `SET HOST DURPDG (19788)`. A guest account `PDG`, password `HEPDATA`, is available on this machine.

Retrieve data by using simple keyword-based searches; resulting data records can be listed on the terminal or transferred to the user's own host machine.

(Approximate closing date for data: January 1, 1994)

GAUGE AND HIGGS BOSONS

γ

$I(J^{PC}) = 0,1(1^{--})$

Mass $m < 3 \times 10^{-27}$ eV
Charge $q < 2 \times 10^{-32}$ e
Mean life τ = Stable

g or gluon

$I(J^{P}) = 0(1^{-})$

Mass $m = 0$ [a]
SU(3) color octet

W

$J = 1$

Charge = ± 1 e
Mass $m = 80.22 \pm 0.26$ GeV
$m_Z - m_W = 10.96 \pm 0.26$ GeV
$m_{W^+} - m_{W^-} = -0.2 \pm 0.6$ GeV
Full width $\Gamma = 2.08 \pm 0.07$ GeV

W^- modes are charge conjugates of the modes below.

W^+ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$e^+\nu$		(10.8±0.4) %		40100
$\mu^+\nu$		(10.6±0.7) %		40100
$\tau^+\nu$		(10.8±1.0) %		40100
$\ell^+\nu$	[b]	(10.7±0.5) %		40100
hadrons		(67.8±1.5) %		–
$\pi^+\gamma$		< 5 × 10^{-4}	95%	40110

Z

$J = 1$

Charge = 0
Mass $m = 91.187 \pm 0.007$ GeV [c]
Full width $\Gamma = 2.490 \pm 0.007$ GeV
$\Gamma(\ell^+\ell^-) = 83.84 \pm 0.27$ MeV [b]
Γ(invisible) $= 498.2 \pm 4.2$ MeV [d]
Γ(hadrons) $= 1740.7 \pm 5.9$ MeV
$\Gamma(\mu^+\mu^-)/\Gamma(e^+e^-) = 1.000 \pm 0.005$
$\Gamma(\tau^+\tau^-)/\Gamma(e^+e^-) = 0.998 \pm 0.005$ [e]
$g_V^\ell = -0.0377 \pm 0.0016$
$g_A^\ell = -0.5008 \pm 0.0008$

Asymmetry parameters

$A_e = 0.161 \pm 0.012$ [f] (S = 1.7)
$A_\tau = 0.141 \pm 0.021$ [f] (S = 1.2)

Charge asymmetry at Z pole

$A_{FB}^{(0,\ell)} = (1.59 \pm 0.18) \times 10^{-2}$
$A_{FB}^{(0,c)} = (5.8 \pm 2.2) \times 10^{-2}$
$A_{FB}^{(0,b)} = (10.7 \pm 1.3) \times 10^{-2}$

Gauge & Higgs Boson Summary Table

Searches for Higgs Bosons — H^0 and $H^\pm$

H^0 Mass $m >$ 58.4 GeV, CL = 95%

H_1^0 in Supersymmetric Models ($m_{H_1^0} < m_{H_2^0}$) [j]

Mass $m >$ 44 GeV, CL = 95% for $\tan\beta > 1$

A^0 Pseudoscalar Higgs Boson in Supersymmetric Models [j]

Mass $m >$ 22 GeV, CL = 95% for $50 > \tan\beta > 1$

$H^\pm$ Mass $m >$ 41.7 GeV, CL = 95%

See the Full Listings for a Note giving details of Higgs Bosons.

Searches for Heavy Bosons Other Than Higgs Bosons

Additional W Bosons

W_R — right-handed W

Mass $m >$ 406 GeV, CL = 90%
(assuming light right-handed neutrino)

W' with standard couplings decaying to $e\nu$, $\mu\nu$

Mass $m >$ 520 GeV, CL = 95%

Additional Z Bosons

Z'_{SM} with standard couplings

Mass $m >$ 412 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m >$ 779 GeV, CL = 95% (electroweak fit)

Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$
(with $g_L = g_R$)

Mass $m >$ 310 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m >$ 389 GeV, CL = 95% (electroweak fit)

Z_χ of $SO(10) \rightarrow SU(5) \times U(1)_\chi$
(coupling constant derived from G.U.T.)

Mass $m >$ 340 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m >$ 321 GeV, CL = 95% (electroweak fit)

Z_ψ of $E_6 \rightarrow SO(10) \times U(1)_\psi$
(coupling constant derived from G.U.T.)

Mass $m >$ 320 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m >$ 160 GeV, CL = 95% (electroweak fit)

Z_η of $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$
(coupling constant derived from G.U.T.;
charges are $Q_\eta = \sqrt{3/8}Q_\chi - \sqrt{5/8}Q_\psi$)

Mass $m >$ 340 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m >$ 182 GeV, CL = 95% (electroweak fit)

Scalar Leptoquarks

Mass $m >$ 120 GeV, CL = 95% (1st generation, pair prod.)

Mass $m >$ 181 GeV, CL = 95% (1st gener., single prod.)

Mass $m >$ 44.5 GeV, CL = 95% (2nd gener., pair prod.)

Mass $m >$ 73 GeV, CL = 95% (2nd gener., single prod.)

Mass $m >$ 45 GeV, CL = 95% (3rd gener., pair prod.)

(last four limits are for charge $-1/3$, weak isoscalar)

Searches for Axions (A^0) and Other Very Light Bosons

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Full Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Full Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] Theoretical value. A mass as large as a few MeV may not be precluded.

[b] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[c] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy plane) in the Z-boson propagator.

[d] This partial width takes into account Z decays into $\nu\bar{\nu}$ and any other possible undetected modes.

[e] This ratio has not been corrected for the τ mass.

[f] Here $A \equiv 2g_V g_A/(g_V^2+g_A^2)$.

[g] The value is for the sum of the charge states indicated.

[h] See the Z Full Listings for the γ energy range used in this measurement.

[i] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

[j] The limits assume no invisible decays.

LEPTONS

Neutrinos

See the Full Listings for a Note giving details of neutrinos, masses, mixing, and the status of experimental searches.

ν_e

$J = \frac{1}{2}$

Mass m: The formal upper limit, as obtained from the m^2 average (see the Full Listings), is 5.1 eV at the 95% CL. Caution is urged in interpreting this result, since the m^2 average is positive with only a 3.5% probability. If the weighted average m^2 were forced to zero, the limit would increase to 7.0 eV.
Mean life/mass, $\tau/m_{\nu_e} > 300$ s/eV, CL = 90%
Magnetic moment $\mu < 1.08 \times 10^{-9}\ \mu_B$, CL = 90%

ν_μ

$J = \frac{1}{2}$

Mass $m < 0.27$ MeV, CL = 90%
Mean life/mass, $\tau/m_{\nu_\mu} > 15.4$ s/eV, CL = 90%
Magnetic moment $\mu < 7.4 \times 10^{-10}\ \mu_B$, CL = 90%

ν_τ

$J = \frac{1}{2}$

Mass $m < 31$ MeV, CL = 95%
Magnetic moment $\mu < 5.4 \times 10^{-7}\ \mu_B$, CL = 90%

e

$J = \frac{1}{2}$

Mass $m = 0.51099906 \pm 0.00000015$ MeV [a]
$= (5.48579903 \pm 0.00000013) \times 10^{-4}$ u
$(m_{e^+} - m_{e^-})/m < 4 \times 10^{-8}$, CL = 90%
$|q_{e^+} + q_{e^-}|/e < 4 \times 10^{-8}$
Magnetic moment $\mu = 1.001159652193 \pm 0.000000000010\ \mu_B$
$(g_{e^+} - g_{e^-})\ /\ g_{\rm average} = (-0.5 \pm 2.1) \times 10^{-12}$
Electric dipole moment $d = (-0.3 \pm 0.8) \times 10^{-26}\ e$cm
Mean life $\tau > 2.7 \times 10^{23}$ yr, CL = 68% [b]

μ

$J = \frac{1}{2}$

Mass $m = 105.658389 \pm 0.000034$ MeV [a]
$= 0.113428913 \pm 0.000000017$ u
Mean life $\tau = (2.19703 \pm 0.00004) \times 10^{-6}$ s
$\tau_{\mu^+}/\tau_{\mu^-} = 1.00002 \pm 0.00008$
$c\tau = 658.654$ m
Magnetic moment $\mu = 1.001165923 \pm 0.000000008\ e\hbar/2m_\mu$
$(g_{\mu^+} - g_{\mu^-})\ /\ g_{\rm average} = (-2.6 \pm 1.6) \times 10^{-8}$
Electric dipole moment $d = (3.7 \pm 3.4) \times 10^{-19}\ e$cm

Decay parameters [c]

$\rho = 0.7518 \pm 0.0026$
$\eta = -0.007 \pm 0.013$
$\delta = 0.749 \pm 0.004$
$\xi P_\mu = 1.003 \pm 0.008$ [d]
$\xi P_\mu \delta/\rho > 0.99682$, CL = 90% [d]
$\xi' = 1.00 \pm 0.04$
$\xi'' = 0.7 \pm 0.4$
$\alpha/A = (0 \pm 4) \times 10^{-3}$
$\alpha'/A = (0 \pm 4) \times 10^{-3}$
$\beta/A = (4 \pm 6) \times 10^{-3}$
$\beta'/A = (2 \pm 6) \times 10^{-3}$
$\overline{\eta} = 0.02 \pm 0.08$

μ^+ modes are charge conjugates of the modes below.

μ^- DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$e^-\overline{\nu}_e\nu_\mu$		$\approx 100\%$		53
$e^-\overline{\nu}_e\nu_\mu\gamma$	[e]	(1.4 ± 0.4) %		53
$e^-\overline{\nu}_e\nu_\mu e^+e^-$	[f]	$(3.4 \pm 0.4) \times 10^{-5}$		53
Lepton Family number (*LF*) violating modes				
$e^-\nu_e\overline{\nu}_\mu$	*LF* [g]	< 1.2 %	90%	53
$e^-\gamma$	*LF*	$< 4.9 \times 10^{-11}$	90%	53
$e^-e^+e^-$	*LF*	$< 1.0 \times 10^{-12}$	90%	53
$e^-2\gamma$	*LF*	$< 7.2 \times 10^{-11}$	90%	53

τ

$J = \frac{1}{2}$

Mass $m = 1777.1^{+0.4}_{-0.5}$ MeV
Mean life $\tau = (295.6 \pm 3.1) \times 10^{-15}$ s
$c\tau = 88.6\ \mu$m
Electric dipole moment $d < 5 \times 10^{-17}\ e$cm, CL = 95%
Weak dipole moment $< 3.7 \times 10^{-17}\ e$cm, CL = 95%

Decay parameters

See the τ Full Listings for a note concerning τ-decay parameters.
$\rho^\tau(e \text{ or } \mu) = 0.74 \pm 0.04$
$\rho^\tau(e) = 0.72 \pm 0.04$
$\rho^\tau(\mu) = 0.76 \pm 0.05$
$\xi^\tau(e \text{ or } \mu) = 0.90 \pm 0.18$
W-τ couplings $2g_Ag_V/(g_A^2+g_V^2) = 1.25^{+0.27}_{-0.24}$

τ^+ modes are charge conjugates of the modes below. "$h^\pm$" stands for $\pi^\pm$ or $K^\pm$. "ℓ" stands for e or μ. "Neutral" means neutral hadron whose decay products include γ's and/or π^0's.

τ^- DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
Modes with one charged particle			
particle$^- \geq 0$ neutrals ν_τ ("1-prong")	(85.49±0.24) %	S=1.5	–

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes
(In the modes below, ℓ means a sum over e and μ modes)

L means lepton number violation (*e.g.* $\tau^- \to e^+\pi^-\pi^-$). Following common usage, LF means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \to e^-\pi^+\pi^-$).

$e^-\gamma$	LF		< 1.2	$\times 10^{-4}$	CL=90%	889
$\mu^-\gamma$	LF		< 4.2	$\times 10^{-6}$	CL=90%	885
$e^-\pi^0$	LF		< 1.4	$\times 10^{-4}$	CL=90%	883
$\mu^-\pi^0$	LF		< 4.4	$\times 10^{-5}$	CL=90%	880
e^-K^0	LF		< 1.3	$\times 10^{-3}$	CL=90%	819
μ^-K^0	LF		< 1.0	$\times 10^{-3}$	CL=90%	815
$e^-\eta$	LF		< 6.3	$\times 10^{-5}$	CL=90%	804
$\mu^-\eta$	LF		< 7.3	$\times 10^{-5}$	CL=90%	800
$e^-\rho^0$	LF		< 1.9	$\times 10^{-5}$	CL=90%	723
$\mu^-\rho^0$	LF		< 2.9	$\times 10^{-5}$	CL=90%	718
$e^-K^*(892)^0$	LF		< 3.8	$\times 10^{-5}$	CL=90%	665
$\mu^-K^*(892)^0$	LF		< 4.5	$\times 10^{-5}$	CL=90%	660

Number of Light Neutrino Types

(including ν_e, ν_μ, and ν_τ)

Number $N = 2.983 \pm 0.025$ (Standard Model fits to Z data)

Number $N = 2.97 \pm 0.17$ (Direct measurement of invisible Z width)

Heavy Lepton Searches

$L^\pm$ – charged lepton

Mass $m >$ 44.3 GeV, CL = 95% $m_\nu \approx 0$

$L^\pm$ – stable charged heavy lepton

Mass $m >$ 42.8 GeV, CL = 95%

L^0 – stable neutral heavy lepton

Mass $m >$ 45.0 GeV, CL = 95% (Dirac)

Mass $m >$ 39.5 GeV, CL = 95% (Majorana)

Neutral heavy lepton

Mass $m >$ 19.6 GeV, CL = 95% (all $|U_{\ell J}|^2$) (Dirac)

Mass $m >$ 45.7 GeV or $m < 25$, CL = 95% ($|U_{\ell J}|^2 > 10^{-13}$ (Dirac)

Searches for Massive Neutrinos and Lepton Mixing

For excited leptons, see Compositeness Limits below.

See the Full Listings for a Note giving details of neutrinos, masses, mixing, and the status of experimental searches.

No direct, uncontested evidence for massive neutrinos or lepton mixing has been obtained. Sample limits are:

ν oscillation: $\overline{\nu}_e \not\to \overline{\nu}_e$

$\Delta(m^2) < 0.0083$ eV^2, CL = 90% (if $\sin^2 2\theta = 1$)

$\sin^2 2\theta < 0.14$, CL = 68% (if $\Delta(m^2)$ is large)

ν oscillation: $\nu_\mu \to \nu_e$ (θ = mixing angle)

$\Delta(m^2) < 0.09$ eV^2, CL = 90% (if $\sin^2 2\theta = 1$)

$\sin^2 2\theta < 2.5 \times 10^{-3}$, CL = 90% (if $\Delta(m^2)$ is large)

QUARKS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\text{MS}}$ at a scale $\mu \approx 1$ GeV. The c- and b-quark masses are estimated from charmonium, bottomonium, D, and B masses. They are the "running" masses in the $\overline{\text{MS}}$ scheme. These can be different from the heavy quark masses obtained in potential models.

u

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 2$ to 8 MeV [j] Charge $= \frac{2}{3}\,e$ $I_z = +\frac{1}{2}$
$m_u/m_d = 0.25$ to 0.70

d

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 5$ to 15 MeV [j] Charge $= -\frac{1}{3}\,e$ $I_z = -\frac{1}{2}$
$m_s/m_d = 17$ to 25

s

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 100$ to 300 MeV [j] Charge $= -\frac{1}{3}\,e$ Strangeness $= -1$
$(m_s - (m_u + m_d)/2)/(m_d - m_u) = 34$ to 51

c

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 1.0$ to 1.6 GeV Charge $= \frac{2}{3}\,e$ Charm $= +1$

b

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 4.1$ to 4.5 GeV Charge $= -\frac{1}{3}\,e$ Bottom $= -1$

Searches for t Quark

$I(J^P) = 0(\frac{1}{2}^+)$

Charge $= \frac{2}{3}\,e$ Top $= +1$

Mass $m >$ 62 GeV, CL = 95% (all decays)
Mass $m >$ 131 GeV, CL = 95% (assumes $t \to W\,b$ decay)
Mass $m = 174 \pm 10^{+13}_{-12}$ GeV (top candidate events)
Mass $m = 169^{+16+17}_{-18-20}$ GeV (Standard Model electroweak fit)

The first result is from a CDF $\Gamma(W)$ measurement; the second is from a DØ direct search; the third is from a CDF observation of top candidate events. CDF observes a 2.8σ effect which is not sufficient to firmly establish the existence of top but which, if interpreted as top, yields the third result. The fourth result is from a Standard Model electroweak fit to Z, W, and νN data not including direct m_t measurements. The central value assumes $m_H = 300$ GeV while the second upper (lower) error corresponds to $m_H = 1000$ (60) GeV.

Searches for b′ (4th Generation) Quark

Mass $m >$ 85 GeV, CL = 95% ($p\overline{p}$, charged current decays)
Mass $m >$ 46.0 GeV, CL = 95% (e^+e^-, all decays)

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{X^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Full Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] The masses of the e and μ are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.49432(28) MeV, is less well known than are the masses in u.

[b] This is the best "electron disappearance" limit. The best limit for the mode $e^- \to \nu\gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).

[c] See the "Note on Muon Decay Parameters" in the μ Full Listings for definitions and details.

[d] P_μ is the longitudinal polarization of the muon from pion decay. In standard $V-A$ theory, $P_\mu = 1$ and $\rho = \delta = 3/4$.

[e] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\nu_\mu$ and $e^-\overline{\nu}_e\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[f] See the μ Full Listings for the energy limits used in this measurement.

[g] A test of additive vs. multiplicative lepton family number conservation.

[h] ℓ means a sum over e and μ modes.

[i] The value is for the sum of the charge states indicated.

[j] The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of u and d masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

Meson Summary Table

LIGHT UNFLAVORED MESONS ($S = C = B = 0$)

For $I = 1$ (π, b, ρ, a): $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$;
for $I = 0$ (η, η', h, h', ω, ϕ, f, f'): $c_1(u\overline{u}+d\overline{d})+c_2(s\overline{s})$

$\pi^\pm$

$I^G(J^P) = 1^-(0^-)$

Mass $m = 139.56995 \pm 0.00035$ MeV [a]
Mean life $\tau = (2.6030 \pm 0.0024) \times 10^{-8}$ s
$c\tau = 7.804$ m

$\pi^\pm \to \ell^\pm \nu\gamma$ form factors [b]

$F_V = 0.017 \pm 0.008$
$F_A = 0.0116 \pm 0.0016$ (S = 1.3)
$R = 0.059^{+0.009}_{-0.008}$

π^- modes are charge conjugates of the modes below.

π^+ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)

$D_2^*(2460)^\pm \rightarrow D^0\pi^+$	seen	505

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$D_s^+ = c\overline{s}$, $D_s^- = \overline{c}s$, similarly for D_s^*'s

$D_s^\pm$ was $F^\pm$

$I(J^P) = 0(0^-)$

Mass $m = 1968.5 \pm 0.7$ MeV (S = 1.2)
$m_{D_s^\pm} - m_{D^\pm} = 99.1 \pm 0.6$ MeV (S = 1.1)
Mean life $\tau = (0.467 \pm 0.017) \times 10^{-12}$ s
$c\tau = 140$ μm

Branching fractions for modes below with a resonance in the final state include all the decay modes of the resonance. D_s^- modes are charge conjugates of the modes below.

Nearly all other modes are measured relative to the $\phi\pi^+$ mode. However, none of the determinations of the $\phi\pi^+$ branching fraction are direct measurements: all rely on calculated relations between D^+ and D_s^+ decay widths, on estimates of D_s^+ cross sections, or on other model-dependent assumptions. Thus a better determination of the $\phi\pi^+$ branching fraction could cause the other branching fractions to slide up or down, all together.

Full width $\Gamma < 2.3$ MeV, CL = 90%

$D_{s1}(2536)^-$ modes are charge conjugates of the modes below.

$D_{s1}(2536)^+$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$D^*(2010)^+K^0$	seen	150
$D^*(2007)^0K^+$	seen	169
D^+K^0	not seen	382
D^0K^+	not seen	392
$D_s^{*+}\gamma$	possibly seen	389

BOTTOM MESONS ($B = \pm 1$)

$B^+ = u\bar{b}$, $B^0 = d\bar{b}$, $\bar{B}^0 = \bar{d}b$, $B^- = \bar{u}b$, similarly for B^*'s

$B^{\pm}$

$I(J^P) = \frac{1}{2}(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions. Measurements which do not identify the charge state of B also appear here.

Mass $m_{B^{\pm}} = 5278.7 \pm 2.0$ MeV
Mean life $\tau = (1.54 \pm 0.11) \times 10^{-12}$ s
Mean life τ (avg over B hadrons) $= (1.537 \pm 0.021) \times 10^{-12}$ s [a]
$c\tau = 388\ \mu$m

B^- modes are charge conjugates of the modes below.

Only data from $\Upsilon(4S)$ decays are used for branching fractions, with rare exceptions. The branching fractions listed below assume a 50:50 $B^0\bar{B}^0$:B^+B^- production ratio at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would effect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B^+ DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level		p (MeV/c)

B DECAY MODES

$\overline{B}$ modes are charge conjugates of the modes below.

For the following modes, the charge of B was not determined. The measurements are for an admixture of B mesons at the $\Upsilon(4S)$ unless otherwise indicated by a footnote and a "$\overline{b}$" instead of "B" in the initial state.

Semileptonic and leptonic modes

$B \to e^+ \nu_e$ anything	[c]	(10.4 ± 0.4) %		S=1.3	–
$B \to \overline{D}^*(2010) e^+ \nu_e$		(7.0 ± 2.3) %			–
$B \to \overline{p} e^+ \nu_e$ anything		< 1.6	$\times 10^{-3}$	CL=90%	–
$B \to \mu^+ \nu_\mu$ anything	[c]	(10.3 ± 0.5) %			–
$B \to \ell^+ \nu_\ell$ anything	[b,c]	(10.43± 0.24) %			–
$B \to D^- \ell^+ \nu_\ell$ anything	[b]	(2.7 ± 0.8) %			–
$B \to \overline{D}^0 \ell^+ \nu_\ell$ anything	[b]	(7.0 ± 1.4) %			–
$B \to D^{**} \ell^+ \nu_\ell$	[b,d]	(2.7 ± 0.7) %			–
$B \to D_s^- \ell^+ \nu_\ell$ anything	[b]	< 9	$\times 10^{-3}$	CL=90%	–
$B \to D_s^- \ell^+ \nu_\ell K^+$ anything	[b]	< 6	$\times 10^{-3}$	CL=90%	–
$B \to D_s^- \ell^+ \nu_\ell K^0$ anything	[b]	< 9	$\times 10^{-3}$	CL=90%	–
$B \to K^+ \ell^+ \nu_\ell$ anything	[b]	(5.6 ± 1.0) %			–
$B \to K^- \ell^+ \nu_\ell$ anything	[b]	(1.0 ± 0.6) %			–
$B \to K^0 / \overline{K}^0 \ell^+ \nu_\ell$ anything	[b]	(4.1 ± 0.8) %			–
$\overline{b} \to \tau^+ \nu_\tau$ anything	[e]	(4.1 ± 1.0) %			–

D, D^*, or D_s modes

$B \to D^-$ anything		(26 ± 4) %			–
$B \to \overline{D}^0$ anything		(54 ± 6) %			–
$B \to D^*(2010)^-$ anything		(23 ± 4) %		S=1.4	–
$B \to D_s^\pm$ anything	[f]	(8.9 ± 1.1) %			–
$B \to D_s D$, $D_s^* D$, $D_s D^*$, or $D_s^* D^*$	[f]	(5.0 ± 0.9) %			–
$B \to D^*(2010)\gamma$		< 1.1	$\times 10^{-3}$	CL=90%	–
$B \to D_s^+ \pi^-$, $D_s^{*+} \pi^-$, $D_s^+ \rho^-$, $D_s^{*+} \rho^-$, $D_s^+ \pi^0$, $D_s^{*+} \pi^0$, $D_s^+ \eta$, $D_s^{*+} \eta$, $D_s^+ \rho^0$, $D_s^{*+} \rho^0$, $D_s^+ \omega$, $D_s^{*+} \omega$		< 5	$\times 10^{-4}$	CL=90%	–

Charmonium modes

$B \to J/\psi(1S)$ anything	(1.30± 0.17) %			–
$B \to \psi(2S)$ anything	(4.6 ± 2.0)	$\times 10^{-3}$		–
$B \to \chi_{c1}(1P)$ anything	(1.1 ± 0.4) %			–

K or K^* modes

$B \to K^\pm$ anything	[f]	(85 ±11) %			–
$B \to K^0 / \overline{K}^0$ anything		(63 ± 8) %			–
$b \to s\gamma$	[g]	< 1.2	$\times 10^{-3}$	CL=90%	–
$B \to K^*(892)\gamma$		< 2.4	$\times 10^{-4}$	CL=90%	–
$B \to K_1(1400)\gamma$		< 4.1	$\times 10^{-4}$	CL=90%	–
$B \to K_2^*(1430)\gamma$		< 8.3	$\times 10^{-4}$	CL=90%	–
$B \to K_2(1770)\gamma$		< 1.2	$\times 10^{-3}$	CL=90%	–
$B \to K_3^*(1780)\gamma$		< 3.0	$\times 10^{-3}$	CL=90%	–
$B \to K_4^*(2045)\gamma$		< 1.0	$\times 10^{-3}$	CL=90%	–

Light unflavored meson modes

$B \to \phi$ anything		(2.3 ± 0.8) %			–

Baryon modes

$B \to$ charmed-baryon anything	(6.4 ± 1.1) %		–
$B \to \overline{\Sigma}_c^{--}$ anything	(4.8 ± 2.5) × 10^{-3}		–
$B \to \overline{\Sigma}_c^{-}$ anything	< 1.1 %	CL=90%	–
$B \to \overline{\Sigma}_c^{0}$ anything	(5.3 ± 2.5) × 10^{-3}		–
$B \to \overline{\Sigma}_c^{0} N (N = p$ or $n)$	< 1.7 × 10^{-3}	CL=90%	–
$B \to p$anything + $\overline{p}$anything	(8.0 ± 0.5) %		–
$B \to p$(direct) anything + $\overline{p}$(direct) anything	(5.6 ± 0.7) %		–
$B \to \Lambda$anything + $\overline{\Lambda}$anything	(4.0 ± 0.5) %		–
$B \to \Xi^-$anything + $\overline{\Xi}^+$anything	(2.7 ± 0.6) × 10^{-3}		–
$B \to$ baryons anything	(6.8 ± 0.6) %		–
$B \to p\overline{p}$anything	(2.47± 0.23) %		–
$B \to \Lambda\overline{p}$anything + $\overline{\Lambda}p$anything	(2.5 ± 0.4) %		–
$B \to \Lambda\overline{\Lambda}$anything	< 5 × 10^{-3}	CL=90%	–

$\Delta B = 1$ weak neutral current ($B1$) modes

$\overline{b} \to e^+e^-$anything	$B1$	[g] < 2.4 × 10^{-3}			–
$\overline{b} \to \mu^+\mu^-$anything	$B1$	[g] < 5.0 × 10^{-5}	CL=90%		–

B^0

$I(J^P) = \frac{1}{2}(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^0} = 5279.0 \pm 2.0$ MeV

$m_{B^0} - m_{B^\pm} = 0.34 \pm 0.29$ MeV (S = 1.1)

Mean life $\tau = (1.50 \pm 0.11) \times 10^{-12}$ s

$c\tau = 449\ \mu$m

$\tau_{B^+}/\tau_{B^0} = 0.98 \pm 0.09$

B^0-$\overline{B}^0$ mixing parameters

$\chi_d = 0.156 \pm 0.024$

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L} = (0.51 \pm 0.06) \times 10^{12}\ \hbar\ \mathrm{s}^{-1}$

$x_d = \Delta m_{B^0}/\Gamma_{B^0} = 0.71 \pm 0.06$ [a]

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Decays in which the charge of the B is not determined are in the $B^\pm$ section.

Only data from $\Upsilon(4S)$ decays are used for branching fractions, with rare exceptions. The branching fractions listed below assume a 50:50 $B^0\overline{B}^0$:B^+B^- production ratio at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would effect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

Searches for Top and Fourth Generation Hadrons

See the sections "Searches for t Quark" and "Searches for b' (4^{th} Generation) Quark" at the end of the QUARKS section.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Full Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] The $\pi^\pm$ mass has increased by three (old) standard deviations since our 1992 edition, and the π^0 mass, which is determined using the mass difference ($m_{\pi^\pm} - m_{\pi^0}$), has increased accordingly. See the "Note on the Charged Pion Mass" in the $\pi^\pm$ Full Listings for a discussion.

[b] See the "Note on $\pi^\pm \to \ell^\pm\nu\gamma$ and $K^\pm \to \ell^\pm\nu\gamma$ Form Factors" in the $\pi^\pm$ Full Listings for definitions and details.

[c] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ's. Therefore, since no clean separation is possible, we consider the modes with γ's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[d] See the $\pi^\pm$ Full Listings for the energy limits used in this measurement; low-energy γ's are not included.

[e] Derived from an analysis of neutrino-oscillation experiments.

[f] Astrophysical and cosmological arguments give limits of order 10^{-13}; see the π^0 Full Listings.

[g] See the "Note on the Decay Width $\Gamma(\eta \to \gamma\gamma)$" in the η Full Listings.

[h] See the "Note on η Decay Parameters" in the η Full Listings.

[i] C parity forbids this to occur as a single-photon process.

[j] The e^+e^- branching fraction is from $e^+e^- \to \pi^+\pi^-$ experiments only. The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.

[k] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Full Listings for details.

[l] See the "Note on the $f_1(1420)$" in the $f_1(1420)$ Full Listings.

[m] See also the $\omega(1600)$ Full Listings.

[n] See the "Note on the $\eta(1440)$" in the $\eta(1440)$ Full Listings.

[o] See the "Note on the $\rho(1450)$ and the $\rho(1700)$" in the $\rho(1700)$ Full Listings.

[p] See also the $\omega(1420)$ Full Listings.

[q] The value is for the sum of the charge states indicated.

[r] The definition of the slope parameter g of the $K \to 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \to 3\pi$ Decays" in the $K^\pm$ Full Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m^2_{\pi^+} + \cdots .$$

[s] For more details and definitions of parameters see the Full Listings.

[t] See the $K^\pm$ Full Listings for the energy limits used in this measurement.

[u] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[v] Direct-emission branching fraction.

[w] Structure-dependent part.

[x] The *CP*-violation parameters are defined as follows (see also "Note on *CP* Violation in $K_S \to 3\pi$" and "Note on *CP* Violation in K_L^0 Decay" in the Full Listings):

$$\eta_{+-} = |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \to \pi^+\pi^-)}{A(K_S^0 \to \pi^+\pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \to \pi^0\pi^0)}{A(K_S^0 \to \pi^0\pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \to \pi^-\ell^+\nu) - \Gamma(K_L^0 \to \pi^+\ell^-\nu)}{\Gamma(K_L^0 \to \pi^-\ell^+\nu) + \Gamma(K_L^0 \to \pi^+\ell^-\nu)},$$

$$\mathrm{Im}(\eta_{+-0})^2 = \frac{\Gamma(K_S^0 \to \pi^+\pi^-\pi^0)^{CP\ \mathrm{viol.}}}{\Gamma(K_L^0 \to \pi^+\pi^-\pi^0)},$$

$$\mathrm{Im}(\eta_{000})^2 = \frac{\Gamma(K_S^0 \to \pi^0\pi^0\pi^0)}{\Gamma(K_L^0 \to \pi^0\pi^0\pi^0)}.$$

where for the last two relations *CPT* is assumed valid, *i.e.*, $\mathrm{Re}(\eta_{+-0}) \simeq 0$ and $\mathrm{Re}(\eta_{000}) \simeq 0$.

[y] See the K_S^0 Full Listings for the energy limits used in this measurement.

[z] Calculated from K_L^0 semileptonic rates and the K_S^0 lifetime assuming $\Delta S = \Delta Q$.

[aa] ϵ'/ϵ is derived from $|\eta_{00}/\eta_{+-}|$ measurements using theoretical input on phases.

[bb] See the K_L^0 Full Listings for the energy limits used in this measurement.

[cc] $m_{e^+e^-} > 470$ MeV

[dd] Allowed by higher-order electroweak interactions.

[ee] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.

[ff] See the note in the $L(1770)$ Full Listings in Reviews of Modern Physics **56** No. 2 Pt. II (1984), p. S200.

[gg] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in the Full Listings.

[hh] This value combines the e^+ and μ^+ branching fractions, making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence the "e^+." In fact, some of the e^+ measurements already use μ^+ events in this way.

[ii] ℓ indicates e or μ mode, not sum over modes.

[jj] The branching fractions for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Full Listings.

[kk] The two experiments determining this ratio are in serious disagreement. See the Full Listings.

[ll] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[mm] The D_1^0-D_2^0 limits are inferred from the limit on $D^0 \to \overline{D}^0 \to K^+\pi^-$.

[nn] See the "Note on Semileptonic Decays of D and B Mesons" in the D^+ Full Listings for a comparison of inclusive and summed-inclusive branching fractions.

[oo] The limit on $(\overline{K}^*(892)\pi)^- \mu^+\nu_\mu$ just below is much stronger.

[pp] For now, we average together measurements of the $\phi e^+\nu_e$ and $\phi\mu^+\nu_\mu$ branching fractions.

[qq] This branching fraction is calculated from appropriate fractions of the next three branching fractions.

[rr] For admixture of B hadrons at LEP and Tevatron energies.

[ss] These values are model dependent. See note on "Semileptonic Decays" in the B^+ Full Listings.

[tt] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[uu] B^0, B^+, B_s^0, and B baryon states not separated.

[vv] B^0, B^+, and B_s^0 not separated.

[ww] Derived from measurements of χ_d and of Δm_{B^0} times B^0 mean life.

[xx] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.

[yy] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

[zz] Spectroscopic labeling for these states is theoretical, pending experimental information.

Meson Summary Table

See also the table of suggested $q\bar{q}$ quark-model assignments in the Quark Model section.

- • Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.
- † Indicates that the value of J given is preferred, but needs confirmation.

Non-$q\bar{q}$ Candidates

Baryon Summary Table

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3- or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. See our 1986 edition (Physics Letters **170B**) for listings of evidence for Z baryons (KN resonances).

**** Existence is certain, and properties are at least fairly well explored.

*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

** Evidence of existence is only fair.

* Evidence of existence is poor.

Baryon Summary Table

N BARYONS ($S = 0$, $I = 1/2$)

p, $N^+ = uud$; n, $N^0 = udd$

p

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 938.27231 \pm 0.00028$ MeV [a]
$= 1.007276470 \pm 0.000000012$ u
$m_{\overline{p}}/m_p = 0.99999998 \pm 0.00000004$
$|q_p + q_{\overline{p}}|/e < 2 \times 10^{-5}$
$|q_p + q_e|/e < 1.0 \times 10^{-21}$ [b]
Magnetic moment $\mu = 2.79284739 \pm 0.00000006\ \mu_N$
Electric dipole moment $d = (-4 \pm 6) \times 10^{-23}$ e cm
Electric polarizability $\overline{\alpha} = (10.2 \pm 0.9) \times 10^{-4}$ fm^3
Magnetic polarizability $\overline{\beta} = (4.0 \pm 0.9) \times 10^{-4}$ fm^3
Mean life $\tau > 1.6 \times 10^{25}$ years (independent of mode)
$> 10^{31} - 5 \times 10^{32}$ years [c] (mode dependent)

For N decays, p and n distinguish proton and neutron partial lifetimes. See also the "Note on Proton Mean Life Limits" in the Full Listings.

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life and B_i is the branching fraction for the mode in question.

NOTES

This Summary Table only includes established baryons. The Full Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters. The Full Listings also give, where available, pole parameters. See, in particular, the *Note on N and Δ Resonances*.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The *Note on N and Δ Resonances* and the *Note on Λ and Σ Resonances* in the Full Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Full Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

[a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.49432 ± 0.00028 MeV, is less well known than are the masses in u.

[b] The limit is from neutrality-of-matter experiments; it assumes $q_n = q_p + q_e$. See also the charge of the neutron.

[c] The first limit is geochemical and independent of decay mode. The second limit assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray $\overline{p}$'s is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/B(\overline{p} \to e^-\gamma) > 1848$ yr.

[d] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). For reactor experiments with free neutrons, the best limit is $> 10^7$ s.

[e] The parameters g_A, g_V, and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V + g_A\gamma_5) + i(g_{WM}/m_{B_i})\,\sigma_{\lambda\nu}\,q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V = |g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Full Listings.

[f] Time-reversal invariance requires this to be 0° or 180°.

[g] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-\alpha^2}\,\cos\phi\,, \qquad \tan\Delta = -\frac{1}{\alpha}\,\sqrt{1-\alpha^2}\,\sin\phi\,.$$

See the "Note on Baryon Decay Parameters" in the neutron Full Listings.

[h] See the Full Listings for the pion momentum range used in this measurement.

[i] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.

[j] A theoretical value using QED.

[k] The branching fraction includes all the decay modes of the final-state resonance.

[l] The value is for the sum of the charge states indicated.

[m] ℓ indicates e or μ mode, not sum over modes.

SEARCHES FOR FREE QUARKS, MONOPOLES, SUPERSYMMETRY, COMPOSITENESS, etc.

Free Quark Searches

All searches since 1977 have had negative results.

Magnetic Monopole Searches

Isolated candidate events have not been confirmed. Most experiments obtain negative results.

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model.

Assumptions include: 1) $\widetilde{\chi}_1^0$ (or $\widetilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, and all scalar quarks (except $\widetilde{t}_L$ and $\widetilde{t}_R$) are degenerate in mass.

See the Full Listings for a Note giving details of supersymmetry.

$\widetilde{\chi}_i^0$ — neutralinos (mixtures of $\widetilde{\gamma}$, $\widetilde{Z}^0$, and $\widetilde{H}_i^0$)

Mass $m_{\widetilde{\gamma}} > 15$ GeV, CL = 90% [if $m_{\widetilde{f}} = 100$ GeV (from cosmology)]
Mass $m_{\widetilde{\chi}_1^0} > 18$ GeV, CL = 90% [GUT relations assumed]
Mass $m_{\widetilde{\chi}_2^0} > 45$ GeV, CL = 95% [GUT relations assumed]
Mass $m_{\widetilde{\chi}_3^0} > 70$ GeV, CL = 95% [GUT relations assumed]
Mass $m_{\widetilde{\chi}_4^0} > 108$ GeV, CL = 95% [GUT relations assumed]

$\widetilde{\chi}_i^\pm$ — charginos (mixtures of $\widetilde{W}^\pm$ and $\widetilde{H}_i^\pm$)

Mass $m_{\widetilde{\chi}_1^\pm} > 45$ GeV, CL = 95% [all $m_{\widetilde{\chi}_1^0}$]
Mass $m_{\widetilde{\chi}_2^\pm} > 99$ GeV, CL = 95% [GUT relations assumed]

$\widetilde{\nu}$ — scalar neutrino (sneutrino)

Mass $m > 37.1$ GeV, CL = 95% [one flavor]
Mass $m > 41.8$ GeV, CL = 95% [three degenerate flavors]

$\widetilde{e}$ — scalar electron (selectron)

Mass $m > 65$ GeV, CL = 95% [if $m_{\widetilde{\gamma}} = 0$]
Mass $m > 50$ GeV, CL = 95% [if $m_{\widetilde{\gamma}} < 5$ GeV]
Mass $m > 45$ GeV, CL = 95% [if $m_{\widetilde{\chi}_1^0} < 41$ GeV]

$\widetilde{\mu}$ — scalar muon (smuon)

Mass $m > 45$ GeV, CL = 95% [if $m_{\widetilde{\chi}_1^0} < 41$ GeV]

$\widetilde{\tau}$ — scalar tau (stau)

Mass $m > 45$ GeV, CL = 95% [if $m_{\widetilde{\chi}_1^0} < 38$ GeV]

$\widetilde{q}$ — scalar quark (squark)

These limits include the effects of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, $\tan\beta = 2$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}_1^0} \approx m_{\widetilde{g}}/6$.

Mass $m > 90$ GeV, CL = 90% [any $m_{\widetilde{g}} < 410$ GeV]
Mass $m > 218$ GeV, CL = 90% [if $m_{\widetilde{g}} = m_{\widetilde{q}}$]

$\widetilde{g}$ — gluino

There is some controversy about a low-mass window ($1 \lesssim m_{\widetilde{g}} \lesssim 4$ GeV). Several experiments cast doubt on the existence of this window.

These limits include the effects of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, $\tan\beta = 2$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}_1^0} \approx m_{\widetilde{g}}/7$.

Mass $m > 100$ GeV, CL = 90% [any $m_{\widetilde{q}}$]
Mass $m > 218$ GeV, CL = 90% [if $m_{\widetilde{q}} \leq m_{\widetilde{g}}$]

Searches for Quark and Lepton Compositeness

Scale Limits Λ for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \overline{\psi}_L \gamma_\mu \psi_L \overline{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^\pm$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(eeee)$ > 1.6 TeV, CL = 95%
$\Lambda_{LL}^-(eeee)$ > 3.6 TeV, CL = 95%
$\Lambda_{LL}^+(ee\mu\mu)$ > 2.6 TeV, CL = 95%
$\Lambda_{LL}^-(ee\mu\mu)$ > 1.9 TeV, CL = 95%
$\Lambda_{LL}^+(ee\tau\tau)$ > 1.9 TeV, CL = 95%
$\Lambda_{LL}^-(ee\tau\tau)$ > 2.9 TeV, CL = 95%
$\Lambda_{LL}^+(\ell\ell\ell\ell)$ > 3.5 TeV, CL = 95%
$\Lambda_{LL}^-(\ell\ell\ell\ell)$ > 2.8 TeV, CL = 95%
$\Lambda_{LL}^+(eeqq)$ > 1.7 TeV, CL = 95%
$\Lambda_{LL}^-(eeqq)$ > 2.2 TeV, CL = 95%
$\Lambda_{LL}^+(\mu\mu qq)$ > 1.4 TeV, CL = 95%
$\Lambda_{LL}^-(\mu\mu qq)$ > 1.6 TeV, CL = 95%
$\Lambda_{LR}^\pm(\nu_\mu \nu_e \mu e)$ > 3.1 TeV, CL = 90%
$\Lambda_{LL}^\pm(qqqq)$ > 1.4 TeV, CL = 95%

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ-dependent limits assume chiral coupling, except for the third limit for e^* which is for nonchiral coupling. For chiral coupling, this limit corresponds to $\lambda_\gamma = \sqrt{2}$.

$e^{*\pm}$ — excited electron

Mass $m > 46.1$ GeV, CL = 95% (from $e^{*+}e^{*-}$)
Mass $m > 91$ GeV, CL = 95% (if $\lambda_Z > 1$)
Mass $m > 127$ GeV, CL = 95% (if $\lambda_\gamma = 1$)

$\mu^{*\pm}$ — excited muon

Mass $m > 46.1$ GeV, CL = 95% (from $\mu^{*+}\mu^{*-}$)
Mass $m > 91$ GeV, CL = 95% (if $\lambda_Z > 1$)

$\tau^{*\pm}$ — excited tau

Mass $m > 46.0$ GeV, CL = 95% (from $\tau^{*+}\tau^{*-}$)
Mass $m > 90$ GeV, CL = 95% (if $\lambda_Z > 0.18$)

ν^* — excited neutrino

Mass $m > 47$ GeV, CL = 95% (from $\nu^*\overline{\nu}^*$)
Mass $m > 91$ GeV, CL = 95% (if $\lambda_Z > 1$)

q^* — excited quark

Mass $m > 45.6$ GeV, CL = 95% (from $q^*\overline{q}^*$)
Mass $m > 88$ GeV, CL = 95% (if $\lambda_Z > 1$)
Mass $m > 540$ GeV, CL = 95% ($p\overline{p} \rightarrow q^*X$)

Color Sextet and Octet Particles

Color Sextet Quarks (q_6)

Mass $m > 84$ GeV, CL = 95% (Stable q_6)

Color Octet Charged Leptons (ℓ_8)

Mass $m > 86$ GeV, CL = 95% (Stable ℓ_8)

Color Octet Neutrinos (ν_8)

Mass $m > 110$ GeV, CL = 90% ($\nu_8 \rightarrow \nu g$)

Tests of Conservation Laws

TESTS OF CONSERVATION LAWS

Revised by L. Wolfenstein and T.G. Trippe, June 1994.

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full *Review of Particle Properties*, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. The Table is in two parts: "Discrete Space-Time Symmetries," *i.e.*, C, P, T, CP, and CPT; and "Number Conservation Laws," *i.e.*, lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Full Listings in the *Review*. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and $\overline{K}^0$. Any such difference contributes to the CP-violating parameter ϵ. Assuming CPT invariance, ϕ_ϵ, the phase of ϵ should be very close to 44°. (See the "Note on CP Violation in K^0_L Decay" in the Full Listings.) In contrast, if the entire source of CP violation in K^0 decays were a $K^0 - \overline{K}^0$ mass difference, ϕ_ϵ would be 44° + 90°. It is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K^0_L} - m_{K^0_S})\,|\eta|\,(\frac{2}{3}\phi_{+-} + \frac{1}{3}\phi_{00} - \phi_\epsilon)}{\sin\phi_\epsilon}\,.$$

Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0} - m_{K^0})/m_{K^0}| \leq 10^{-18}$ (CL = 90%). Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1 - |\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00} - \phi_{+-}$ provides a measure of CPT violation in $K^0_L \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. So far the only evidence for CP or T violation comes from the measurements of η_{+-}, η_{00}, and the semileptonic decay charge asymmetry for K_L, *e.g.*, $|\eta_{+-}| = |A(K^0_L \to \pi^+\pi^-)/A(K^0_S \to \pi^+\pi^-)| = (2.269 \pm 0.023) \times 10^{-3}$ and $[\Gamma(K^0_L \to \pi^- e^+ \nu) - \Gamma(K^0_L \to \pi^+ e^- \overline{\nu})]/[\text{sum}] = (0.333 \pm 0.014)\%$. Other searches for CP or T violation divide into (a) those that involve weak interactions or parity violation, and (b) those that involve processes allowed by the strong or electromagnetic interactions. In class (a) the most sensitive is probably the search for an electric dipole moment of the neutron, measured to be $< 1.1 \times 10^{-25}$ e cm (95% CL). A nonzero value requires both P and T violation. Class (b) includes the search for C violation in η decay, believed to be an electromagnetic process, *e.g.*, as measured by $\Gamma(\eta \to \mu^+\mu^-\pi^0)/\Gamma(\eta \to \text{all}) < 5 \times 10^{-6}$, and searches for T violation in a number of nuclear and electromagnetic reactions.

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e, muon number L_μ, and tau number L_τ. Searches for violations are of the following types:

a) $\Delta L = 2$ for one type of lepton. The best limit comes from the search for neutrinoless double beta decay $(Z, A) \to (Z + 2, A) + e^- + e^-$. The best laboratory limit is $t_{1/2} > 1.4 \times 10^{24}$ yr (CL=90%) for ^{76}Ge.

b) Conversion of one lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e\gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e\gamma)/\Gamma(\mu \to \text{all}) < 5 \times 10^{-11}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z, A) \to e^- + (Z, A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e\mu$ and $K^+ \to \pi^+ e^- \mu^+$, measured as $\Gamma(K_L \to e\mu)/\Gamma(K_L \to \text{all}) < 3.3 \times 10^{-11}$ and $\Gamma(K^+ \to \pi^+ e^- \mu^+)/\Gamma(K^+ \to \text{all}) < 2.1 \times 10^{-10}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, *e.g.*, $\Gamma(\tau \to \mu\gamma)/\Gamma(\tau \to \text{all}) < 4.2 \times 10^{-6}$ and $\Gamma(\tau \to e\gamma)/\Gamma(\tau \to \text{all}) < 1.2 \times 10^{-4}$.

c) Conversion of one type of lepton into another type of antilepton. The case most studied is $\mu^- + (Z, A) \to e^+ + (Z - 2, A)$, the strongest limit being $\Gamma(\mu^-\text{Ti} \to e^+\text{Ca})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 9 \times 10^{-11}$.

d) Relation to neutrino mass. If neutrinos have mass, then it is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo quark mixing. However, in this case lepton-number-violating processes such as $\mu \to e\gamma$ are expected to have extremely small probability. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental searches. For example, searches for $\overline{\nu}_e$ disappearance, which we label as $\overline{\nu}_e \not\to \overline{\nu}_e$, give measured limits $\Delta(m^2) < 0.0083$ eV^2 for $\sin^2(2\theta) = 1$, and $\sin^2(2\theta) < 0.14$ for large $\Delta(m^2)$, where θ is the neutrino mixing angle. Searches for $\nu_\mu \to \nu_e$ set limits $\Delta(m^2) < 0.09$ eV^2 for $\sin^2(2\theta) = 1$, and $\sin^2(2\theta) < 0.0025$ for large $\Delta(m^2)$. For larger neutrino masses ($\gg 1$ keV), lepton-number violation is searched for by looking for anomalous decays such as $\pi \to e\nu_x$, where ν_x is a massive neutrino. If the $\Delta L = 2$ type of violation occurs, it is expected that neutrinos will have a nonzero mass of the Majorana type.

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, *i.e.* the conversion of a quark of one flavor (d, u, s, c, b, t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

a) $\Delta S = \Delta Q$ rule. In the semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as $\Gamma(\Sigma^+ \to ne^+\nu)/\Gamma(\Sigma^+ \to \text{all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e \nu$, which yields the parameter x, measured to be $(\text{Re}\,x,\ \text{Im}\,x) = (0.006 \pm 0.018,\ -0.003 \pm 0.026)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.

b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S = 2$ via $K^0 - \overline{K}^0$ mixing, which is directly measured by $m(K_S) - m(K_L) = (3.510 \pm 0.018) \times 10^{-12}$ MeV. There

is now evidence for $B^0 - \overline{B}^0$ mixing ($\Delta B = 2$), with the corresponding mass difference between the eigenstates $(m_{B^0_H} - m_{B^0_L}) = (0.71 \pm 0.06)\ \Gamma_B = (3.1 \pm 0.4) \times 10^{-10}$ MeV. No evidence exists for $D^0 - \overline{D}^0$ mixing, which is expected to be much smaller in the Standard Model.

c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+\mu^-)/\Gamma(K_L \to \text{all}) = (7.4 \pm 0.4) \times 10^{-9}$ puts limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from a limit on $K^+ \to \pi^+\nu\overline{\nu}$, which occurs in the Standard Model only as a second-order weak process with a branching fraction of (1 to 8)$\times 10^{-10}$. The current limit is $\Gamma(K^+ \to \pi^+\nu\overline{\nu})/\Gamma(K^+ \to \text{all}) < 5.2 \times 10^{-9}$. Limits for charm-changing or bottom-changing neutral currents are much less stringent: $\Gamma(D^0 \to \mu^+\mu^-)/\Gamma(D^0 \to \text{all}) < 1.1 \times 10^{-5}$ and $\Gamma(B^0 \to \mu^+\mu^-)/\Gamma(B^0 \to \text{all}) < 5.9 \times 10^{-6}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model.

Limits are given at the 90% confidence level, while errors are given as ± 1 standard deviation.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Full Listings an ideogram of the measurements. For more about S, see the Introduction.

[a] Positronium data are from A.P. Mills and S. Berko, Physical Review Letters **18** 420 (1967); and K. Marko and A. Rich, Physical Review Letters **33** 980 (1974). Values for 90% confidence level, are from A.P. Mills, private communication.

[b] C parity forbids this to occur as a single-photon process.

[c] Time-reversal invariance requires this to be 0° or 180°.

[d] Allowed by higher-order electroweak interactions.

[e] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

[f] ϵ'/ϵ is derived from $|\eta_{00}/\eta_{+-}|$ measurements using theoretical input on phases.

[g] Neglecting photon channels. See, *e.g.*, A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).

[h] Derived from measured values of ϕ_{+-}, ϕ_{00}, $|\eta|$, $\tau_{K^0_S}$, and $|m_{K^0_L} - m_{K^0_S}|$, as described in the introduction to this Table.

[i] The value is for the sum of the charge states indicated.

[j] A test of additive vs. multiplicative lepton family number conservation.

[k] ℓ means a sum over e and μ modes.

[l] $\Delta(m^2) = 100\ \text{eV}^2$.

[m] $190\ \text{eV}^2 < \Delta(m^2) < 320\ \text{eV}^2$.

[n] Derived from an analysis of neutrino-oscillation experiments.

[o] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). For reactor experiments with free neutrons, the best limit is $> 10^7$ s.

[p] This is the best "electron disappearance" limit. The best limit for the mode $e^- \to \nu\gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).

[q] The D^0_1-D^0_2 limits are inferred from the limit on $D^0 \to \overline{D}^0 \to K^+\pi^-$.

[r] See the K^0_L Full Listings for the energy limits used in this measurement.

[s] $m_{e^+e^-} > 470$ MeV.

[t] B^0, B^+, and B^0_s not separated.

1. PHYSICAL CONSTANTS

Table 1.1. Reviewed 1993 by B.N. Taylor, NIST. Based mainly on the "1986 Adjustment of the Fundamental Physical Constants" by E.R. Cohen and B.N. Taylor, Rev. Mod. Phys. **59**, 1121 (1987). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding uncertainties in parts per million (ppm) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology).

Since the 1986 adjustment, new experiments have yielded improved values for a number of constants, including the Rydberg constant R_∞, the Planck constant h, the fine-structure constant α, and the molar gas constant R, and hence also for constants directly derived from these, such as the Boltzmann constant k and Stefan-Boltzmann constant σ. The new results and their impact on the 1986 recommended values are discussed extensively in "Recommended Values of the Fundamental Physical Constants: A Status Report," B.N. Taylor and E.R. Cohen, J. Res. Natl. Inst. Stand. Technol. **95**, 497 (1990); see also E.R. Cohen and B.N. Taylor, "The Fundamental Physical Constants," Phys. Today, August 1993 Part 2, BG9. In general, the new results give uncertainties for the affected constants that are 5 to 7 times smaller than the 1986 uncertainties, but the changes in the values themselves are smaller than twice the 1986 uncertainties. Because the output values of a least-squares adjustment are correlated, the new results cannot readily be incorporated with the 1986 values. Until the next complete adjustment of the constants, the 1986 CODATA set, given (in part) below, remains the set of choice.

Quantity	Symbol, equation	Value	Uncert. (ppm)

* The meter is defined to be the length of path traveled by light in vacuum in 1/299 792 458 s. See B.W. Petley, Nature **303**, 373 (1983).

† At $Q^2 = 0$. At $Q^2 \approx m_W^2$ the value is approximately 1/128.

‡ See discussion in Sec. 26 "Standard Model of electroweak interactions."

2. ASTROPHYSICAL CONSTANTS

Table 2.1. Written and revised with the help of K.R. Lang, K.A. Olive, J. Primack, S. Rudaz, E. M. Standish, Jr., and M.S. Turner. The figures in parentheses after some values give the 1-standard deviation uncertainties in the last digit(s). While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference.

Quantity	Symbol, equation	Value	Reference

5. 1 AU divided by $\pi/648\,000$; quoted error is from the JPL Planetary Ephemerides value of the AU [4].
6. Heliocentric gravitational constant from Ref. 3 times $2/c^2$. The given 9-place accuracy appears to be consistent with uncertainties in actually defining the earth's orbital parameters.
7. Obtained from the heliocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation quoted for G_N.
8. It is surprisingly difficult to find a definitive value for this important constant. In all cases, the solar luminosity is calculated as $4\pi \times (1\ \mathrm{AU})^2$ times the solar constant (or total solar irradiance, TSI). The luminosity given is reduced from TSI $= 1367.51 \pm 0.01$ W m^{-2}, obtained from SMM/ACRIMI spacecraft measurements during the interval 2/80–6/89 [23]. While the time constant for energy production by the sun is very long, radiation from the surface might be modulated or otherwise modified by sunspots; this has apparently not been taken into account. Accordingly, we quote 4-place accuracy. We do not know the actual error, but suppose it might be 5 or 10 in the last place. Sackmann *et al.* [24] use TSI $= 1370 \pm 2$ W m^{-2}, but conclude that the solar luminosity ($L_\odot = 3.853 \times 10^{26}$ J s^{-1}) has an uncertainty of 1.5%. Their value is based on three 1977–83 papers, and they comment that the error is based on scatter among the reported values, which is substantially in excess of that expected from the individual quoted errors. The conclusion of the 1971 review by Thekaekara and Drummond [25] ($1353 \pm 1\%$ W m^{-2}) is often quoted [26], and a luminosity based on this value was tabulated in the last two editions of this Review. The conversion to luminosity is not given in the Thekaekara and Drummond paper, and we cannot exactly reproduce the solar luminosity given in Ref. 26. Finally, a value based on the 1954 spectral curve due to Johnson [27] ($1395 \pm 1\%$ W m^{-2}, or $L_\odot = 3.92 \times 10^{26}$ J s^{-1}) has been used widely, and may be the basis for higher value of the solar luminosity and corresponding lower value of the solar absolute bolometric magnitude (4.72) still common in the literature [10].
9. Obtained from the geocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation quoted for G_N.

3. BIG-BANG COSMOLOGY

Revised November 1993 by K.A. Olive.

At early times, and today on a sufficently large scale, our Universe is very nearly homogeneous and isotropic. The most general space-time metric for a homogeneous, isotropic space is the Friedmann-Robertson-Walker metric (with $c = 1$) [1,2,3]:

$$ds^2 = dt^2 - R^2(t)\left[\frac{dr^2}{1-\kappa r^2} + r^2\,(d\theta^2 + \sin^2\theta\, d\phi^2)\right] . \tag{3.1}$$

$R(t)$ is a scale factor for distances in comoving coordinates. With appropriate rescaling of the corrdinates, κ can be chosen to be $+1$, -1, or 0, corresponding to closed, open, or spatially flat geometries. Einstein's equations lead to the Friedmann equation

$$H^2 \equiv \left(\frac{\dot R}{R}\right)^2 = \frac{8\pi\, G_N\, \rho}{3} - \frac{\kappa}{R^2} + \frac{\Lambda}{3} , \tag{3.2}$$

as well as to

$$\frac{\ddot R}{R} = \frac{\Lambda}{3} - \frac{4\pi G_N}{3}\,(\rho + 3p) , \tag{3.3}$$

where $H(t)$ is the Hubble parameter, ρ is the total mass-energy density, p is the isotropic pressure, and Λ is the cosmological constant. (For limits on Λ, see the Table of Astrophysical Constants; we will assume here $\Lambda = 0$.) The Friedmann equation serves to define the density parameter Ω_0 (subscript 0 indicates present-day values):

$$\kappa/R_0^2 = H_0^2(\Omega_0 - 1) , \qquad \Omega_0 = \rho_0/\rho_c ; \tag{3.4}$$

and the critical density is defined as

$$\rho_c \equiv \frac{3H^2}{8\pi\, G_N} = 1.88 \times 10^{-29}\, h^2 \text{ g cm}^{-3} , \tag{3.5}$$

with

$$H_0 = 100\, h_0 \text{ km s}^{-1} \text{ Mpc}^{-1} = h_0/(9.78 \text{ Gyr}) . \tag{3.6}$$

Observational bounds give $0.4 < h_0 < 1$. The three curvature signatures $\kappa = +1, -1$, and 0 correspond to $\Omega_0 > 1$, < 1, and $= 1$. Knowledge of Ω_0 is even poorer than that of h_0. Luminous matter (stars and associated material) contribute $\Omega_{\rm lum} \leq 0.01$. There is no lack of evidence for copious amounts of dark matter: rotation curves of spiral galaxies, virial estimates of cluster masses, gravitational lensing by clusters and individual galaxies, and so on. The minimum amount of dark matter required to explain the flat rotation curves of spiral galaxies only amounts to $\Omega_0 \sim 0.1$, while estimates for Ω_0 based upon cluster virial masses suggests $\Omega_0 \sim 0.2 - 0.4$. The highest estimates for the mass density come from studies of the peculiar motions of galaxies (including our own); estimates for Ω_0 obtained by relating peculiar velocity measurements to the distribution galaxies within a few hundred Mpc approach unity. A conservative range for the mass density is: $0.1 \leq \Omega_0 \leq 2$. The excess of Ω_0 over $\Omega_{\rm lum}$ leads to the inference that most of the matter in the Universe is nonluminous dark matter.

In an expanding universe, the wavelength of light emitted from a distant source is shifted towards the red. The redshift z is defined such that $1 + z$ is the ratio of the detected wavelength (λ) to emitted (laboratory) wavelength (λ_e) of some electromagnetic spectral feature. It follows from the metric given in Eq. (3.1) that

$$1 + z = \lambda/\lambda_e = R_0/R_e \tag{3.7}$$

where R_e is the value of the scale factor at the time the light was emitted. For light emitted in the not too distant past, one can expand R_e and write $R_e \simeq R_0 + (t_e - t_0)\dot R_0$. For small (compared to H_0^{-1}) $\Delta t = (t_e - t_0)$, Eq. (3.7) takes the form of Hubble's law

$$z \approx \Delta t \frac{\dot R_0}{R_0} \approx \ell H_0 , \tag{3.8}$$

where ℓ is the distance to the source.

Energy conservation implies that

$$\dot\rho = -3(\dot R/R)(\rho + p) , \tag{3.9}$$

so that for a matter-dominated ($p = 0$) universe $\rho \propto R^{-3}$, while for a radiation-dominated ($p = \rho/3$) universe $\rho \propto R^{-4}$. Thus the less singular curvature term κ/R^2 in the Friedmann equation can be neglected at early times when R is small. If the Universe expands adiabatically, the entropy per comoving volume ($\equiv R^3 s$) is constant, where the entropy density is $s = (\rho + p)/T$ and T is temperature. The energy density of radiation can be expressed (with $\hbar = c = 1$) as

$$\rho_r = \frac{\pi^2}{30} N(T)(kT)^4 , \tag{3.10}$$

where $N(T)$ counts the effectively massless degrees of freedom of bosons and fermions:

$$N(T) = \sum_B g_B + \frac{7}{8}\sum_F g_F . \tag{3.11}$$

For example, for $m_\mu > kT > m_e$, $N(T) = g_\gamma + 7/8\,(g_e + 3g_\nu) = 2 + 7/8\,[4 + 3(2)] = 43/4$. For $m_\pi > kT > m_\mu$, $N(T) = 57/4$. At temperatures less than about 1 MeV, neutrinos have decoupled from the thermal background, *i.e.*, the weak interaction rates are no longer fast enough compared with the expansion rate to keep neutrinos in equilibrium with the remaining thermal bath consisting of $\gamma, e^\pm$. Furthermore, at temperatures $kT < m_e$, by entropy conservation, the ratio of the neutrino temperature to the photon temperature is given by $(T_\nu/T_\gamma)^3 = g_\gamma/(g_\gamma + \frac{7}{8} g_e) = 4/11$.

In the early Universe when $\rho \approx \rho_r$, then $\dot R \propto 1/R$, so that $R \propto t^{1/2}$ and $Ht \to 1/2$ as $t \to 0$. The time-temperature relationship at very early times can then be found from the above equations:

$$t = \frac{2.42}{\sqrt{N(T)}}\left(\frac{1\text{ MeV}}{kT}\right)^2 \text{ sec} . \tag{3.12}$$

At later times, since the energy density in radiation falls off as R^{-4} and the energy density in non-relativistic matter falls off as R^{-3}, the Universe eventually became matter dominated. The epoch of matter-radiation density equality is determined by equating the matter density at $t_{\rm eq}$, $\rho_m = \Omega_0\rho_c(R_0/R_{\rm eq})^3$ to the radiation density, $\rho_r = (\pi^2/30)[2 + (21/4)(4/11)^{4/3}](kT_0)^4(R_0/R_{\rm eq})^4$ where T_0 is the present temperature of the microwave background (see below). Solving for $(R_0/R_{\rm eq}) = 1 + z_{\rm eq}$ gives

$$\begin{aligned} z_{\rm eq} + 1 &= \Omega_0 h_0^2/4.2 \times 10^{-5} = 2.4 \times 10^4\, \Omega_0 h_0^2 ; \\ kT_{\rm eq} &= 5.6\, \Omega_0 h_0^2\, \text{eV} ; \\ t_{\rm eq} &\approx 0.39(\Omega_0 H_0^2)^{-1/2}(1 + z_{\rm eq})^{-3/2} \\ &= 3.2 \times 10^{10}(\Omega_0 h_0^2)^{-2}\, \text{sec} . \end{aligned} \tag{3.13}$$

Prior to this epoch the density was dominated by radiation (relativistic particles; see Eq. (3.10)), and at later epochs matter density dominated. Atoms formed at $z \approx 1300$, and by $z_{\rm dec} \approx 1100$ the free electron density was low enough that space became essentially transparent to photons and matter and radiation were decoupled. These are the photons observed in the microwave background today.

The age of the Universe today, t_0, is related to both the Hubble parameter and the value of Ω_0 (still assuming that $\Lambda = 0$). In the standard model, $t_0 \gg t_{\rm eq}$ and we can write

$$t_0 = H_0^{-1}\int_0^1 \left(1 - \Omega_0 + \Omega_0 x^{-1}\right)^{-1/2} dx . \tag{3.14}$$

Constraints on t_0 yield constraints on the combination $\Omega_0 h_0^2$. For example, $t_0 \geq 13 \times 10^9$ yr implies that $\Omega_0 h_0^2 \leq 0.25$ for $h_0 \geq 0.5$,

or $\Omega_0 h_0^2 \leq 0.45$ for $h_0 \geq 0.4$, while $t_0 \geq 10 \times 10^9$ yr implies that $\Omega_0 h_0^2 \leq 0.8$ for $h_0 \geq 0.5$, or $\Omega_0 h_0^2 \leq 1.1$ for $h_0 \geq 0.4$.

The present temperature of the microwave background is $T_0 = 2.726 \pm 0.005$ K as measured by COBE [4], and the number density of photons $n_\gamma = (2\zeta(3)/\pi^2)(kT_0)^3 \approx 411$ cm^{-3}. The energy density in photons (for which $g_\gamma = 2$) is $\rho_\gamma = (\pi^2/15)(kT_0)^4$. At the present epoch, $\rho_\gamma = 4.65 \times 10^{-34}$ g cm^{-3} $= 0.26$ eV cm^{-3}. For nonrelativistic matter (such as baryons) today, the energy density is $\rho_B = m_B n_B$ with $n_B \propto R^{-3}$, so that for most of the history of the Universe n_B/s is constant. Today, the entropy density is related to the photon density by $s = (4/3)(\pi^2/30)[2 + (21/4)(4/11)](kT_0)^3 = 7.0\, n_\gamma$. Big Bang nucleosynthesis calculations limit $\eta = n_B/n_\gamma$ to $2.8 \times 10^{-10} \leq \eta \leq 4.0 \times 10^{-10}$. The parameter η is also related to the portion of Ω in baryons

$$\Omega_B = 3.66 \times 10^7 \eta\, h_0^{-2}\, (T_0/2.726\ \mathrm{K})^3\ , \tag{3.15}$$

so that $0.010 < \Omega_B\, h_0^2 < 0.015$, and hence the Universe cannot be closed by baryons.

4. DARK MATTER

Written September 1989 by R. Flores and K.A. Olive. Revised November 1991 and November 1993.

There is increasing evidence for the existence of large quantities of dark matter in the Universe. The most direct evidence comes from the astronomical observation of the motion of visible matter (stars and regions of neutral hydrogen gas) in galaxies. The observed velocities due to rotational motion in spiral galaxies are measured to be largely independent of the distance to the center of these galaxies [1](they are said to have "flat rotational curves"). In the absence of any unseen component, we would expect that the velocity falls off with increasing distance, $v^2 \approx G_N M_{\rm vis}/r$. In contrast, a flat rotation curve implies a total mass $M_{\rm tot} \approx G_N^{-1}\, v_{\rm obs}^2 r$ [$\approx 10^{11} M_\odot\ (v_{\rm obs}/200\ {\rm km\ s^{-1}})^2\ (r/10\ {\rm kpc})$] in excess of the visible mass $M_{\rm vis}$. It can be inferred from these observations that there exists a dark matter component distributed in a (roughly) spherical halo about the galaxy. The dynamics of groups of galaxies and clusters, as well as the presence of very hot gas in elliptical galaxies require large quantities of unseen matter as well [2]. More recent observations of hot x-ray emitting gas in clusters of galaxies [3], and of gravitational lensing of high redshift background galaxies by foreground clusters [4] (which do not require the cluster to be relaxed), also indicate the presence of dark matter on cluster scales. In addition, theories of cosmological inflation predict that the density parameter of the Universe $\Omega_{\rm tot} = 1$, whereas standard Big Bang nucleosynthesis requires $\Omega_{\rm baryon} \lesssim 0.1$ [5]. This implies the existence of nonbaryonic dark matter. Further indirect evidence comes from our theoretical understanding of the growth of density perturbations as seeds for galaxy formation. Without the presence of dark matter, it is very difficult to reconcile the existence of galaxies (and quasars) at high redshifts with the new measurements by COBE of the anisotropy of the microwave background radiation [6]. Perturbations in baryon density can grow only after the time of recombination, *i.e.* when the baryons decouple from the microwave background. When $\Omega_{\rm tot} = 1$ due to dark matter, matter domination occurs much earlier and dark matter perturbations grow for a longer period, thus avoiding a conflict with the magnitude of the microwave background anisotropy.

In our own galaxy, the distribution of the visible matter and its observed circular motion determine the local (solar neighborhood) dark matter density $\rho^{\rm DM} \approx 0.3$ GeV cm^{-3} [7]. Regardless of the nature of the dark matter, it must behave as a collisionless gas, with a broad velocity distribution (typically assumed to be Maxwellian); $\langle v \rangle \approx \triangle v \approx 300$ km s^{-1}.

We do not know the identity of the dark matter nor whether there is more than one type of dark matter. Baryons are difficult to conceal [8] and in the standard Big Bang model cannot make up all of the dark matter if $\Omega_{\rm tot} = 1$. By the same token, by comparing the lower limit of $\Omega_{\rm baryon} \gtrsim 0.01$ from nucleosynthesis [5], it is very likely that some of the baryons are dark. Though it is theoretically unlikely that galactic halos could be made of very dim objects, such as low-mass stars with masses $\lesssim 0.1 M_\odot$, recent gravitational microlensing searches for such objects may have a positive detection [9] (these objects are sometimes referred to as MACHOS, massive compact halo objects). There are several theoretical elementary particle candidates (WIMPs, weakly interacting massive particles) that could explain the existence of dark matter, of which the most commonly discussed are: a neutrino (if massive), a neutralino (from supersymmetry), and the axion (from the strong CP problem). These are summarized in Table 4.1.

Table 4.1: Dark Matter Candidates

Type	Candidate	Possible mass
Hot	neutrino	1–10 eV
Cold	neutralino: photino, Higgsino, or bino	20–350 GeV
Cold	axion	10^{-5}–10^{-3} eV

Regardless of the exact identity of the dark matter (DM), its kinetic energy at the time when dark-matter domination begins determines the subsequent evolution of the density perturbations that seed galactic and large structures [10]. If the dark matter is relativistic (hot dark matter, HDM) only the largest (supercluster) structures survive and they must fragment to form galactic structure, whereas if it is nonrelativistic (cold dark matter, CDM), structure on all scales is preserved. The large-scale distribution of matter in n-body simulations of a HDM-dominated universe is not compatible with observations (unless there are point-like density perturbations), whereas a flat CDM-dominated universe requires that the visible matter be predominantly concentrated in the denser regions of the DM distribution (biased galaxy formation). In point of fact, both the HDM- and CDM-dominated universes have some degree of difficulty with the size of the microwave background anisotropy measured by COBE. A mixture of cold and hot dark matter may provide a better solution to the problem of generating large scale structures. An example of such a mixture would be a ν_τ with a mass of order a few eV *and* a more massive neutralino.

For a cold dark matter particle species with equal particle (X) and antiparticle ($\overline{X}$) densities (except for the axions), its cosmological density at present is [11]

$$\Omega_X h^2 \approx 1.6 \times 10^{-10}\, N_F^{1/2}\, (T_X/T_\gamma)^3 \times \left(a + \tfrac{1}{12} b\, \langle v^2 \rangle_f\right)^{-1} \langle v^2 \rangle_f^{-1} \qquad (4.1)$$

with a and b determined from the (velocity averaged) annihilation cross section, expanded in powers of momentum, $\langle v\, \sigma_{X\overline{X}} \rangle = a + \frac{1}{6} b\, \langle v^2 \rangle_f$, at freezeout temperature T_f ($\langle v^2 \rangle_f = 6 T_f / M_X$) at which the X's drop from thermal equilibrium (typically $T_f \approx \frac{1}{20} M_X$). In Eq. (4.1), N_F is the total number of relativistic degrees of freedom at T_f and (T_X/T_γ) is the ratio of the temperatures of X's and photons at T_f. In the halo of our galaxy $\langle v^2 \rangle \approx 10^{-6}$, thus $\langle v\, \sigma_{X\overline{X}} \rangle_{\rm halo}$ and Ω_X are closely related.

Several proposals or experiments exist to detect cold dark matter candidates. For the case of heavy ($M \gtrsim 1$ GeV) particles, elastic scattering from nuclei would produce nuclear recoils with energies of $\gtrsim 1$ keV, and several techniques have been proposed to detect these recoils. The expected collision rate for a target nucleus mass m_N is:

$$R = 4.3\ {\rm kg^{-1}\ day^{-1}} \left(\frac{1\ {\rm GeV^2}}{m_N\, m_x}\right)\left(\frac{\sigma_{\rm el}}{10^{-38}\ {\rm cm^2}}\right) \times \left(\frac{\rho^{\rm DM}}{0.3\ {\rm GeV\ cm^{-3}}}\right)\left(\frac{\langle |v_E| \rangle}{300\ {\rm km\ s^{-1}}}\right), \qquad (4.2)$$

where $\langle |v_E| \rangle$ is the average velocity at which they strike the detector. Since crossing symmetry relates $\sigma_{\rm el}$ to $\sigma_{X\overline{X}}$, R is closely related to Ω_X. Dirac neutrinos (and sneutrinos) with masses 0.012–4.7 TeV have already been excluded by searches done using double-β decay detectors [12]. Axions could be detected by their expected coherent conversion to microwave photons in a tuned cavity. Products of DM annihilation in the halo (*e.g.*, cosmic ray $\overline{p}$'s, e^+'s, γ's) and the core of the Sun (ν's) would indirectly signal the existence of particle DM. The absence of a signal in high energy solar-ν searches using underground detectors rules out sneutrinos whereas cosmic ray searches do not constrain theory so far. Experimental limits concerning a number of dark matter candidates are given in the Full Listings. See the index under "Dark matter limits."

Recent LEP results when combined with the above experimental constraints now completely eliminate massive 4th-generation neutrinos or sneutrinos as dark matter candidates. Sneutrinos and additional Dirac and Majorana neutrinos with masses $\lesssim 40$ GeV are excluded by LEP. This alone eliminates a Majorana neutrino, since the relic abundance for the neutrinos with masses $\gtrsim 40$ GeV would be $\Omega h^2 \lesssim 2 \times 10^{-3}$, making them cosmologically uninteresting. In the case of Dirac neutrinos, if there were a density asymmetry between ν and $\overline{\nu}$, it would in principle be possible to have a cosmologically interesting density even though $m_\nu > 40$ GeV. However, as described

in the previous paragraph, Dirac neutrinos (and sneutrinos) below 4.7 TeV are ruled out by direct cold dark matter searches.

σ_T, σ_I, λ_T, and λ_I are energy dependent. Values quoted apply to high energy range given in footnote *a* or *b*, where energy dependence is weak.

a. σ_{total} at 80–240 GeV for neutrons ($\approx\sigma$ for protons) from Murthy *et al.*, Nucl. Phys. **B92**, 269 (1975). This scales approximately as $A^{0.77}$.

b. $\sigma_{\text{inelastic}} = \sigma_{\text{total}} - \sigma_{\text{elastic}} - \sigma_{\text{quasielastic}}$; for neutrons at 60–375 GeV from Roberts *et al.*, Nucl. Phys. **B159**, 56 (1979). For protons and other particles, see Carroll *et al.*, Phys. Lett. **80B**, 319 (1979); note that $\sigma_I(p) \approx \sigma_I(n)$. σ_I scales approximately as $A^{0.71}$.

c. Mean free path between collisions (λ_T) or inelastic interactions (λ_I), calculated from $\lambda = A/(N\times\sigma)$, where N is Avogadro's number.

d. For minimum-ionizing heavy particles (muons, pions, protons, *etc.*). Minimum dE/dx calculated in 1994, using density effect correction coefficients from R. M. Sternheimer, M. J. Berger, and S. M. Seltzer, Atomic Data and Nuclear Data Tables **30**, 261–271 (1984). For electrons and positrons see S.M. Seltzer and M.J. Berger, Int. J. Appl. Radiat. **35**, 665–676 (1984). Ionization energy loss is discussed in Sec. 10.

e. From Y.S. Tsai, Rev. Mod. Phys. **46**, 815 (1974); X_0 data for all elements up to uranium may be found here. Corrections for molecular binding applied for H_2 and D_2. Parentheses refer to gaseous form at STP (0°C, 1 atm.).

f. Values for solids, or the liquid phase at boiling point, except as noted. Refractive index given for sodium D line.

g. For pure graphite; industrial graphite density may vary 2.1–2.3 g/cm^3.

h. Standard shielding blocks, typical composition O_2 52%, Si 32.5%, Ca 6%, Na 1.5%, Fe 2%, Al 4%, plus reinforcing iron bars. The attenuation length, $\ell = 115\pm5$ g/cm^2, is also valid for earth (typical $\rho = 2.15$), from CERN-LRL-RHEL Shielding exp., UCRL-17841 (1968).

i. Density may vary about ±3%, depending on operating conditions.

j. Values for typical working conditions with H_2 target: 50 mole percent, 29°K, 7 atm.

k. Typical scintillator; *e.g.*, PILOT B and NE 102A have an atomic ratio H/C = 1.10.

ℓ. Main components: 80% SiO_2 + 12% B_2O_3 + 5% Na_2O.

m. For typical fused quartz; density may vary. The specific gravity of crystalline quartz is 2.64.

n. Solid ethane density at −60°C; gaseous refractive index at 0°C, 546 mm pressure.

o. $n(SiO_2) + 2n(H_2O)$ used in Čerenkov counters, ρ = density in g/cm^3. From M. Cantin *et al.*, Nucl. Instr. and Meth. **118**, 177 (1974).

p. G10-plate, typical 60% SiO_2 and 40% epoxy.

Table 7.1. Revised 1993. The atomic number (top left) is the number of protons in the nucleus. The atomic mass (bottom) is weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of the carbon-12 isotope, defined to be exactly 12 unified atomic mass units (u). Errors range from 1 to 9 in the last digit quoted. Relative isotopic abundances often vary considerably, both in natural and commercial samples. A number in parentheses is the mass of the longest-lived isotope of that element—no stable isotope exists. However, although Th, Pa, and U have no stable isotopes, they do have characteristic terrestrial compositions, and meaningful weighted masses can be given. Adapted from "Atomic Weights of the Elements 1991," Pure and Applied Chemistry **64**, 1519 (1992), and G. Audi and A.H. Wapstra, "The 1993 Mass Evaluation," Nucl. Phys. **A565**, 1 (1993). The names for elements 104–109 have been adopted by the American Chemical Society Nomenclature Committee, and recommended to IUPAC.

8. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 8.1. Reviewed 1993 by W.C. Martin, NIST. The electronic configurations and ionization energies here are taken from the *CRC Handbook of Chemistry and Physics*, 74^{th} Edition, ed. D.R. Lide (CRC Press, Boca Raton, FL, 1993). The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six $3d$ electrons and two $4s$ electrons. The ionization energy is the least energy necessary to remove to infinity one electron from an *atom* of the element.

	Element		Electron configuration ($3d^5$ = five $3d$ electrons, *etc.*)		Ground state $^{2S+1}L_J$	Ionization energy (eV)
1	H	Hydrogen	$1s$		$^2S_{1/2}$	13.5984
2	He	Helium	$1s^2$		$^1S_0$	24.5874
3	Li	Lithium	(He) $2s$		$^2S_{1/2}$	5.3917
4	Be	Beryllium	(He) $2s^2$		$^1S_0$	9.3226
5	B	Boron	(He) $2s^2$ $2p$		$^2P_{1/2}$	8.2980
6	C	Carbon	(He) $2s^2$ $2p^2$		$^3P_0$	11.2603
7	N	Nitrogen	(He) $2s^2$ $2p^3$		$^4S_{3/2}$	14.5341
8	O	Oxygen	(He) $2s^2$ $2p^4$		$^3P_2$	13.6181
9	F	Fluorine	(He) $2s^2$ $2p^5$		$^2P_{3/2}$	17.4228
10	Ne	Neon	(He) $2s^2$ $2p^6$		$^1S_0$	21.5645
11	Na	Sodium	(Ne) $3s$		$^2S_{1/2}$	5.1391
12	Mg	Magnesium	(Ne) $3s^2$		$^1S_0$	7.6462
13	Al	Aluminum	(Ne) $3s^2$ $3p$		$^2P_{1/2}$	5.9858
14	Si	Silicon	(Ne) $3s^2$ $3p^2$		$^3P_0$	8.1517
15	P	Phosphorus	(Ne) $3s^2$ $3p^3$		$^4S_{3/2}$	10.4867
16	S	Sulfur	(Ne) $3s^2$ $3p^4$		$^3P_2$	10.3600
17	Cl	Chlorine	(Ne) $3s^2$ $3p^5$		$^2P_{3/2}$	12.9676

9. HIGH-ENERGY COLLIDER PARAMETERS: e^+e^- Colliders (I)

The numbers here were received from representatives of the colliders in 1993 or early 1994. Quantities are, where appropriate, r.m.s. H and V indicate horizontal and vertical directions. Many of the numbers of course change over the lifetime of a collider; only the latest values are given here.

10. PASSAGE OF PARTICLES THROUGH MATTER

Revised June 1994.

10.1. Notation

Table 10.1: The notation and values given in Table 1.1 are used. The kinematic variables β and γ have the usual meanings. Definitions of other variables used in this section are summarized below.

Symbol	Definition	Units or Value
α	Fine structure constant	$1/137.035\,989\,5(61)$
M	Incident particle mass	MeV/c^2
E	Incident particle energy γMc^2	MeV
T	Kinetic energy	MeV
$m_e c^2$	Electron mass $\times$ c^2	0.510 999 06(15) MeV
r_e	Classical electron radius $e^2/4\pi\epsilon_0 c^2$	2.817 940 92(38) fm
N_A	Avogadro's number	$6.022\,136\,7(36) \times 10^{23}$ mol^{-1}
ze	Charge of incident particle	
Z	Atomic number of medium	
A	Atomic mass of medium	g mol^{-1}
K/A	$4\pi N_A r_e^2 m_e c^2/A$	0.307 075 MeV g^{-1} cm^2 for $A = 1$ g mol^{-1}
δ	Density effect correction to ionization energy loss	
$\hbar\omega_p$	Plasma energy $\sqrt{4\pi N_e r_e^3}\, m_e c^2/\alpha$	$= 28.816\sqrt{\rho\langle Z/A\rangle}$ eV[a]
w_j	Fraction by weight of the jth element in a compound or mixture	
n_j	$\propto$ number of jth kind of atoms in a compound or mixture	
X_0	Radiation length	MeV g^{-1} cm^2
E_c	Critical energy	MeV
E_s	Scale energy $\sqrt{4\pi/\alpha}\, m_e c^2$	21.2052 MeV
R_M	Molière radius	MeV g^{-1} cm^2

[a] For ρ in g cm^{-3}.

10.2. Ionization energy loss by heavy particles [1–5]

Moderately relativistic charged particles other than electrons lose energy in matter primarily by ionization. If the incident particle velocity βc is larger than that of orbital electrons ($\sim Z\alpha c$) and small enough that radiative effects do not dominate (for example, pion energy smaller than 100–200 GeV in iron), then the mean rate of energy loss (or stopping power) is given by the Bethe-Bloch equation,

$$-\frac{dE}{dx} = Kz^2\frac{Z}{A}\frac{1}{\beta^2}\left[\frac{1}{2}\ln\frac{2m_e c^2\beta^2\gamma^2 T_{\max}}{I^2} - \beta^2 - \frac{\delta}{2}\right] . \qquad (10.1)$$

Here $T_{\max}$ is the maximum kinetic energy which can be imparted to a free electron in a single collision, and the other variables are defined in Table 10.1. The units are chosen so that dx is measured in mass per unit area, *e.g.*, in g cm^{-2}. The function as computed for pions on copper is shown by the solid curve in Fig. 10.1, and for pions on other materials in Fig. 10.2. A minor dependence on M at the highest energies is introduced through $T_{\max}$, but for all practical purposes in high-energy physics dE/dx in a given material is a function only of β. Except in hydrogen, particles of the same velocity have very similar rates of energy loss in different materials; there is a slow decrease in the rate of energy loss with increasing Z. The qualitative difference in stopping power behavior at high energies between a gas (He) and the other materials shown in Fig. 10.2 is due to the density effect correction, δ, discussed below. The stopping power functions are characterized by broad minima whose position drops from $\beta\gamma = 3.5$ to 3.0 as Z goes from 7 to 100.

In practical cases, most relativistic particles (*e.g.*, cosmic-ray muons) have energy loss rates close to the minimum, and are said to be minimum ionizing particles, or mip's.

Eq. (10.1) may be integrated to find the total range R for a particle which loses energy only through ionization. Since dE/dx depends only on β, R/M is a function of E/M or pc/M. In practice, range is a useful concept only for low-energy hadrons ($R \lesssim \lambda_I$, where λ_I is the nuclear interaction length), and for muons below a few hundred GeV (above which radiative effects dominate). R/M as a function of $\beta\gamma = pc/M$ is shown for a variety of materials in Fig. 10.3.

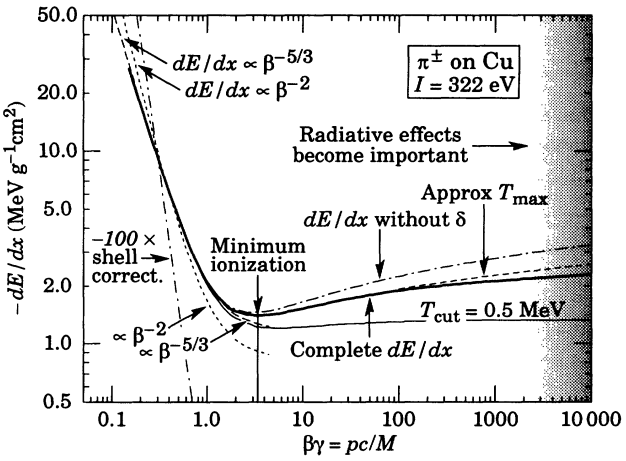

Figure 10.1: Energy loss rate in copper. The function without the density effect correction is also shown, as is the shell correction and two low-energy approximations.

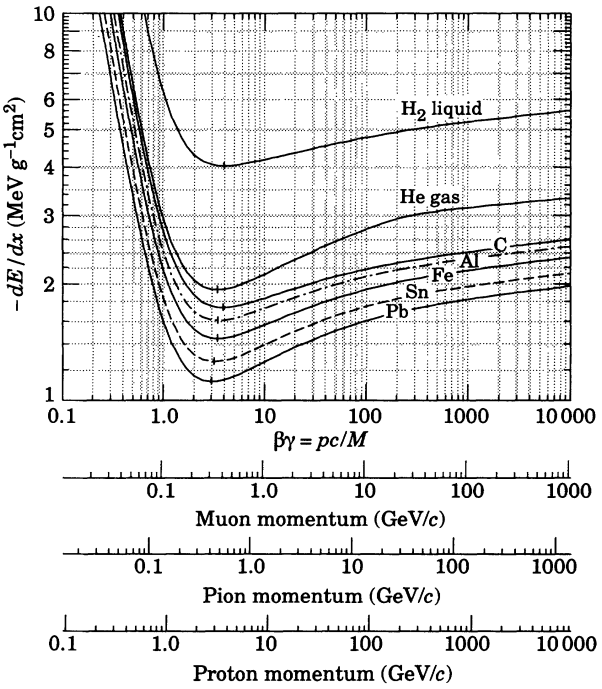

Figure 10.2: Energy loss rate in liquid (bubble chamber) hydrogen, gaseous helium, carbon, aluminum, tin, and lead.

For a point-like charged particle with mass M and momentum $M\beta\gamma$, $T_{\max}$ is given by

$$T_{\max} = \frac{2m_e c^2\,\beta^2\gamma^2}{1 + 2\gamma m_e/M + (m_e/M)^2} . \qquad (10.2)$$

It is usual [1,2] to make the low-energy approximation $T_{\max} = 2m_e c^2\,\beta^2\gamma^2$, valid for $2\gamma m_e/M \ll 1$; this, in fact, is done implicitly in many standard references. For pion in copper, the error thus introduced into dE/dx is greater than 6% at 100 GeV. The correct expression should be used.

At such energies, the maximum 4-momentum transfer to the electron can exceed 1 GeV/c, where structure effects significantly

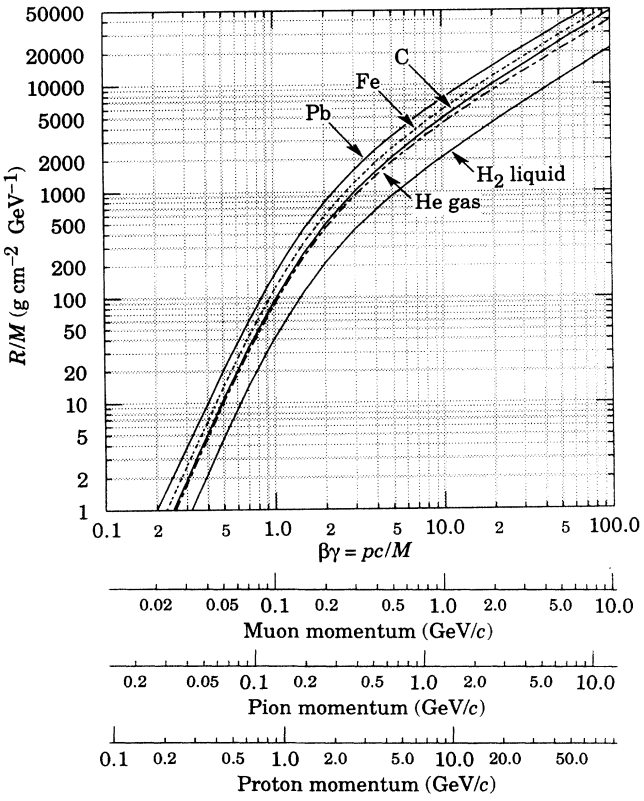

Figure 10.3: Range of heavy charged particles in liquid (bubble chamber) hydrogen, helium gas, carbon, iron, and lead. For example: For a K^+ whose momentum is 700 MeV/c, $\beta\gamma = 1.42$. For lead we read $R/M \approx 396$, and so the range is 195 g cm^{-2}.

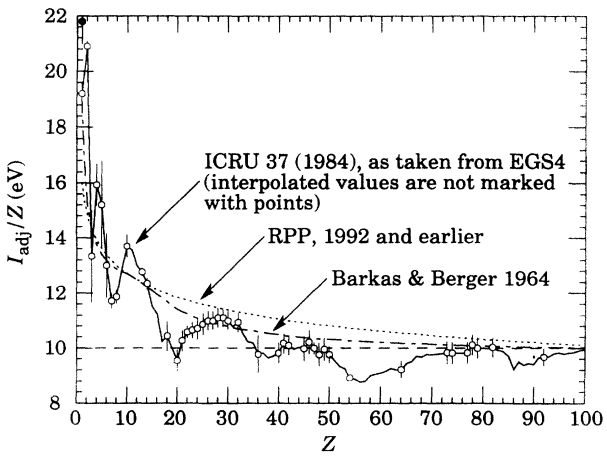

Figure 10.4: Excitation energies (divided by Z) as adopted by the ICRU [7]. Those based on measurement are shown by points with error flags; the interpolated values are simply joined. The solid point is for liquid H_2; the open point at 19.2 is for H_2 gas. Also shown are curves based on two approximate formulae.

modify the cross sections. This problem has been investigated by J.D. Jackson [6], who concluded that corrections to dE/dx are negligible below energies where radiative effects dominate. While the cross section for rare hard collisions is modified, the average stopping power, dominated by many softer collisions, is almost unchanged.

The mean excitation energy I is 10 ± 1 eV for elements heavier than oxygen. The values adopted by the ICRU for the chemical elements [7] are now in wide use; these are shown in Fig. 10.4. Machine-readable versions can also be found [8]. Given the availability of these constants and their variation with atomic structure, there seems little point to depending upon approximate formulae, as was done in the past.

A shell correction is often included in the square brackets of Eq. (10.1) [3,5,7], to correct for atomic binding having been neglected in calculating some of the contributions to Eq. (10.1). We show the Barkas form [3] in Fig. 10.1. For copper it contributes about 1% at $\beta\gamma = 0.3$ (kinetic energy 6 MeV for a pion), and the correction decreases very rapidly with energy. While it is negligible for high-energy physics applications, this and other low-energy corrections must be taken into account at lower energies, such as those encountered in medical physics.

As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (10.1) increases as $\ln\beta\gamma$. However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic rise [4,9–13]. At very high energies,

$$\delta/2 \to \ln(\hbar\omega_p/I) + \ln\beta\gamma - 1/2\,, \qquad (10.3)$$

where $\delta/2$ is the density effect correction introduced in Eq. (10.1) and $\hbar\omega_p$ is the plasma energy defined in Table 10.1. A comparison with Eq. (10.1) shows that $|dE/dx|$ then grows as $\ln\beta\gamma$ rather than $\ln\beta^2\gamma^2$, and that the mean excitation energy I is replaced by the plasma energy $\hbar\omega_p$. The stopping power as calculated with and without the density effect correction is shown in Fig. 10.1. Since the plasma frequency scales as the square root of the electron density, the correction is much larger for a liquid or solid than for a gas, as is illustrated by the examples in Fig. 10.2.

The remaining relativistic rise can be attributed to large energy transfers to a few electrons. If these escape or are otherwise accounted for separately, the energy deposited in an absorbing layer (in contrast to the energy lost by the particle) approaches a constant value, the Fermi plateau (see Sec. 10.3 below). The curve in Fig. 10.1 labeled "$T_{\rm cut} = 0.5$ MeV" illustrates this behavior. At extreme energies (*e.g.*, 400 GeV for muons or pions in iron), radiative effects become important. These are especially relevant for high-energy muons, as discussed in Sec. 10.9.

For particles moving more slowly than atomic electrons, the above discussion is inapplicable. At velocities $\alpha z \gtrsim \beta \gtrsim 10^{-3}$ or slightly lower, the total energy-loss rate is proportional to β, and non-ionizing nuclear recoil energy loss contributes substantially to the total [14]. For protons in silicon, $|dE/dx| = 61.2\beta$ GeV cm^2 g^{-1} for $\beta < 0.005$; the peak occurs at $\beta = 0.0126$, where $|dE/dx| = 522$ MeV cm^2 g^{-1}. In neutron-scattering experiments, light output in scintillator has been observed for recoil protons with energies as low as 30 eV [15].

It is often stated that for $\beta \gtrsim z/137$, $|dE/dx|$ falls as β^{-2} before reaching the broad minimum at $\beta\gamma \approx 3.0$–3.5. In fact, the slope is nowhere this great, and $|dE/dx| \propto \beta^{-5/3}$ provides a very good approximation to the actual function out to $\beta\gamma > 1$. This behavior is shown in Fig. 10.1, along with the traditional β^{-2} proportionality.

The quantity $(dE/dx)\delta x$ is the mean energy loss via interaction with electrons in a layer of the medium with thickness δx. For finite δx, there are fluctuations in the actual energy loss. The distribution is skewed toward high values (the Landau tail) [1,16]. Only for a thick layer [$(dE/dx)\delta x \gg 2m_e c^2\,\beta^2\gamma^2$] is the distribution nearly Gaussian. The large fluctuations in the energy loss are due to the small number of collisions involving large energy transfers. The fluctuations are smaller for the so-called restricted energy loss rate, as discussed in Sec. 10.3 below.

A mixture or compound can be thought of as made up of thin layers of pure elements in the right proportion (Bragg additivity). In this case,

$$\frac{dE}{dx} = \sum w_j \left.\frac{dE}{dx}\right|_j\,, \qquad (10.4)$$

where $dE/dx|_j$ is the mean rate of energy loss (in MeV g cm^{-2}) in the jth element. Eq. (10.1) can be inserted into Eq. (10.4) to find expressions for $\langle Z/A\rangle$, $\langle I\rangle$, and $\langle\delta\rangle$; for example, $\langle Z/A\rangle =$

$\sum w_j Z_j/A_j = \sum n_j Z_j / \sum n_j A_j$. However, $\langle I \rangle$ as defined this way is an underestimate, because in a compound electrons are more tightly bound than in the free elements, and $\langle \delta \rangle$ as calculated this way has little relevance, because it is the electron density which matters. If possible, one uses the tables given in Refs. 13 and 12, which include effective excitation energies and interpolation coefficients for calculating the density effect correction for the chemical elements and nearly 200 mixtures and compounds. If a compound or mixture is not found, then one uses the recipe for δ given in Ref. 10 (or Ref. 8), and calculates $\langle I \rangle$ according to the discussion in Ref. 11. (Note the "13%" rule!)

Ionization losses by electrons and positrons [12] are not discussed here. Above the critical energy, which is a few tens of MeV in most materials, bremsstrahlung is the dominant source of energy loss. This important case is discussed below. The contributions of various electron energy-loss processes in lead are shown in Fig. 11.4.

10.3. Restricted energy loss rates for relativistic ionizing particles

Fluctuations in energy loss are due mainly to the production of a few high-energy knock-on electrons. Practical detectors often measure the energy *deposited*, not the energy *lost*. When energy is carried off by energetic knock-on electrons, it is more appropriate to consider the mean energy loss excluding energy transfers greater than some cutoff $T_{\rm cut}$. The restricted energy loss rate is

$$-\left.\frac{dE}{dx}\right|_{T<T_{\rm cut}} = Kz^2\frac{Z}{A}\frac{1}{\beta^2}\left[\frac{1}{2}\ln\frac{2m_ec^2\beta^2\gamma^2T_{\rm upper}}{I^2} - \frac{\beta^2}{2}\left(1+\frac{T_{\rm upper}}{T_{\rm max}}\right) - \frac{C}{Z} - \frac{\delta}{2}\right] \tag{10.5}$$

where $T_{\rm upper} = {\rm MIN}(T_{\rm cut}, T_{\rm max})$. This form agrees with the equation given in previous editions of this *Review* [17] for $T_{\rm cut} << T_{\rm max}$ but smoothly joins the normal Bethe-Bloch function (Eq. (10.1)) for $T_{\rm cut} > T_{\rm max}$.

10.4. Energetic knock-on electrons (δ rays)

The distribution of secondary electrons with kinetic energies $T \gg I$ is given by [1]

$$\frac{d^2N}{dTdx} = \frac{1}{2}Kz^2\frac{Z}{A}\frac{1}{\beta^2}\frac{F(T)}{T^2} \tag{10.6}$$

for $I \ll T \leq T_{\rm max}$, where $T_{\rm max}$ is given by Eq. (10.2). The factor F is spin-dependent, but is about unity for $T \ll T_{\rm max}$. For spin-0 particles $F(T) = (1 - \beta^2 T/T_{\rm max})$; forms for spins 1/2 and 1 are also given by Rossi [1]. When Eq. (10.6) is integrated from $T_{\rm cut}$ to $T_{\rm max}$, one obtains the difference between Eq. (10.1) and Eq. (10.5). For incident electrons, the indistinguishability of projectile and target means that the range of T extends only to half the kinetic energy of the incident particle. Additional formulae are given in Ref. 18. Equation (10.6) is inaccurate for T close to I: for $2I \lesssim T \lesssim 10I$, the $1/T^2$ dependence above becomes approximately $T^{-\eta}$, with $3 \lesssim \eta \lesssim 5$ [19].

10.5. Ionization yields

Physicists frequently relate total energy loss to the number of ion pairs produced near the particle's track. This relation becomes complicated for relativistic particles due to the wandering of energetic knock-on electrons whose ranges exceed the dimensions of the fiducial volume. For a qualitative appraisal of the nonlocality of energy deposition in various media by such modestly energetic knock-on electrons, see Ref. 20. The mean local energy dissipation per local ion pair produced, W, while essentially constant for relativistic particles, increases at slow particle speeds [21]. For gases, W can be surprisingly sensitive to trace amounts of various contaminants [21]. Furthermore, ionization yields in practical cases may be greatly influenced by such factors as subsequent recombination [22].

10.6. Multiple scattering through small angles

A charged particle traversing a medium is deflected by many small-angle scatters. Most of this deflection is due to Coulomb scattering from nuclei, and hence the effect is called multiple Coulomb scattering. (However, for hadronic projectiles, the strong interactions also contribute to multiple scattering.) The Coulomb scattering distribution is well represented by the theory of Molière [23]. It is roughly Gaussian for small deflection angles, but at larger angles (greater than a few θ_0, defined below) it behaves like Rutherford scattering, having larger tails than does a Gaussian distribution.

If we define

$$\theta_0 = \theta^{\rm rms}_{\rm plane} = \frac{1}{\sqrt{2}}\theta^{\rm rms}_{\rm space} \, . \tag{10.7}$$

then it is sufficient for many applications to use a Gaussian approximation for the central 98% of the projected angular distribution, with a width given by [24,25]

$$\theta_0 = \frac{13.6\ {\rm MeV}}{\beta cp}\, z\sqrt{x/X_0}\left[1 + 0.038\ln(x/X_0)\right] \, . \tag{10.8}$$

Here p, βc, and z are the momentum, velocity, and charge number of the incident particle, and x/X_0 is the thickness of the scattering medium in radiation lengths (defined below). This value of θ_0 is from a fit to Molière distribution [23] for singly charged particles with $\beta = 1$ for all Z, and is accurate to 11% or better for $10^{-3} < x/X_0 < 100$.

Eq. (10.8) describes scattering from a single material, while the usual problem involves the multiple scattering of a particle traversing many different layers and mixtures. Since it is from a fit to a Molière distribution, it is incorrect to add the individual θ_0 contributions in quadrature; the result is systematically too small. It is much more accurate to apply Eq. (10.8) once, after finding x and X_0 for the combined scatterer.

Lynch and Dahl have extended this phenomenological approach, fitting Gaussian distributions to a variable fraction of the Molière distribution for arbitrary scatterers [25], and achieve accuracies of 2% or better.

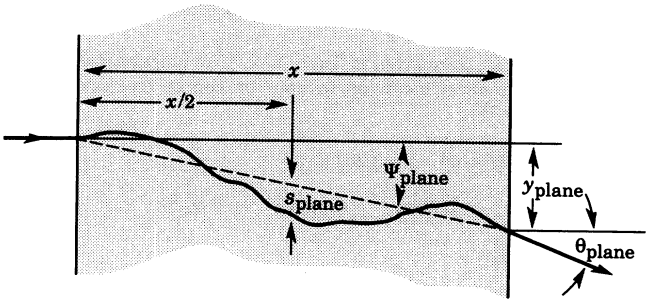

Figure 10.5: Quantities used to describe multiple Coulomb scattering. The particle is incident in the plane of the figure.

The nonprojected (space) and projected (plane) angular distributions are given approximately by [23]

$$\frac{1}{2\pi\theta_0^2}\exp\left(-\frac{\theta^2_{\rm space}}{2\theta_0^2}\right)d\Omega \, , \tag{10.9}$$

$$\frac{1}{\sqrt{2\pi}\,\theta_0}\exp\left(-\frac{\theta^2_{\rm plane}}{2\theta_0^2}\right)d\theta_{\rm plane} \, , \tag{10.10}$$

where θ is the deflection angle. In this approximation, $\theta^2_{\rm space} \approx (\theta^2_{{\rm plane},x} + \theta^2_{{\rm plane},y})$, where the x and y axes are orthogonal to the direction of motion, and $d\Omega \approx d\theta_{{\rm plane},x}\, d\theta_{{\rm plane},y}$. Deflections into $\theta_{{\rm plane},x}$ and $\theta_{{\rm plane},y}$ are independent and identically distributed.

Figure 10.5 shows these and other quantities sometimes used to describe multiple Coulomb scattering. They are

$$\psi^{\rm rms}_{\rm plane} = \frac{1}{\sqrt{3}}\theta^{\rm rms}_{\rm plane} = \frac{1}{\sqrt{3}}\theta_0 \, , \tag{10.11}$$

$$y_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x\,\theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x\,\theta_0 \ , \tag{10.12}$$

$$s_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x\,\theta_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x\,\theta_0 \ . \tag{10.13}$$

All the quantitative estimates in this section apply only in the limit of small $\theta_{\text{plane}}^{\text{rms}}$ and in the absence of large-angle scatters. The random variables s, ψ, y, and θ in a given plane are distributed in a correlated fashion (see Sec. 16.1 of this *Review* for the definition of the correlation coefficient). Obviously, $y \approx x\psi$. In addition, y and θ have the correlation coefficient $\rho_{y\theta} = \sqrt{3}/2 \approx 0.87$. For Monte Carlo generation of a joint $(y_{\text{plane}}, \theta_{\text{plane}})$ distribution, or for other calculations, it may be most convenient to work with independent Gaussian random variables (z_1, z_2) with mean zero and variance one, and then set

$$\begin{aligned} y_{\text{plane}} &= z_1\, x\,\theta_0 (1-\rho_{y\theta}^2)^{1/2}/\sqrt{3} + z_2\,\rho_{y\theta} x\,\theta_0/\sqrt{3} \\ &= z_1\, x\,\theta_0/\sqrt{12} + z_2\, x\,\theta_0/2 \ ; \end{aligned} \tag{10.14}$$

$$\theta_{\text{plane}} = z_2\,\theta_0 \ . \tag{10.15}$$

Note that the second term for y_{plane} equals $x\,\theta_{\text{plane}}/2$ and represents the displacement that would have occurred had the deflection θ_{plane} all occurred at the single point $x/2$.

For heavy ions the multiple Coulomb scattering has been measured and compared with various theoretical distributions [26].

10.7. Radiation length and associated quantities

In dealing with electrons and photons at high energies, it is convenient to measure the thickness of the material in units of the radiation length X_0. This is the mean distance over which a high-energy electron loses all but $1/e$ of its energy by bremsstrahlung, and is the appropriate scale length for describing high-energy electromagnetic cascades. X_0 has been calculated and tabulated by Y.S. Tsai [27]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A}\left\{ Z^2 \left[L_{\text{rad}} - f(Z) \right] + Z\, L'_{\text{rad}} \right\} \ , \tag{10.16}$$

where L_{rad} and L'_{rad} are given in Table 10.2. The function $f(Z)$ is an infinite sum, but for elements up to uranium can be represented to 4-place accuracy by

$$\begin{aligned} f(Z) = a^2 \big[&(1+a^2)^{-1} + 0.20206 \\ &- 0.0369\, a^2 + 0.0083\, a^4 - 0.002\, a^6 \big] \ , \end{aligned} \tag{10.17}$$

where $a = \alpha Z$ [28].

Table 10.2: Tsai's L_{rad} and L'_{rad}, for use in calculating the radiation length in an element using Eq. (10.16).

Element	Z	L_{rad}	L'_{rad}
H	1	5.31	6.144
He	2	4.79	5.621
Li	3	4.74	5.805
Be	4	4.71	5.924
Others	> 4	$\ln(184.15\, Z^{-1/3})$	$\ln(1194\, Z^{-2/3})$

Although it is easy to use Eq. (10.16) to calculate X_0, the functional dependence on Z is somewhat hidden. Dahl provides a compact fit to the data [29]:

$$X_0 = \frac{716.4 \text{ g cm}^{-2}\, A}{Z(Z+1)\ln(287/\sqrt{Z})} \tag{10.18}$$

Results obtained with this formula agree with Tsai's values to better than 2.5% for all elements except helium, where the result is about 5% low.

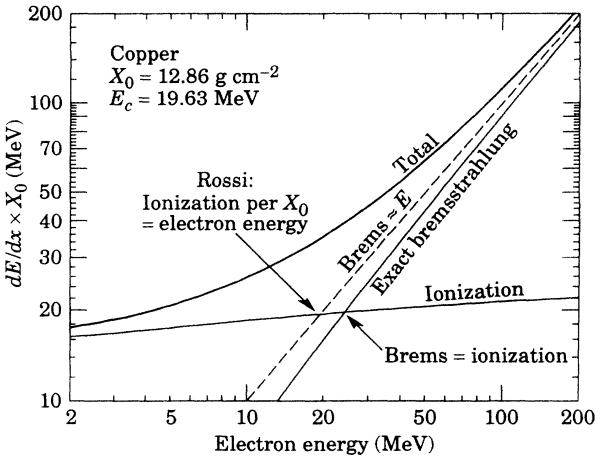

Figure 10.6: Two definitions of the critical energy E_c.

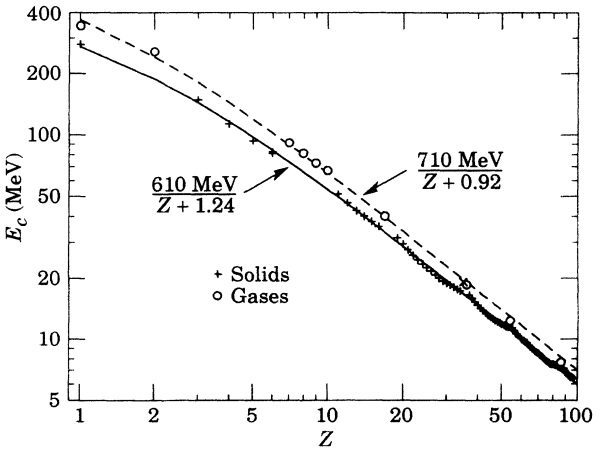

Figure 10.7: Critical energy for the chemical elements, using Rossi's definition [1]. The fits shown are for solids and liquids (solid line) and gases (dashed line). The rms deviation is 2.2% for the solids and 4.0% for the gases.

The radiation length in a mixture or compound may be approximated by

$$1/X_0 = \sum w_j/X_j \ , \tag{10.19}$$

where w_j and X_j are the fraction by weight and the radiation length for the ith element.

An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The *critical energy* E_c is sometimes defined as the energy at which the two loss rates are equal [30]. Berger and Seltzer [30] also give the approximation $E_c = (800 \text{ MeV})/(Z + 1.2)$. This formula has been widely quoted, and has been given in previous editions of this *Review* [17]. Among alternate definitions is that of Rossi [1], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation $|dE/dx|_{\text{brems}} \approx E/X_0$. These definitions are illustrated in the case of copper in Fig. 10.6 [31].

The accuracy of approximate forms for E_c has been limited by the failure to distinguish between gases and solid or liquids, where there is a substantial difference in ionization at the relevant energy because of the density effect. We distinguish these two cases in Fig. 10.7. Fits

were also made with functions of the form $a/(Z+b)^{\alpha}$, but α was essentially unity.

The transverse development of electromagnetic showers in different materials scales fairly accurately with the *Molière radius* R_M, given by [32,33]

$$R_M = X_0 E_s/E_c \ , \tag{10.20}$$

where $E_s \approx 21$ MeV (see Table 10.1), and the Rossi definition of E_c is used.

In a material containing a weight fraction w_j of the element with critical energy E_{cj} and radiation length X_j, the Molière radius is given by

$$\frac{1}{R_M} = \frac{1}{E_s}\sum \frac{w_j E_{cj}}{X_j} \ . \tag{10.21}$$

For very high-energy photons, the total e^+e^- pair-production cross section is approximately

$$\sigma = \tfrac{7}{9}(A/X_0 N_A) \ , \tag{10.22}$$

where A is the atomic weight of the material and N_A is Avogadro's number. Equation Eq. (10.22) is accurate to within a few percent down to energies as low as 1 GeV. The cross section decreases at lower energies, as shown in Fig. 11.4 of this *Review*. As the energy decreases, a number of other processes become important, as is shown in Fig. 11.3 of this *Review*.

10.8. Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energy. The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is therefore convenient to introduce the scale variables

$$t = x/X_0$$

$$y = E/E_c \ , \tag{10.23}$$

so that distance is measured in units of radiation length and energy in units of critical energy.

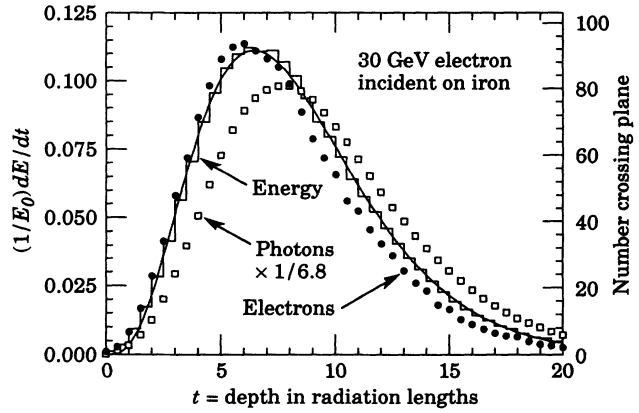

Figure 10.8: An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution. Circles indicate the number of electrons with total energy greater than 1.5 MeV crossing planes at $X_0/2$ intervals (scale on right) and the squares the number of photons with $E \geq 1.5$ MeV crossing the planes (scaled down to have same area as the electron distribution).

Longitudinal profiles for an EGS4 [8] simulation of a 30 GeV electron-induced cascade in iron are shown in Fig. 10.8. The number of particles crossing a plane (very close to Rossi's Π function [1]) is sensitive to the cutoff energy, here chosen as a total energy of 1.5 MeV for both electrons and photons. The electron number falls off more quickly than energy deposition. This is because, with increasing depth, a larger fraction of the cascade energy is carried by photons. Exactly what a calorimeter measures depends on the device, but it is not likely to be exactly any of the profiles shown. In gas counters it may be very close to the electron number, but in glass Čerenkov detectors and other devices with "thick" sensitive regions it is closer to the energy deposition (total track length). In such detectors the signal is proportional to the "detectable" track length T_d, which is in general less than the total track length T. Practical devices are sensitive to electrons with energy above some detection threshold E_d, and $T_d = T\,F(E_d/E_c)$. An analytic form for $F(E_d/E_c)$ obtained by Rossi [1] is given by Fabjan [34]; see also Amaldi [35].

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [36]:

$$\frac{dE}{dt} = E_0\, b\, \frac{(bt)^{a-1}e^{-bt}}{\Gamma(a)} \tag{10.24}$$

The maximum $t_{\max}$ occurs at $(a-1)/b$. We have made fits to shower profiles in elements ranging from carbon to uranium, at energies from 1 GeV to 100 GeV. The energy deposition profiles are well described by Eq. (10.24) with

$$t_{\max} = (a-1)/b = 1.0 \times (\ln y + C_j) \ , \qquad j = e, \gamma \ , \tag{10.25}$$

where $C_e = -0.5$ for electron-induced cascades and $C_\gamma = +0.5$ for photon-induced cascades. To use Eq. (10.24), one finds $(a-1)/b$ from Eq. (10.25) and Eq. (10.23), then finds a either by assuming $b \approx 0.5$ or by finding a more accurate value from Fig. 10.9. The results are very similar for the electron number profiles, but there is some dependence on the atomic number of the medium. A similar form for the electron number maximum was obtained by Rossi in the context of his "Approximation B," [1] (see Fabjan's review in Ref. 34), but with $C_e = -1.0$ and $C_\gamma = -0.5$; we regard this as superseded by the EGS4 result.

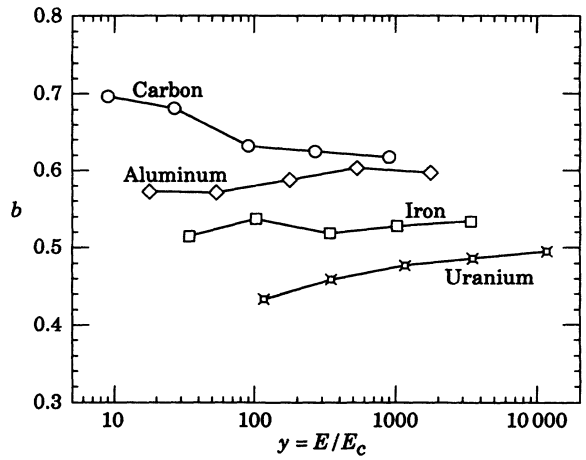

Figure 10.9: Fitted values of the scale factor b for energy deposition profiles obtained with EGS4 for a variety of elements for incident electrons with $1 \leq E_0 \leq 100$ GeV. Values obtained for incident photons are essentially the same.

The "shower length" $X_s = X_0/b$ is less conveniently parametrized, since b depends upon both Z and incident energy, as shown in Fig. 10.9. As a corollary of this Z dependence, the number of electrons crossing a plane near shower maximum is underestimated using Rossi's

approximation for carbon and seriously overestimated for uranium. Essentially the same b values are obtained for incident electrons and photons. For many purposes it is sufficient to take $b \approx 0.5$.

The gamma distribution is very flat near the origin, while the EGS4 cascade (or a real cascade) increases more rapidly. As a result Eq. (10.24) fails badly for about the first two radiation lengths; it was necessary to exclude this region in making fits.

Because fluctuations are important, Eq. (10.24) should be used only in applications where average behavior is adequate. Grindhammer *et al.* have developed fast simulation algorithms in which the variance and correlation of a and b are obtained by fitting Eq. (10.24) to individually simulated cascades, then generating profiles for cascades using a and b chosen from the correlated distributions [37].

Measurements of the lateral distribution in electromagnetic cascades are shown in Refs. 32 and 33. On the average, only 10% of the energy lies outside the cylinder with radius R_M. About 99% is contained inside of $3.5R_M$, but at this radius and beyond composition effects become important and the scaling with R_M fails. The distributions are characterized by a narrow core, and broaden as the shower develops. They are often represented as the sum of two Gaussians, and Grindhammer [37] describes them with the function

$$f(r) = \frac{2r\,R^2}{(r^2+R^2)^2}\ , \tag{10.26}$$

where R is a phenomenological function of x/X_0 and $\ln E$.

10.9. Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. For muons and pions in materials such as iron, this "critical energy" occurs at several hundred GeV. Radiative effects dominate the energy loss of energetic muons found in cosmic rays or produced at the newest accelerators. These processes are characterized by small cross sections, hard spectra, large energy fluctuations, and the associated generation of electromagnetic and (in the case of photonuclear interactions) hadronic showers. As a consequence, at these energies the treatment of energy loss as a uniform and continuous process is for many purposes inadequate.

It is convenient to write the average rate of muon energy loss as [38]

$$-dE/dx = a(E) + b(E)\,E\ . \tag{10.27}$$

Here $a(E)$ is the ionization energy loss given by Eq. (10.1), and $b(E)$ is the sum of e^+e^- pair production, bremsstrahlung, and photonuclear contributions. To the approximation that these slowly-varying functions are constant, the mean range x_0 of a muon with initial energy E_0 is given by

$$x_0 \approx (1/b)\ln(a + bE_0)\ . \tag{10.28}$$

Figure 10.10 shows contributions to $b(E)$ for iron. Since $a(E) \approx 0.002$ GeV g^{-1} cm^2, $b(E)E$ dominates the energy loss above several hundred GeV, where $b(E)$ is nearly constant. The rate of energy loss for muons in hydrogen, uranium, and iron is shown in Fig. 10.11 [39].

QED calculations of cross sections for bremsstrahlung and e^+e^- pair production have long been known, but were much improved around 1970 to meet the needs of cosmic ray physics [40–44]. Rozental showed that the screened atomic electron contribution could be included by replacing Z^2 with $Z(Z+1.2)$ in the nuclear bremsstrahlung cross sections and by $Z(Z+1.3)$ in the case of e^+e^- pair production [45], and that other corrections might reduce the cross section by as much as 5%. We take this as the present uncertainty. Cross sections for both processes have been evaluated independently by Tsai [27].

A comparison of various improvements to the Bethe-Heitler formula is given by Wright [46]. For muon energies above 100 GeV, $\mu^+\mu^-$ pair production is also possible. This process is potentially troublesome because it can lead to charge misassignment, but it contributes less than 0.01% to the the total energy loss [39].

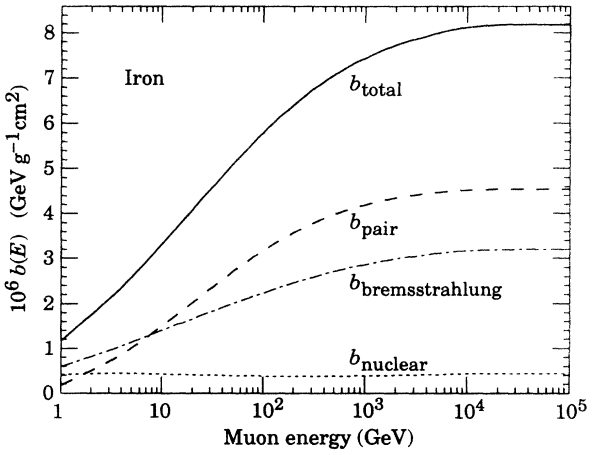

Figure 10.10: Contributions to the fractional energy loss by muons in iron due to e^+e^- pair production, bremsstrahlung, and photonuclear interactions, as obtained from Lohmann *et al.* [39].

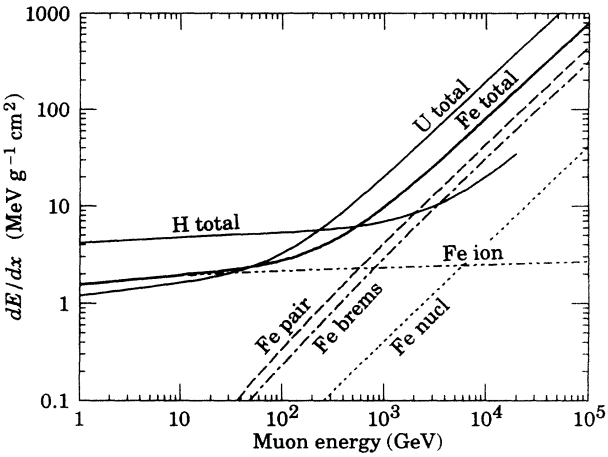

Figure 10.11: The average energy loss of a muon in hydrogen, iron, and uranium as a function of muon energy. Contributions to dE/dx in iron from ionization and the processes shown in Fig. 10.10 are also shown.

Photonuclear interactions account for about 5% of the total energy loss of high-energy muons in iron, and for about 2% in uranium [47]. The losses are concentrated in rare, relatively hard events.

These radiative cross sections are expressed as functions of the fractional energy loss ν. The bremsstrahlung cross section goes roughly as $1/\nu$ over most of the range, while for the pair production case the distribution goes as ν^{-3} to ν^{-2} (see Ref. 48). "Hard" losses are therefore more probable in bremsstrahlung, and in fact energy losses due to pair production may very nearly be treated as continuous. The momentum distribution of an incident 1 TeV/c muon beam after it crosses 3 m of iron is shown in Fig. 10.12. The most probable loss is 9 GeV, or 3.8 MeV g^{-1}cm^2. The full width at half maximum is 7 GeV/c, or 0.7%. The radiative tail is almost entirely due to bremsstrahlung; this includes most of the 10% that lost more than 2.8% of their energy. Most of the 3.3% that lost more than 10% of their incident energy experienced photonuclear interactions. The latter can exceed nominal detector resolution [49], necessitating the reconstruction of lost energy. Electromagnetic and hadronic cascades in detector materials can obscure muon tracks in detector planes and reduce tracking efficiency [50].

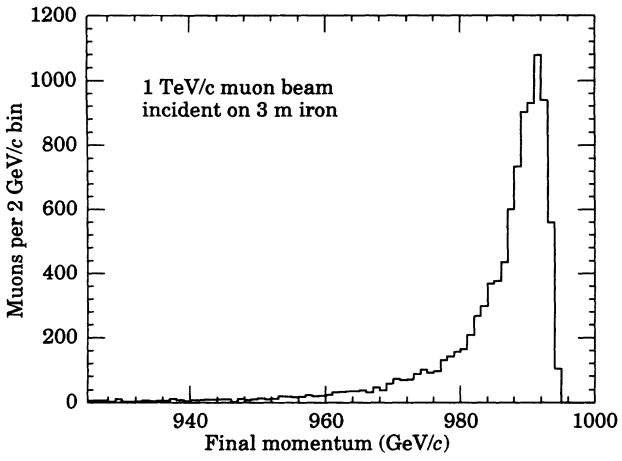

Figure 10.12: The momentum distribution of 1 TeV/c muons after traversing 3 m of iron, as obtained with Van Ginniken's TRAMU muon transport code [48].

10.10. Čerenkov and transition radiation [4,51,52]

A charged particle radiates if its velocity is greater than the local phase velocity of light (Čerenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy physics detectors.

Čerenkov Radiation. The half-angle θ_c of the Čerenkov cone for a particle with velocity βc in a medium with index of refraction n is

$$\theta_c = \arccos(1/n\beta)$$
$$\approx \sqrt{2(1-1/n\beta)} \quad \text{for small } \theta_c, \textit{e.g.} \text{ in gases.} \tag{10.29}$$

The threshold velocity β_t is $1/n$, and $\gamma_t = 1/(1-\beta_t^2)^{1/2}$. Therefore, $\beta_t\gamma_t = 1/(2\delta+\delta^2)^{1/2}$, where $\delta = n-1$. Values of δ for various commonly used gases are given as a function of pressure and wavelength in Ref. 53. For values at atmospheric pressure, see Table 6.1. Data for other commonly used materials are given in Ref. 54.

The number of photons produced per unit path length of a particle with charge ze and per unit energy interval of the photons is

$$\frac{d^2N}{dEdx} = \frac{\alpha z^2}{\hbar c}\sin^2\theta_c = \frac{\alpha^2 z^2}{r_e\, m_e c^2}\left(1-\frac{1}{\beta^2 n^2(E)}\right)$$
$$\approx 370\sin^2\theta_c(E)\ \text{eV}^{-1}\text{cm}^{-1} \qquad (z=1)\ , \tag{10.30}$$

or, equivalently,

$$\frac{d^2N}{dxd\lambda} = \frac{2\pi\alpha z^2}{\lambda^2}\left(1-\frac{1}{\beta^2 n^2(\lambda)}\right)\ . \tag{10.31}$$

The index of refraction is a function of photon energy E, as is the sensitivity of the transducer used to detect the light. For practical use, Eq. (10.30) must be multiplied by the the transducer response function and integrated over the region for which $\beta n(E) > 1$. Further details are given in the discussion of Čerenkov detectors in the Detectors section (Sec. 12 of this *Review*).

Transition Radiation. The energy radiated when a particle with charge ze crosses the boundary between vacuum and a medium with plasma frequency ω_p is

$$I = \alpha z^2\gamma\hbar\omega_p/3\ , \tag{10.32}$$

where

$$\hbar\omega_p = \sqrt{4\pi N_e r_e^3}\, m_e c^2/\alpha$$
$$= \sqrt{4\pi N_e a_\infty^3}\ 2\times 13.6\ \text{eV}\ . \tag{10.33}$$

Here N_e is the electron density in the medium, r_e is the classical electron radius, and a_∞ is the Bohr radius. For styrene and similar materials, $\sqrt{4\pi N_e a_\infty^3} \approx 0.8$, so that $\hbar\omega_p \approx 20$ eV. The typical emission angle is $1/\gamma$.

The radiation spectrum is logarithmically divergent at low energies and decreases rapidly for $\hbar\omega/\gamma\hbar\omega_p > 1$. About half the energy is emitted in the range $0.1 \le \hbar\omega/\gamma\hbar\omega_p \le 1$. For a particle with $\gamma = 10^3$, the radiated photons are in the soft x-ray range 2 to 20 eV. The γ dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a typical radiated photon energy of $\gamma\hbar\omega_p/4$, the quantum yield is

$$N_\gamma \approx \frac{1}{2}\,\frac{\alpha z^2\gamma\hbar\omega_p}{3}\Big/\frac{\gamma\hbar\omega_p}{4}$$
$$\approx \tfrac{2}{3}\alpha z^2 \approx 0.5\%\times z^2\ . \tag{10.34}$$

More precisely, the number of photons with energy $\hbar\omega > \hbar\omega_0$ is given by [55]

$$N_\gamma(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi}\left[\left(\ln\frac{\gamma\hbar\omega_p}{\hbar\omega_0}-1\right)^2+\frac{\pi^2}{12}\right]\ , \tag{10.35}$$

within corrections of order $(\hbar\omega_0/\gamma\hbar\omega_p)^2$. The number of photons above a fixed energy $\hbar\omega_0 << \gamma\hbar\omega_p$ thus grows as $(\ln\gamma)^2$, but the number above a fixed fraction of $\gamma\hbar\omega_p$ (as in the example above) is constant. For example, for $\hbar\omega > \gamma\hbar\omega_p/10$, $N_\gamma = 2.519\,\alpha z^2/\pi = 0.59\%\times z^2$.

The yield can be increased by using a stack of plastic foils with gaps between. However, interference can be important, and the soft x rays are readily absorbed in the foils. The first problem can be overcome by choosing thicknesses and spacings large compared to the "formation length" $D = \gamma c/\omega_p$, which in practical situations is tens of μm. Other practical problems are discussed in Sec. 12.

11. PHOTON AND ELECTRON ATTENUATION

Photon Attenuation Length

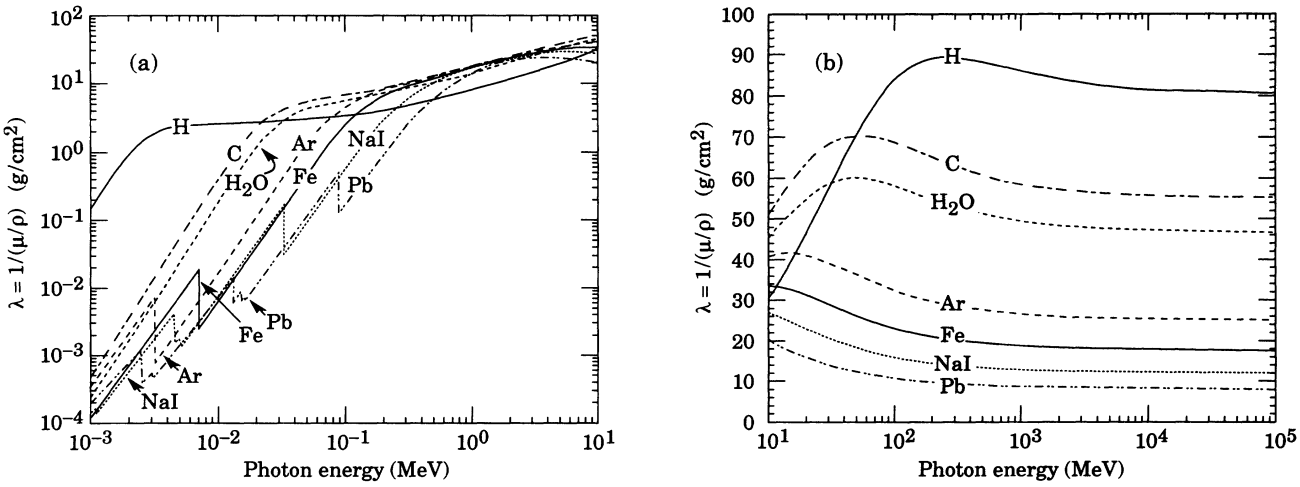

Figure 11.1: The photon mass attenuation length $\lambda = 1/(\mu/\rho)$ (also known as mfp, mean free path) for various absorbers as a function of photon energy, where μ is the mass attenuation coefficient. For a homogeneous medium of density ρ, the intensity I remaining after traversal of thickness t is given by the expression $I = I_0 \exp(-t\rho/\lambda)$. The accuracy is a few percent. Interpolation to other Z should be done in the cross section $\sigma = A/\lambda N_A$ cm^2/atom, where A is the atomic weight of the absorber material in grams and N_A is the Avogadro number. For a chemical compound or mixture, use $(1/\lambda)_{\rm eff} \approx \sum w_i(1/\lambda)_i$, accurate to a few percent, where w_i is the proportion by weight of the i^{th} constituent. The processes responsible for attenuation are given in Fig. 11.4. Not all of these processes necessarily result in detectable attenuation. For example, coherent Rayleigh scattering off an atom may occur at such low momentum transfer that the change in energy and momentum of the photon may not be significant.

(a) Low-energy region.

(b) The photon mass attenuation length, high-energy range (note that ordinate is linear scale). The attenuation length is constant beyond the range shown for at least two decades in energy.

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data **9**, 1023 (80). See also J.H. Hubbell, Int. J. of Applied Rad. and Isotopes **33**, 1269 (82). Data courtesy J.H. Hubbell.

Photon Pair Conversion Probability

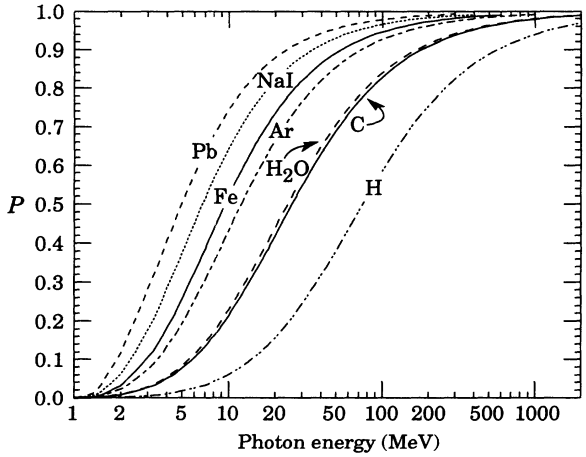

Figure 11.2: Probability P that a photon interaction will result in conversion to an e^+e^- pair. Except for a few-percent contribution from photonuclear absorption around 10 or 20 MeV, essentially all other interactions result in Compton scattering off an atomic electron. For a photon attenuation length λ (g/cm^2) (Fig. 11.1), the probability that a given photon will produce an electron pair (without first Compton scattering) in thickness t (cm) of absorber of density ρ (g/cm^3) is $P[1 - \exp(-t\rho/\lambda)]$.

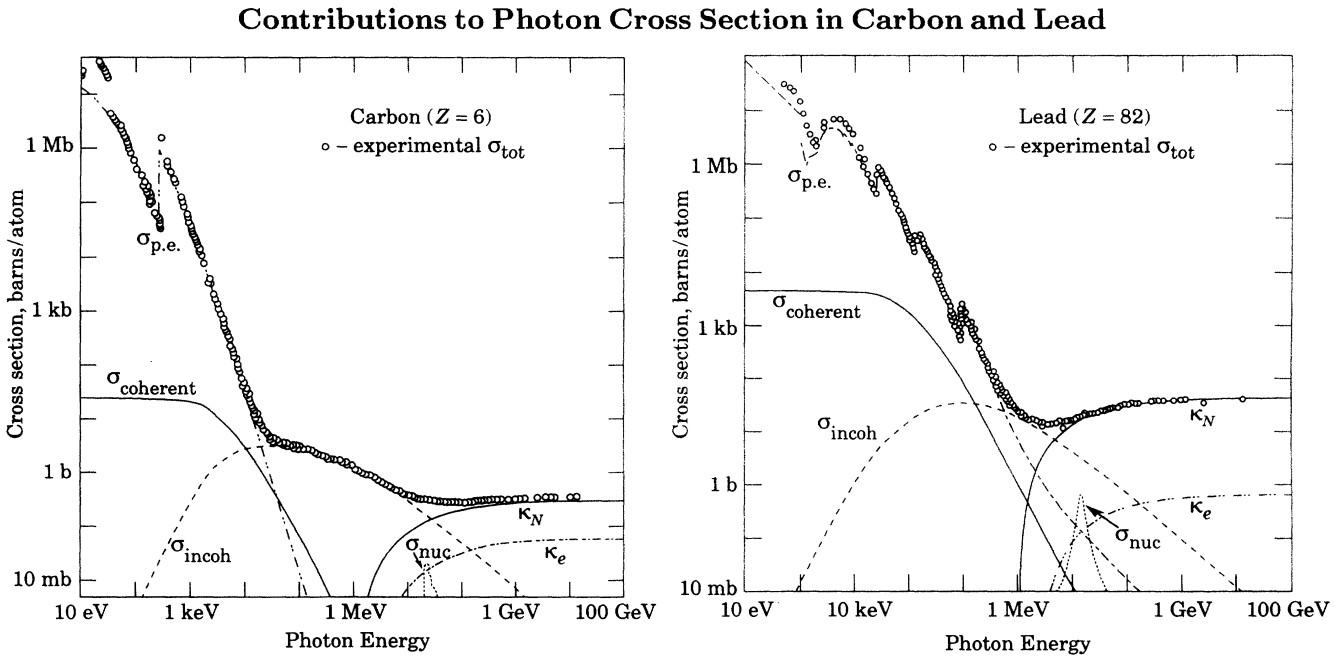

Figure 11.3: Photon total cross sections as a function of energy in carbon and lead, showing the contributions of different processes.

$\sigma_{\text{p.e.}}$ = Atomic photo-effect (electron ejection, photon absorption)
σ_{coherent} = Coherent scattering (Rayleigh scattering—atom neither ionized nor excited)
$\sigma_{\text{incoherent}}$ = Incoherent scattering (Compton scattering off an electron)
κ_n = Pair production, nuclear field
κ_e = Pair production, electron field
σ_{nuc} = Photonuclear absorption (nuclear absorption, usually followed by emission of a neutron or other particle)

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data **9**, 1023 (80). The photon total cross section is assumed approximately flat for at least two decades beyond the energy range shown. Figures courtesy J.H. Hubbell.

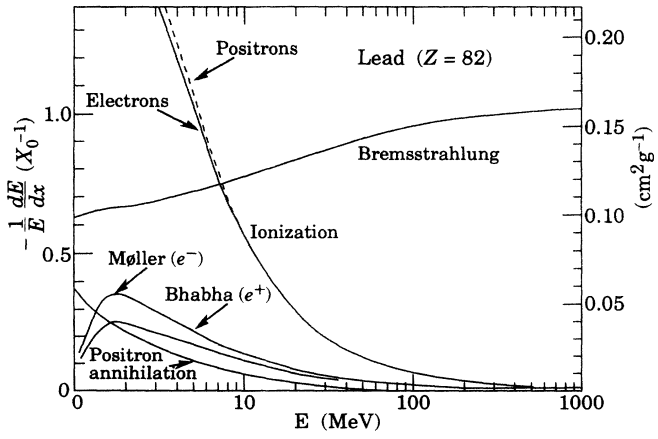

Figure 11.4: Fractional energy loss per radiation length in lead as a function of electron or positron energy. Electron (positron) scattering is considered as ionization when the energy loss per collision is below 0.255 MeV, and as Moller (Bhabha) scattering when it is above. Adapted from Fig. 3.2 from Messel and Crawford, *Electron-Photon Shower Distribution Function Tables for Lead, Copper, and Air Absorbers*, Pergamon Press, 1970. Messel and Crawford use X_0(Pb) = 5.82 g/cm^2, but we have modified the figures to reflect the value given in the Table of Atomic and Nuclear Properties of Materials, namely X_0(Pb) = 6.4 g/cm^2. The development of electron-photon cascades is approximately independent of absorber when the results are expressed in terms of inverse radiation lengths (*i.e.*, scale on left of plot).

12. PARTICLE DETECTORS

Updated 1992 by D.G. Coyne, R.W. Fast, R.D. Kephart, B. Mansoulie, H.F.W. Sadrozinski, H.G. Spieler, and C.L. Woody

In this section we give various parameters for common detector components. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. A more detailed discussion of detectors can be found in Ref. 1. In Table 12.1 are given typical spatial and temporal resolutions of common detectors.

Table 12.1: Typical detector characteristics.

Detector Type	Accuracy (rms)	Resolution Time	Dead Time
Bubble chamber	10 to 150 μm	1 ms	50 ms[a]
Streamer chamber	300 μm	2 μs	100 ms
Proportional chamber	$\geq$ 300 μm[b,c]	50 ns	200 ns
Drift chamber	50 to 300 μm	2 ns[d]	100 ns
Scintillator	—	150 ps	10 ns
Emulsion	1 μm	—	—
Silicon strip	$\frac{\text{pitch}}{3 \text{ to } 7}$ [e]	*f*	*f*
Silicon pixel	2 μm[g]	*f*	*f*

[a] Multiple pulsing time.

[b] 300 μm is for 1 mm pitch.

[c] Delay line cathode readout can give $\pm$150 μm parallel to anode wire.

[d] For two chambers.

[e] The highest resolution ("7") is obtained for small-pitch detectors ($\lesssim$ 25 μm) with pulse-height-weighted center finding.

[f] Limited at present by properties of the readout electronics. (Time resolution of $\leq$ 15 ns is planned for the SDC silicon tracker.)

[g] Analog readout of 34 μm pitch, monolithic pixel detectors.

12.1. Plastic scintillators

The photon yield in the frequency range of practical photomultiplier tubes is $\approx$ 1 photon per 100 eV of charged particle ionization energy loss in plastic scintillator [2]. One must take into account the light collection efficiency ($\lesssim$10% for typical 1-cm-thick scintillator), the attenuation length (1 to 4 m for typical scintillators [3]), and the quantum efficiency of the photomultiplier cathode ($\lesssim$25% when folded with a typical scintillator emission spectrum).

12.2. Inorganic scintillators

Table 12.2 gives a partial list of commonly-used inorganic scintillators in high-energy and nuclear physics [4–11]. These scintillating crystals are generally used where high density and good energy resolution are required. In a crystal which contains nearly all of the energy deposited by an incident particle, the energy resolution is determined largely, but not totally, by the light output. The table gives the light output of the various materials relative to NaI, which has an intrinsic light output of about 40000 photons per MeV of energy deposit. The detected signal is usually quoted in terms of photoelectrons per MeV produced by a given photodetector. The relationship between photons/MeV produced and p.e.'s/MeV detected involves factors for light collection efficiency (typically 10–50%, depending on geometry) and the quantum efficiency of the detector ($\sim$ 15–20% for photomultiplier tubes and $\sim$ 70% for silicon photodiodes for visible wavelengths). The quantum efficiency of the detector is usually highly wavelength dependent and should be matched to the particular crystal of interest to give the highest quantum yield at the wavelength corresponding to the peak of the scintillation emission. The comparison of the light output given in Table 12.2 is for a standard photomultiplier tube with a bialkali photocathode. For scintillators which emit in the UV, a detector with a quartz window should be used.

Table 12.2: Properties of several inorganic crystal scintillators.

	NaI(Tl)	BGO	BaF_2	CsI(Tl)	CsI(pure)
Density (g/cm^3)	3.67	7.13	4.89	4.53	4.53
Radiation length (cm)	2.59	1.12	2.05	1.85	1.85
Molière radius (cm)	4.5	2.4	3.4	3.8	3.8
dE/dx (MeV/cm) (per mip)	4.8	9.2	6.6	5.6	5.6
Nucl. int. length (cm)	41.4	22.0	29.9	36.5	36.5
Decay time (ns)	250	300	0.7[f]	1000	10, 36[f]
			620[s]		$\sim$ 1000[s]
Peak emission λ (nm)	410	480	220[f]	565	305[f]
			310[s]		$\sim$ 480[s]
Refractive index	1.85	2.20	1.56	1.80	1.80
Relative light output	1.00	0.15	0.05[f]	0.40	0.10[f]
			0.20[s]		0.02[s]
Hygroscopic	very	no	slightly	somewhat	somewhat

f = fast component, *s* = slow component

12.3. Čerenkov detectors

Čerenkov detectors utilize one or more of the properties of Čerenkov radiation discussed in the Passages of Particles through Matter section (Sec. 10 of this *Review*): the existence of a *threshold* for radiation; the dependence of the Čerenkov cone half-angle θ_c on the *velocity* of the particle; the dependence of the *number of emitted photons* on the particle's velocity. The presence of the refractive index n in the relations allows tuning these quantities for a particular experimental application (*e.g.*, using pressurized gas and/or various liquids as radiators).

The number of photoelectrons (p.e.'s) detected in a given device or channel is

$$N_{\text{p.e.}} = L\frac{\alpha^2 z^2}{r_e\, m_e c^2}\int \epsilon_{\text{coll}}(E)\,\epsilon_{\text{det}}(E)\sin^2\theta_c(E)dE\ , \qquad (12.1)$$

where L is the path length in the radiator, ϵ_{coll} is the efficiency for collecting the Čerenkov light, ϵ_{det} is the quantum efficiency of the transducer (photomultiplier or equivalent), and $\alpha^2/(r_e\, m_e c^2) = 370\ \text{cm}^{-1}\text{eV}^{-1}$. The quantities ϵ_{coll}, ϵ_{det}, and θ_c are all functions of the photon energy E, although in typical detectors θ_c (or, equivalently, the index of refraction) is nearly constant over the useful range of photocathode sensitivity. In this case,

$$N_{\text{p.e.}} \approx LN_0\left\langle\sin^2\theta_c\right\rangle \qquad (12.2)$$

with

$$N_0 = \frac{\alpha^2 z^2}{r_e\, m_e c^2}\int \epsilon_{\text{coll}}\,\epsilon_{\text{det}}dE\ . \qquad (12.3)$$

We take $z = 1$, the usual case in high-energy physics, in the following discussion.

Threshold Čerenkov detectors make a simple yes/no decision based on whether the particle is above/below the Čerenkov threshold velocity $\beta_t = 1/n$. Careful designs give $\langle\epsilon_{\text{coll}}\rangle \gtrsim 90\%$. For a photomultiplier with a typical bialkali cathode, $\int \epsilon_{\text{det}}dE \approx 0.27$, so that

$$N_{\text{p.e.}}/L \approx 90\ \text{cm}^{-1}\left\langle\sin^2\theta_c\right\rangle \quad (i.e.,\ N_0 = 90\ \text{cm}^{-1})\ . \qquad (12.4)$$

Suppose, for example, that n is chosen so that the threshold for species a is p_t; that is, at this momentum species a has velocity $\beta_a = 1/n$. A second, lighter, species b with the same momentum has velocity β_b, so $\cos\theta_c = \beta_a/\beta_b$, and

$$\frac{N_{\text{p.e.}}}{L} \approx 90\ \text{cm}^{-1}\,\frac{m_a^2 - m_b^2}{p_t^2 + m_a^2}\ . \qquad (12.5)$$

For K/π separation at $p = 1$ GeV/c, $N_{\text{p.e.}}/L \approx 16\ \text{cm}^{-1}$ for π's and (by design) 0 for K's.

For limited path lengths $N_{\rm p.e.}$ can be small, and some minimum number is required to trigger external electronics. The overall efficiency of the device is controlled by Poisson fluctuations, which can be especially critical for separation of species where one particle type is dominant [12].

A related class of detectors uses the number of observed photoelectrons (or the calibrated pulse height) to discriminate between species or to set probabilities for each particle species [13].

Differential Čerenkov detectors exploit the dependence of θ_c on β, using optical focusing and/or geometrical masking to select particles having velocities in a specified region. With careful design, a velocity resolution of $\sigma_\beta/\beta \approx 10^{-4}$–$10^{-5}$ can be obtained [12,14].

Ring-Imaging Čerenkov detectors use all three properties of Čerenkov radiation in both small-aperture and 4π geometries. They are principally used as hypothesis-testing rather than yes/no devices; that is, the probability of various identification possibilities is established from θ_c and $N_{\rm p.e.}$ for a particle of known momentum. In most cases the optics map the Čerenkov cone onto a circle at the photodetector, often with distortions which must be understood.

The 4π devices [15,16] typically have both liquid (C_6F_{14}, $n = 1.276$) and gas (C_5F_{12}, $n = 1.0017$) radiators, the light from the latter being focused by mirrors. They achieve 3 σ separation of $e/\pi/K/p$ over wide ranges, as shown in Table 12.3. Great attention to detail, especially with the minimization of UV-absorbing impurities, is required to get $\langle\epsilon_{\rm coll}\rangle \gtrsim 50\%$.

Table 12.3: Momentum range for 3σ separation in the SLD ring-imaging Čerenkov detector.

Particle pair	Mom. range for 3 σ separation
e/π	$p \lesssim 5$ GeV/c
π/K	$0.23 \lesssim p \lesssim 20$ GeV/c
K/p	$0.82 \lesssim p \lesssim 30$ GeV/c

The phototransducer is typically a TPC/wire-chamber combination sensitive to single photoelectrons and having charge division or pads. This construction permits three-dimensional reconstruction of photoelectron origins, which is important for transforming the Čerenkov cone into a ring. Single photoelectrons are generated by doping the TPC gas (for instance, ethane/methane in some proportion) with $\sim 0.05\%$ TMAE [tetrakis(dimethylamino)ethylene] [17], leading to photon absorption lengths along the Čerenkov cone of ~ 30 mm. The readout wires must be equipped with special structures (blinds or wire gates) to prevent photon feedback from avalanches generating cross-talk photoelectrons in the TPC. Drift-gas purity must be maintained to assure mean drift lengths of the order of meters without recombination (*i.e.*, lifetimes of $\gtrsim 100$ μs at typical drift velocities of $\gtrsim 4$ cm/μs). The net $\langle\epsilon_{\rm det}\rangle$'s reach 30%, with the limitation being the TMAE quantum efficiency.

Photon energy cutoffs are set by the TMAE ($E > 5.4$ eV), the UV transparency of fused silica glass ($E < 7.4$ eV), and the C_6F_{14} ($E < 7.1$ eV). With effort one gets $50 \leq N_0 \leq 100$ for complete rings using liquid or gas. This includes losses due to electrostatic shielding wires and window/mirror reflections, but not gross losses caused by total internal reflection or inadequate coverage by the TPC's.

Such numbers allow determination of ring radii to ~0.5% (liquid) and ~2% (gas), leading to the particle species separations quoted above. Since the separation efficiencies may have "holes" as a function of p, detailed calculations are necessary.

12.4. Transition radiation detectors (TRD's)

It is evident from the discussion in the Passages of Particles Through Matter section (Sec. 10 of this *Review*) that transition radiation (TR) only becomes useful for particle detectors when the Lorentz factor $\gamma \gtrsim 10^3$. In practice, TRD's are used to provide e/π separation when $p \gtrsim 1$ GeV/c. (The momentum is usually measured elsewhere in the detector.) Since a soft x ray is radiated with about 1% probability per boundary crossing, practical detectors use radiators with several hundred interfaces, *e.g.* foils of lithium or plastic in a gas. Absorption inside the radiator and interference effects between interfaces are important [18,19].

A practical detector is composed of several similar modules, each consisting of a radiator and an x-ray detector. The radiator is made of foils or fibers of a low-Z material (for low absorption) in a low-Z gas such as helium. The x-ray detector is usually a wire chamber operated with a xenon-rich mixture in order to obtain a high conversion efficiency. As transition radiation is emitted at small angles, the chamber usually detects the sum of the ionization of the particle and of converted TR photons. The discrimination between electrons and pions can be based on the charges measured in each set, or on more sophisticated methods using pulse-shape analysis. The TRD in the DØ experiment serves as an example [20,21].

The major factor in the performance of a TRD is its overall length. Very roughly, the pion rejection factor for a detector with 90% electron efficiency is $10\,(L/20$ cm), where L is the overall length of a radiator with foils. Radiators with fibers are easier to build, but generally provide a rejection factor which is at least a factor of two lower.

12.5. Silicon photodiodes and particle detectors

Silicon detectors are p-n junction diodes operated at reverse bias. This forms a sensitive region depleted of mobile charge and sets up an electric field that sweeps charge liberated by radiation to the electrodes. The thickness of the depleted region is

$$W = \sqrt{\frac{2\epsilon\,(V + V_{bi})}{ne}} = \sqrt{2\rho\epsilon(V + V_{bi})}\,, \tag{12.6}$$

where V = external bias voltage

V_{bi} = "built-in" voltage (≈ 0.8 V for resistivities typically used in detectors

n = doping concentration

e = electron charge

ϵ = dielectric constant = $11.9\,\epsilon_0 \approx 1$ pF/cm

ρ = resistivity (typically 1–10 kΩ cm)

μ = charge carrier mobility

= 1350 cm^2 V^{-1} s^{-1} for electrons (n-type material)

= 450 cm^2 V^{-1} s^{-1} for holes (p-type material)

or

$$W = 0.5\ \mu\text{m} \times \sqrt{\rho(V + V_{bi})} \quad \text{for } n\text{-type material,} \tag{12.7}$$

and

$$W = 0.3\ \mu\text{m} \times \sqrt{\rho(V + V_{bi})} \quad \text{for } p\text{-type material,} \tag{12.8}$$

where V is in volts and ρ is in Ω cm.

The corresponding capacitance per unit area is

$$C = \frac{\epsilon}{W} \approx 1\,[\text{pF/cm}]\,\frac{1}{W}\,. \tag{12.9}$$

In strip detectors the capacitance is dominated by the strip-to-strip fringing capacitance of $\sim$ 1–1.5 pF cm^{-1} of strip length at a strip pitch of 25–50 μm.

About 3.6 eV is required to create an electron-hole pair. For minimum-ionizing particles, the most probable charge deposition in a

300 μm thick silicon detector is about 4 fC (25000 electrons). Readily available photodiodes have quantum efficiences > 70% for wavelengths between 600 nm and 1 μm. UV extended photodiodes have useful efficiency down to 200 nm. In applications in which photodiodes detect light from scintillators, care must be taken so that signal from the scintillator is larger than that produced by particles going through the photodiode.

Collection time decreases with increased depletion voltage, and can be reduced further by operating the detector with "overbias," *i.e.*, a bias voltage exceeding the value required to fully deplete the device. The collection time is limited by velocity saturation at high fields; at an average field of 10^4 V/cm, the collection times is about 15 ps/μm for electrons and 30 ps/μm for holes. In typical strip detectors of 300 μm thickness, electrons are collected within about 8 ns, and holes within about 25 ns.

Position resolution is limited by transverse diffusion during charge collection (typically 5 μm for 300 μm thickness) and by knock-on electrons. Resolutions of 3–4 μm (rms) have been obtained in beam tests. In magnetic fields, the Lorentz drift can increase the spatial spread appreciably (see "Hall effect" in semiconductor textbooks).

Radiation damage occurs through two basic mechanisms:

1. Bulk damage due to displacement of atoms from their lattice sites. This leads to increased leakage current, carrier trapping, and changes in doping concentration. Displacement damage depends on the nonionizing energy loss, *i.e.*, particle type and energy. The dose should be specified as a fluence of particles of a specific type and energy.
2. Surface damage due to charge build-up in surface layers, which leads to increased surface leakage currents. In strip detectors the inter-strip isolation is affected. The effects of charge build-up are strongly dependent on the device structure and on fabrication details. Since the damage is determined directly by the absorbed energy, the dose should be specified in these units (rad or Gray).

The increase in leakage current due to bulk damage is $\Delta i = \alpha\phi$ per unit volume, where ϕ is the particle fluence and α the damage coefficient ($\alpha \approx 2 \times 10^{-17}$ A/cm for minimum ionizing protons and pions after long-term annealing; roughly the same value applies for 1 MeV neutrons). The doping concentration in n-type silicon changes as $n = n_0\exp(-\delta\phi) - \beta\phi$, where n_0 is the initial donor concentration, $\delta \approx 6 \times 10^{14}$ cm^2 determines donor removal, and $\beta \approx 0.03$ cm^{-1} describes acceptor creation. This leads to an initial increase in resisitivity until type-inversion changes the net doping from n to p. At this point the resistivity decreases, with a corresponding increase in depletion voltage. The safe operating limit of depletion voltage ultimately limits the detector lifetime. Strip detectors have remained functional at fluences beyond 10^{14} cm^{-2} for minimum ionizing protons. At this damage level, charge loss due to recombination and trapping also seems to become significant.

12.6. Proportional and drift chambers

Proportional chamber wire instability. The limit on the voltage V for a wire tension T, due to mechanical effects when the electrostatic repulsion of adjacent wires exceeds the restoring force of wire tension, is given by (SI units) [22]

$$V \leq \frac{s}{\ell C}\sqrt{4\pi\epsilon_0 T}\,, \tag{12.10}$$

where s, ℓ, and C are the wire spacing, length, and capacitance per unit length. An approximation to C for chamber half-gap t and wire diameter d (good for $s \lesssim t$) gives [23]

$$V \lesssim 59 T^{1/2}\left[\frac{t}{\ell} + \frac{s}{\pi\ell}\ln\left(\frac{s}{\pi d}\right)\right]\,, \tag{12.11}$$

where V is in kV, and T is in grams-weight equivalent.

Proportional and drift chamber potentials The potential distributions and fields in a proportional or drift chamber can usually be calculated with good accuracy from the exact formula for the potential around an array of parallel line charges q (coul/m) along z and located at $y = 0$, $x = 0, \pm s, \pm 2s, \ldots$,

$$V(x,y) = -\frac{q}{4\pi\,\epsilon_0}\ln\left\{4\left[\sin^2\left(\frac{\pi x}{s}\right) + \sinh^2\left(\frac{\pi y}{s}\right)\right]\right\}\,. \tag{12.12}$$

Errors from the presence of cathodes, mechanical defects, TPC-type edge effects, *etc.*, are usually small and are beyond the scope of this review.

12.7. Calorimeters

Electromagnetic calorimeters. The development of electromagnetic showers is discussed in the "Passage of Particles Through Matter" section (Sec. 10 of this *Review*). Formulae are given for the approximate description of average showers, but since the physics of electromagnetic showers is well understood, detailed and reliable Monte Carlo simulation is possible. EGS4 has emerged as the standard [24].

The resolution of sampling calorimeters (hadronic and electromagnetic) is usually dominated by sampling fluctuations, leading to fractional resolution σ/E scaling inversely as the square root of the incident energy. Homogenous calorimeters, such as solid NaI(Tl), will in general not have resolution varying as $1/\sqrt{E}$. At high energies deviations from $1/\sqrt{E}$ occur because of noise, pedestal fluctuations, nonuniformities, calibration errors, and incomplete shower containment. Such effects are usually included by adding a constant term to σ/E, either in quadrature or (incorrectly) directly. In the case of the hadronic cascades discussed below, noncompensation also contributes to the constant term.

In Table 12.4 we give resolution as measured in detectors using typical EM calorimeter technologies. In almost all cases the installed calorimeters yield worse resolution than test beam prototypes for a variety of practical reasons. Where possible actual detector performance is given. For a fixed number of radiation lengths, the FWHM in sandwich detectors would be expected to be proportional to $\sqrt{t}$ for t (= plate thickness) ≥ 0.2 radiation lengths [25].

Given sufficient transverse granularity early in the calorimeter, position resolution of the order of a millimeter can be obtained.

Table 12.4: Resolution of typical electromagnetic calorimeters. E is in GeV.

Detector	Resolution
NaI(Tl) (Crystal Ball [26]; 20 X_0)	$2.7\%/E^{1/4}$
Lead glass (OPAL [27])	$5\%/\sqrt{E}$
Lead-liquid argon (NA31 [28]; 80 cells: 27 X_0, 1.5 mm Pb + 0.6 mm Al + 0.8 mm G10 + 4 mm LA)	$7.5\%/\sqrt{E}$
Lead-scintillator sandwich (ARGUS [29], LAPP-LAL [30])	$9\%/\sqrt{E}$
Lead-scintillator spaghetti (CERN test module) [31]	$13\%/\sqrt{E}$
Proportional wire chamber (MAC; 32 cells: 13 X_0, 2.5 mm typemetal + 1.6 mm Al) [32]	$23\%/\sqrt{E}$

Hadronic calorimeters [33,34]. The length scale appropriate for hadronic cascades is the nuclear interaction length, given very roughly by

$$\lambda_I \approx 35\ \mathrm{g\ cm^{-2}} A^{1/3}\,. \tag{12.13}$$

Longitudinal energy deposition profiles are characterized by a sharp peak near the first interaction point (from the fairly local deposition of EM energy resulting from π^0's produced in the first interaction), followed by a more gradual development with a maximum at

$$x/\lambda_I \equiv t_{\max} \approx 0.2\ln(E/1\ \mathrm{GeV}) + 0.7 \tag{12.14}$$

as measured from the front of the detector.

The depth required for containment of a fixed fraction of the energy also increases logarithmically with incident particle energy. The thickness of iron required for 95% (99%) containment of cascades induced by single hadrons is shown in Fig. 12.1 [35]. Two of the sets of data are from large neutrino experiments, while the third is from a commonly used parametrization. Depths as measured in nuclear interaction lengths presumably scale to other materials. From the same data it can be concluded that the requirement that 95% of the energy in 95% of the showers be contained requires 40 to 50 cm (2.4 to 3.0 λ_I) more material material than for an average 95% containment.

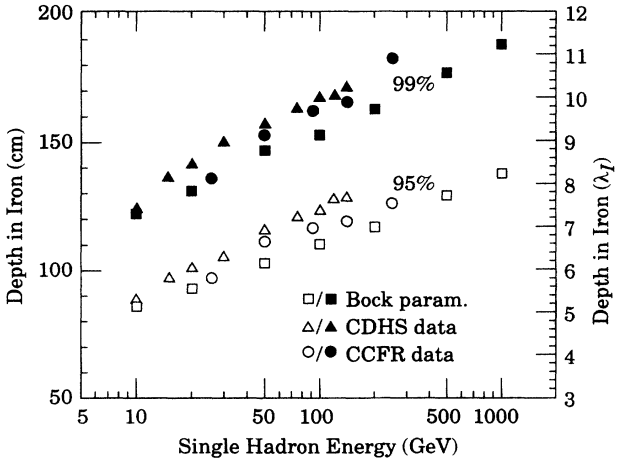

Figure 12.1: Required calorimeter thickness for 95% and 99% hadronic cascade containment in iron, on the basis of data from two large neutrino detectors and the parametrization of Bock *et al.* [35].

The transverse dimensions of hadronic showers also scale as λ_I, although most of the energy is contained in a narrow core.

The energy deposit in a hadronic cascade consists of a prompt EM component due to π^0 production and a slower component mainly due to low-energy hadronic activity. In general, these energy depositions are converted to electrical signals with different efficiencies [36]. The ratio of the conversion efficiencies is usually called the intrinsic e/h ratio. If $e/h = 1.0$ the calorimeter is said to be *compensating*. If it differs from unity by more than 5% or 10%, detector performance is compromised because of fluctuations in the π^0 content of the cascades. Problems include:

a) A skewed signal distribution;

b) A response ratio for electrons and hadrons (the "e/π ratio") which is different from unity and depends upon energy;

c) A nonlinear response to hadrons (the response per GeV is proportional to the reciprocal of e/π);

d) A constant contribution to detector resolution, almost proportional to the degree of noncompensation. The coefficient relating the constant term to $|1 - e/h|$ is 14% according to FLUKA simulations, and 21% according to Wigman's calculations [33].

In most cases e/h is greater than unity, particularly if little hydrogen is present or if the gate time is short. This is because much of the low-energy hadronic energy is "hidden" in nuclear binding energy release, low-energy spallation products, *etc.* Partial correction for these losses occurs in a sampling calorimeter with thick plates, because a disproportionate fraction of electromagnetic energy is deposited in the inactive region. For this reason, it is very unlikely that a fully sensitive detector such as BGO or glass can be made compensating.

Compensation has been demonstrated in calorimeters with 2.5 mm scintillator sheets sandwiched between 3 mm depleted uranium plates [38] or 10 mm lead plates [39]; resolutions σ/E of $0.34/\sqrt{E}$ and $0.44/\sqrt{E}$ were obtained for these cases (E in GeV). The former was shown to be linear to within 2% over three orders of magnitude in energy, with approximately Gaussian signal distributions.

dE/dx resolution in argon. Particle identification by dE/dx is dependent on the width of the distribution. For relativistic incident particles with charge e in a multiple-sample Ar gas counter with no lead [40],

$$\left.\frac{dE}{dx}\right|_{\rm FWHM} \Big/ \left.\frac{dE}{dx}\right|_{\rm most\ probable} = 0.96\, N^{-0.46}\,(xp)^{-0.32}\ , \qquad (12.15)$$

where N = number of samples, x = thickness per sample (cm), p = pressure (atm.). Most commonly used chamber gases (except Xe) give approximately the same resolution.

Free electron drift velocities in liquid ionization chambers [41–44]. Velocity as a function of electric field strength is given in Fig. 12.2.

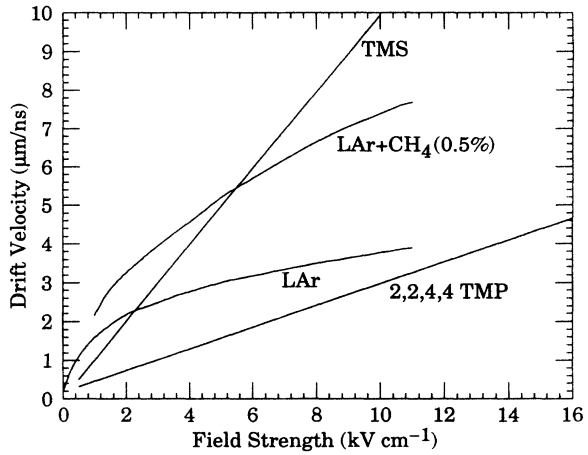

Figure 12.2: Electron drift velocity as a function of field strength for commonly used liquids.

12.8. Measurement of particle momenta in a uniform magnetic field [45]

The trajectory of a particle with momentum p (in GeV/c) and charge ze in a constant magnetic field $\vec{B}$ is a helix, with radius of curvature R and pitch angle λ. The radius of curvature and momentum component perpendicular to $\vec{B}$ are related by

$$p\cos\lambda = 0.3\, z\, B\, R\ , \qquad (12.16)$$

where B is in tesla and R is in meters.

The distribution of measurements of the curvature $k \equiv 1/R$ is approximately Gaussian. The curvature error for a large number of uniformly spaced measurements on the trajectory of a charged particle in a uniform magnetic field can be approximated by

$$(\delta k)^2 = (\delta k_{\rm res})^2 + (\delta k_{\rm ms})^2\ , \qquad (12.17)$$

where δk = curvature error

$\delta k_{\rm res}$ = curvature error due to finite measurement resolution

$\delta k_{\rm ms}$ = curvature error due to multiple scattering.

If many (≥ 10) uniformly spaced position measurements are made along a trajectory in a uniform medium,

$$\delta k_{\rm res} = \frac{\epsilon}{L'^2}\sqrt{\frac{720}{N+4}}\ , \qquad (12.18)$$

where N = number of points measured along track

L' = the projected length of the track onto the bending plane

ϵ = measurement error for each point, perpendicular to the trajectory.

If a vertex constraint is applied at the origin of the track, the coefficient under the radical becomes 320.

The contribution due to multiple Coulomb scattering is approximately

$$\delta k_{\rm ms} \approx \frac{(0.016)({\rm GeV}/c)z}{Lp\beta\cos^2\lambda}\sqrt{\frac{L}{X_0}}\,, \tag{12.19}$$

where p = momentum (GeV/c)

z = charge of incident particle in units of e

L = the total track length

X_0 = radiation length of the scattering medium (in units of length; the X_0 defined elsewhere must be multiplied by density)

β = the kinematic variable v/c.

More accurate approximations for multiple scattering may be found in the section on Passage of Particles Through Matter (Sec. 10 of this *Review*). The contribution to the curvature error is given approximately by $\delta k_{\rm ms} \approx 8 s^{\rm rms}_{\rm plane}/L^2$, where $s^{\rm rms}_{\rm plane}$ is defined there.

12.9. Superconducting solenoids for collider detectors

12.9.1. ***Basic (approximate) equations***: In all cases SI units are assumed, so that B is in tesla, E is in joules, dimensions are in meters, and $\mu_0 = 4\pi \times 10^{-7}$.

Magnetic field. The magnetic field at the center of a solenoid of length L and radius R, having N total turns and a current I is

$$B(0,0) = \frac{\mu_0 NI}{\sqrt{L^2+4R^2}}\,. \tag{12.20}$$

Stored energy. The energy stored in the magnetic field of any magnet is calculated by integrating B^2 over all space:

$$E = \frac{1}{2\mu_0}\int B^2 dV\,. \tag{12.21}$$

For a solenoid with an iron flux return in which the magnetic field is $< 2T$, the field in the aperture is approximately uniform and equal to $\mu_0 NI/L$. If the thickness of the coil is small, (which is the case if it is superconducting), then

$$E \approx (\pi/2\mu_0)B^2R^2L\,. \tag{12.22}$$

Cost of a superconducting solenoid [46]:

$$\text{Cost (in M\$)} = 0.523\,[(E/(1\ \text{MJ})]^{0.662} \tag{12.23}$$

Magnetostatic computer programs. It is too difficult to solve the Biot-Savart equation for a magnetic circuit which includes iron components and so iterative computer programs are used. These include POISSON, TOSCA [47], and ANSYS [48].

12.9.2. ***Scaling laws for thin solenoids***: For a detector in which the calorimetry is outside the aperture of the solenoid, the coil must be thin in terms of radiation and absorption lengths. This usually means that the coil is superconducting and that the vacuum vessel encasing it is of minimum real thickness and fabricated of a material with long radiation length. There are two major contributers to the thickness of a thin solenoid:

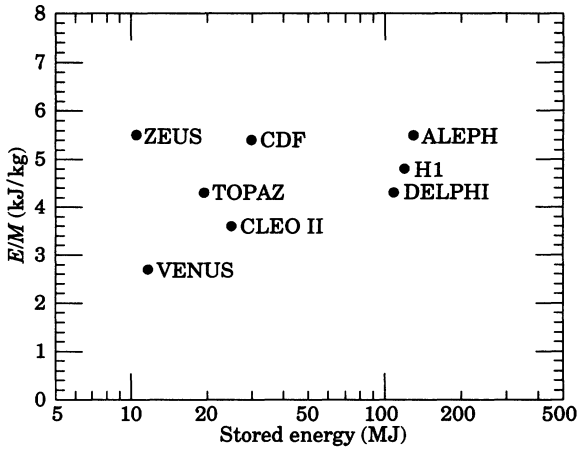

Figure 12.3: Ratio of stored energy to cold mass for existing thin detector solenoids.

1. The conductor, consisting of the current-carrying superconducting material (usually Cu/Nb-Ti) and the quench protecting stabilizer (usually aluminum), is wound on the inside of a structural support cylinder (usually aluminum also). This package typically represents about 60% of the total thickness in radiation lengths. The thickness scales approximately as B^2R.
2. Approximately another 25% of the thickness of the magnet comes from the outer cylindrical shell of the vacuum vessel. Since this shell is susceptible to buckling collapse, its thickness is determined by the diameter, length, and the modulus of the material of which it is fabricated. When designing this shell to a typical standard, the real thickness is

$$t = P_c D^{2.5}[(L/D) - 0.45(t/D)^{0.5}]/2.6Y^{0.4}\,, \tag{12.24}$$

where t = shell thickness (in), D = shell diameter (in), L = shell length (in), Y = modulus of elasticity (psi), and P_c = design collapse pressure (= 30 psi). For most large-diameter detector solenoids, the thickness to within a few percent is given by [49]

$$t = P_c D^{2.5}(L/D)/2.6Y^{0.4}\,. \tag{12.25}$$

12.9.3. ***Properties of collider detector solenoids***: The physical dimensions, central field, stored energy and thickness in radiation lengths normal to the beam line of the superconducting solenoids associated with the major colliders are given in Table 12.5.

Table 12.5: Properties of superconducting collider detector solenoids.

Experiment–Lab	Field (T)	Bore Dia (m)	Length (m)	Energy (MJ)	Thickness (X_0)
CDF-Fermilab	1.5	2.86	5.07	30	0.86
Topaz–KEK	1.2	2.72	5.4	19.5	0.70
Venus–KEK	0.75	3.4	5.64	12	0.52
Cleo II–Cornell	1.5	2.9	3.8	25	2.5
Aleph–CERN	1.5	5.0	7.0	130	1.7
Delphi–CERN	1.2	5.2	7.4	109	4.0
H1–DESY	1.2	5.2	5.75	120	1.2
Zeus–DESY	1.8	1.72	2.85	10.5	0.9

The ratio of stored energy to cold mass (E/M) is a useful performance measure. One would like the cold mass to be as small as possible to minimize the thickness, but temperature rise during a quench must also be minimized. Ratios as large as 8 kJ/kg may be possible (final temperature of 80 K after a fast quench with homogenous energy dump), but some contingency is desirable. This quantity is shown as a function of total stored energy for some major collider detectors in Fig. 12.3.

12.10. Radiation levels in detectors at hadron colliders

An SSC Central Design Group task force made a study of radiation levels to be expected in SSC detectors [50]. Its model assumed

- The machine luminosity at $\sqrt{s} = 40$ TeV is $\mathscr{L} = 10^{33}$ cm^{-2}s^{-1}, and the pp inelastic cross section is $\sigma_{\rm inel} = 100$ mb. This luminosity is effectively achieved for 10^7 s yr^{-1}. The interaction rate is thus 10^8 s^{-1}, or 10^{15} yr^{-1};
- All radiation comes from pp collisions at the interaction point;
- The charged particle distribution is (a) flat in pseudorapidity for $|\eta| < 6$ and (b) has a momentum distribution whose perpendicular component is independent of rapidity, which is taken as independent of pseudorapidity:

$$\frac{d^2N_{\rm ch}}{d\eta dp_\perp} = H\, f(p_\perp) \qquad (12.26)$$

(where $p_\perp = p\sin\theta$). Integrals involving $f(p_\perp)$ are simplified by replacing $f(p_\perp)$ by $\delta(p_\perp - \langle p_\perp\rangle)$; in the worst case this approximation introduces an error of less than 10%;
- Gamma rays from π^0 decay are as abundant as charged particles. They have approximately the same η distribution, but half the mean momentum;
- At the SSC ($\sqrt{s} = 40$ TeV), $H \approx 7.5$ and $\langle p_\perp\rangle \approx 0.6$ GeV/c; assumed values at other energies are given in Table 12.7. Together with the model discussed above, these values are thought to describe particle production to within a factor of two or better.

It then follows that the flux of charged particles from the interaction point passing through a normal area da located a distance $r_\perp$ from the beam line is given by

$$\frac{dN_{\rm ch}}{da} = \frac{1.2\times10^8\ {\rm s}^{-1}}{r_\perp^2}\ . \qquad (12.27)$$

In a typical organic material, a relativistic charged particle flux of 3×10^9 cm^{-2} produces an ionizing radiation dose of 1 Gy, where 1 Gy $\equiv$ 1 joule kg^{-1} (= 100 rads). The above result may thus be rewritten as dose rate,

$$\dot{D} = \frac{0.4\ {\rm MGy\ yr}^{-1}}{(r_\perp/1\ {\rm cm})^2}\ . \qquad (12.28)$$

If a magnetic field is present, "loopers" may increase this dose rate by a factor of two.

In a medium in which cascades can develop, the ionizing dose or neutron fluence is proportional to $dN_{\rm ch}/da$ multiplied by $\langle E\rangle^\alpha$, where $\langle E\rangle$ is the mean energy of the particles going through da and the power α is slightly less than unity. Since $E \approx p = p_\perp/\sin\theta$ and $r_\perp = r\sin\theta$, the above expression for $dN_{\rm ch}/da$ becomes

$$\text{Dose or fluence}^* = \frac{A}{r^2}\cosh^{2+\alpha}\eta = \frac{A}{r^2\sin^{2+\alpha}\theta}\ . \qquad (12.29)$$

The constant A contains the total number of interactions $\sigma_{\rm inel}\int\mathscr{L}dt$, so the ionizing dose or neutron fluence at another accelerator scales as $\sigma_{\rm inel}\int\mathscr{L}dt\,H\,\langle p_\perp\rangle^\alpha$.

The dose or fluence in a calorimeter scales as $1/r^2$, as does the neutron fluence inside a central cavity with characteristic dimension r.

Under all conditions so far studied, the neutron spectrum shows a broad log-normal distribution peaking at just under 1 MeV. In a 2 m radius central cavity of a detector with coverage down to $|\eta| = 3$, the average neutron flux is 2×10^{12} cm^{-2}yr^{-1}, including secondary scattering contributions.

Values of A and α are given in Table 12.6 for several relevant situations. Examples of scaling to other accelerators are given in Table 12.7. It should be noted that the assumption that all radiation comes from the interaction point does not apply to the present generation of accelerators.

Table 12.6: Coefficients $A/(100\ {\rm cm})^2$ and α for the evaluation of calorimeter radiation levels at cascade maxima under SSC nominal operating conditions. At a distance r and angle θ from the interaction point the annual fluence or dose is $A/(r^2\sin^{2+\alpha}\theta)$.

Quantity	$A/(100\ {\rm cm})^2$	Units	$\langle p_\perp\rangle$	α
Neutron flux	1.5×10^{12}	cm^{-2}yr^{-1}	0.6 GeV/c	0.67
Dose rate from photons	124	Gy yr^{-1}	0.3 GeV/c	0.93
Dose rate from hadrons	29	Gy yr^{-1}	0.6 GeV/c	0.89

Table 12.7: A rough comparison of beam-collision induced radiation levels at the Tevatron, UNK, high-luminosity LHC, and SSC.

	Tevatron	UNK-3	LHC	SSC
$\sqrt{s}$ (TeV)	1.8	6	16	40
$\mathscr{L}_{\rm nom}$ (cm^{-2}s^{-1})	2×10^{30}	4×10^{32}	4×10^{34}[a]	1×10^{33}
$\sigma_{\rm inel}$	59 mb	80 mb	86 mb	100 mb
H	4.1	4.5	6.3	7.5
$\langle p_\perp\rangle$ (GeV/c)	0.46	0.52	0.55	0.60
Relative dose rate[b]	5×10^{-4}	0.2	27	1

[a] High-luminosity option.

[b] Proportional to $\mathscr{L}_{\rm nom}\,\sigma_{\rm inel}\,H\,\langle p_\perp\rangle^{0.7}$

The constant A includes factors evaluated with cascade simulation programs as well as constants describing particle production at the interaction point. It is felt that each could introduce an error as large as a factor of two in the results.

13. RADIOACTIVITY & RADIATION PROTECTION

Revised Sept. 1991 with assistance from N.A. Greenhouse.

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

• **Unit of activity** = becquerel (curie):

1 Bq = 1 disintegration s^{-1} [= $1/(3.7 \times 10^{10})$ Ci]

• **Unit of absorbed dose** = gray (rad):

1 Gy = 1 joule kg^{-1} (= 10^4 erg g^{-1} = 100 rad)

= 6.24×10^{12} MeV kg^{-1} deposited energy

• **Unit of exposure**, the quantity of x- or γ- radiation at a point in space integrated over time, in terms of charge of either sign produced by showering electrons in a small volume of air about the point:

= 1 coul kg^{-1} of air (roentgen; 1 $R = 2.58 \times 10^{-4}$ coul kg^{-1})

= 1 esu cm^{-3}(= 87.8 erg released energy per g of air)

Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving. This unit is somewhat historical, but appears on many measuring instruments.

• **Unit of equivalent dose** (for biological damage) = sievert [= 100 rem (**r**oentgen **e**quivalent for **m**an)]: Equivalent dose in Sv = absorbed dose in grays $\times$ w_R, where w_R (radiation weighting factor, formerly the quality factor Q) expresses long-term risk (primarily cancer and leukemia) from low-level chronic exposure. It depends upon the type of radiation and other factors, as follows [1]:

Table 13.1: Radiation weighting factors.

Radiation	w_R
X- and γ-rays, all energies	1
Electrons and muons, all energies	1
Neutrons < 10 keV	5
10–100 keV	10
> 100 keV to 2 MeV	20
2–20 MeV	10
> 20 MeV	5
Protons (other than recoils) > 2 MeV	5
Alphas, fission fragments, & heavy nuclei	20

• **Natural annual background**, all sources: Most world areas, whole-body equivalent dose rate $\approx$ (0.4–4) mSv (40–400 millirems). Can range up to 50 mSv (5 rems) in certain areas. U.S. average $\approx$ 3.6 mSv, including $\approx$ 2 mSv ($\approx$ 200 mrem) from inhaled natural radioactivity, mostly radon and radon daughters (0.1–0.2 mSv in open areas. Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines).

• **Cosmic ray background** in counters (Earth's surface): $\sim$ 1 min^{-1} cm^{-2} sr. For more accurate estimates and details, see the Cosmic Rays section (Sec. 14 of this *Review*.

• **Fluxes** (per cm^2) to deposit one Gy, assuming uniform irradiation:

$\approx$ (**charged particles**) $6.24 \times 10^9/(dE/dx)$, where dE/dx (MeV g^{-1} cm^2), the energy loss per unit length, may be obtained from the Mean Range and Energy Loss figures.

$\approx 3.5 \times 10^9$ cm^{-2} minimum-ionizing singly-charged particles in carbon.

$\approx$ (**photons**) $6.24 \times 10^9/[Ef/\lambda]$, for photons of energy E (MeV), attenuation length λ (g cm^{-2}) (see Photon Attenuation Length figure), and fraction $f \lesssim 1$ expressing the fraction of the photon's energy deposited in a small volume of thickness $\ll \lambda$ but large enough to contain the secondary electrons.

$\approx 2 \times 10^{11}$ photons cm^{-2} for 1 MeV photons on carbon ($f \approx 1/2$).

(Quoted fluxes are good to about a factor of 2 for all materials.)

• **Recommended limits to exposure (whole-body dose):***

CERN: 15 mSv yr^{-1}

U.K.: 15 mSv yr^{-1}

U.S.: 50 mSv yr^{-1} (5 rem yr^{-1})†

• **Lethal dose**: Whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) 2.5–3.0 Gy (250–300 rads), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

For a recent review, see E. Pochin, *Nuclear Radiation: Risks and Benefits* (Clarendon Press, Oxford, 1983).

* The ICRP recomendation [1] is 20 mSv yr^{-1} averaged over 5 years, with the dose in any one year $\leq$ 50 mSv.

† Many laboratories in the U.S. and elsewhere set lower limits.

14. COSMIC RAY FLUXES

The fluxes of particles of different types depend at the $\sim 10\%$ level on the latitude, their energy, and the conditions of measurement. Some typical sea-level values [1] for charged particles are given below:

I_v flux per unit solid angle per unit horizontal area about vertical direction

$\equiv j(\theta = 0, \phi)$[$\theta$ = zenith angle, ϕ = azimuthal angle] ;

J_1 total flux crossing unit horizontal area from above

$$\equiv \int_{\theta \leq \pi/2} j(\theta, \phi)\ \cos\theta\ d\Omega\ [d\Omega = \sin\theta\ d\theta\ d\phi] ;$$

J_2 total flux from above (impinging on a sphere of unit cross-sectional area)

$$\equiv \int_{\theta \leq \pi/2} j(\theta, \phi)\ d\Omega\ .$$

	Total Intensity	Hard Component	Soft Component
I_v	1.1×10^2	0.8×10^2	0.3×10^2 m^{-2} s^{-1} sterad^{-1}
J_1	1.8×10^2	1.3×10^2	0.5×10^2 m^{-2} s^{-1}
J_2	2.4×10^2	1.7×10^2	0.7×10^2 m^{-2} s^{-1}

Very approximately, about 75% of all particles at sea level are penetrating, and are muons (the dominant portion of the hard component at sea level). The sea-level vertical flux ratio for protons to muons (both charges together) is about 3.5% at 1 GeV/c, decreasing to about 0.5% at 10 GeV/c.

The muon flux at sea level has a mean energy of 2 GeV and a differential spectrum falling as E^{-2}, steepening smoothly to $E^{-3.6}$ above a few TeV. The angular distribution is $\cos^2\theta$, changing to secθ at energies above a TeV, where θ is the zenith angle at production. The $\pm$ charge ratio is 1.25–1.30. The mean energy of muons originating in the atmosphere is roughly 300 GeV at slant depths $\gtrsim$ a few hundred meters. Beyond slant depths of $\sim$ 10 km water-equivalent, the muons are due primarily to in-the-earth neutrino interactions (roughly 1/8 interaction ton^{-1} year^{-1} for $E_\nu > 300$ MeV, $\sim$ constant throughout the earth) [2]. Muons from this source arrive with a mean energy of 20 GeV, and have a flux of 2×10^{-9} m^{-2} s^{-1} sterad^{-1} in the vertical direction and about twice that in the horizontal [3], down at least as far as the deepest mines.

"Emission probability" is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and e^- means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV e^+e^- annihilation photons depends upon the number of stopped positrons. Endpoint $\beta^\pm$ energies are listed. In some cases when energies are closely spaced, the γ-ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities are from E. Browne and R.B. Firestone, *Table of Radioactive Isotopes* (John Wiley & Sons, New York, 1986), recent *Nuclear Data Sheets*, and *X-ray and Gamma-ray Standards for Detector Calibration*, IAEA-TECDOC-619 (1991).

Neutron data are from *Neutron Sources for Basic Physics and Applications* (Pergamon Press, 1983).

16. PROBABILITY

Revised June 1994.

16.1. General [1–5]

Let x be a possible outcome of an observation. The probability of x is the relative frequency with which that outcome occurs out of a (possibly hypothetical) large set of similar observations. If x can take any value from a *continuous* range, we write $f(x;\theta)\,dx$ as the probability of observing x between x and $x+dx$. The function $f(x;\theta)$ is the *probability density function* (p.d.f.) for the *random variable* x, which may depend upon one or more parameters θ. If x can take on only *discrete* values (*e.g.*, the non-negative integers), then $f(x;\theta)$ is itself a probability, but we shall still call it a p.d.f. The p.d.f. is always normalized to unit area (unit sum, if discrete). Both x and θ may have multiple components and are then often written as column vectors. If θ is unknown and we wish to estimate its value from a given set of data measuring x, we may use statistics (see Sec. 17).

The *cumulative distribution function* $F(a)$ is the probability that $x \le a$:

$$F(a) = \int_{-\infty}^{a} f(x)\,dx \ . \tag{16.1}$$

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is expressly included in the integral or sum. Then $0 \le F(x) \le 1$, $F(x)$ is nondecreasing, and $\mathrm{Prob}(a < x \le b) = F(b) - F(a)$. If x is discrete, $F(x)$ is flat except at allowed values of x, where it has discontinuous jumps equal to $f(x)$.

Any function of random variables is itself a random variable, with (in general) a different p.d.f. The *expectation value* of any function $u(x)$ is

$$E\left[u(x)\right] = \int_{-\infty}^{\infty} u(x)\,f(x)\,dx \ , \tag{16.2}$$

assuming the integral is finite. For $u(x)$ and $v(x)$ any two functions of x, $E(u+v) = E(u) + E(v)$. For c and k constants, $E(cu+k) = cE(u) + k$.

The nth moment of a distribution is

$$\alpha_n \equiv E(x^n) = \int_{-\infty}^{\infty} x^n f(x) dx \ , \tag{16.3a}$$

and the nth moment about the mean of x, α_1, is

$$m_n \equiv E[(x-\alpha_1)^n] = \int_{-\infty}^{\infty} (x-\alpha_1)^n f(x) dx \ . \tag{16.3b}$$

The most commonly used moments are the mean μ and variance σ^2:

$$\mu \equiv \alpha_1 \tag{16.4a}$$

$$\sigma^2 \equiv \mathrm{Var}(x) \equiv m_2 = \alpha_2 - \mu^2 \ . \tag{16.4b}$$

The mean is the location of the "center of mass" of the probability density function, and the variance is a measure of the square of its width. Note that $\mathrm{Var}(cx+k) = c^2\mathrm{Var}(x)$.

Any odd moment about the mean is a measure of the skewness of the p.d.f. The simplest of these is the dimensionless coefficient of skewness $\gamma_1 \equiv m_3/\sigma^3$.

Besides the mean, another useful indicator of the "middle" of the probability distribution is the *median* x_{med}, defined by $F(x_{\mathrm{med}}) = 1/2$; *i.e.*, half the probability lies above and half lies below x_{med}. For a given *sample* of events, x_{med} is the value such that half the events have larger x and half have smaller x (not counting any that have the same x as the median). If the sample median lies between two observed x values, it is set by convention halfway between them. If the p.d.f. for x has the form $f(x-\mu)$ and μ is both mean and median, then for a large number of events N, the variance of the median approaches $1/[4Nf^2(0)]$, provided $f(0) > 0$.

Let x and y be two random variables with a joint p.d.f. $f(x,y)$. The *marginal* p.d.f. of x (the distribution of x with y unobserved) is

$$f_1(x) = \int_{-\infty}^{\infty} f(x,y)\,dy \ , \tag{16.5}$$

and similarly for the marginal p.d.f. $f_2(y)$. We define the *conditional* p.d.f. of x, given fixed y, by

$$f_3(y|x)\,f_1(x) = f(x,y) \ . \tag{16.6a}$$

Similarly, the conditional p.d.f. of y, given fixed x, is

$$f_4(x|y)\,f_2(y) = f(x,y) \ . \tag{16.6b}$$

From these definitions we immediately obtain Bayes' theorem [2]:

$$f_4(x|y) = \frac{f_3(y|x)\,f_1(x)}{f_2(y)} = \frac{f_3(y|x)\,f_1(x)}{\int f_3(y|x)\,f_1(x)\,dx} \ . \tag{16.7}$$

The mean of x is

$$\mu_x = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} x\,f(x,y)\,dx\,dy = \int_{-\infty}^{\infty} x\,f_1(x)\,dx \ , \tag{16.8}$$

and similarly for y. The *correlation* between x and y is a measure of the dependence of one on the other:

$$\rho_{xy} = E\left[(x-\mu_x)(y-\mu_y)\right]/\sigma_x\,\sigma_y = \mathrm{Cov}(x,y)/\sigma_x\,\sigma_y \ , \tag{16.9}$$

where σ_x and σ_y are defined in analogy with Eq. (16.4*b*). It can be shown that $-1 \le \rho_{xy} \le 1$. Here "Cov" is the covariance of x and y, a 2-dimensional analogue of the variance.

Two random variables are *independent* if and only if

$$f(x,y) = f_1(x)\,f_2(y) \ . \tag{16.10}$$

If x and y are independent then $\rho_{xy} = 0$; the converse is not necessarily true except for Gaussian-distributed x and y. If x and y are independent, $E[u(x)\,v(y)] = E[u(x)]\,E[v(y)]$, and $\mathrm{Var}(x+y) = \mathrm{Var}(x)+\mathrm{Var}(y)$; otherwise, $\mathrm{Var}(x+y) = \mathrm{Var}(x)+\mathrm{Var}(y)+2\mathrm{Cov}(x,y)$, and $E(u\,v)$ does not factor.

In a *change of continuous random variables* from $\boldsymbol{x} \equiv (x_1,\ldots,x_n)$, with p.d.f. $f(\boldsymbol{x}) = f(x_1,\ldots,x_n)$, to $\boldsymbol{y} \equiv (y_1,\ldots,y_n)$, a one-to-one function of the x_i's, the p.d.f. $g(\boldsymbol{y}) = g(y_1,\ldots,y_n)$ is found by substitution for $(x_1,\ldots,x_n)$ in f followed by multiplication by the absolute value of the Jacobian of the transformation; that is,

$$g(\boldsymbol{y}) = f\left[w_1(\boldsymbol{y}),\ldots,w_n(\boldsymbol{y})\right]|J| \ . \tag{16.11}$$

The functions w_i express the *inverse* transformation, $x_i = w_i(\boldsymbol{y})$ for $i = 1,\ldots,n$, and $|J|$ is the absolute value of the determinant of the square matrix $J_{ij} = \partial x_i/\partial y_j$. If the transformation from $\boldsymbol{x}$ to $\boldsymbol{y}$ is not one-to-one, the situation is more complex and a unique solution may not exist. For example, if the change is to $m < n$ variables, then a given y may correspond to more than one x, leading to multiple integrals over the contributions [1].

To change variables for discrete random variables simply substitute; no Jacobian is necessary because now f is a probability rather than a probability density.

If f depends upon a parameter set $\boldsymbol{\theta}$, a change to a different parameter set $\phi_i = \phi_i(\boldsymbol{\theta})$ is made by simple substitution; no Jacobian is used.

16.2. Characteristic functions

The characteristic function $\phi(u)$ associated with the p.d.f. $f(x)$ is essentially its (inverse) Fourier transform, or the expectation value of $\exp(iux)$:

$$\phi(u) = E(e^{iux}) = \int_{-\infty}^{\infty} e^{iux} f(x)dx \ . \tag{16.12}$$

It is often useful, and several of its properties follow [1].

It follows from Eqs. (16.3*a*) and (16.12) that the nth moment of the distribution $f(x)$ is given by

$$i^{-n} \frac{d^n \phi}{du^n}\bigg|_{u=0} = \int_{-\infty}^{\infty} x^n f(x)dx = \alpha_n \ . \tag{16.13}$$

Thus it is often easy to calculate all the moments of a distribution defined by $\phi(u)$, even when $f(x)$ is difficult to obtain.

If $f_1(x)$ and $f_2(y)$ have characteristic functions $\phi_1(u)$ and $\phi_2(u)$, then the characteristic function of the weighted sum $ax + by$ is $\phi_1(au)\phi_2(bu)$. The addition rules for common distributions (*e.g.*, that the sum of two numbers from Gaussian distributions also has a Gaussian distribution) easily follow from this observation.

Let the (partial) characteristic function corresponding to the conditional p.d.f. $f_2(x|z)$ be $\phi_2(u|z)$, and the p.d.f. of z be $f_1(z)$. The characteristic function after integration over the conditional value is

$$\phi(u) = \int \phi_2(u|z)\, f_1(z)dz \ . \tag{16.14}$$

Suppose we can write ϕ_2 in the form

$$\phi_2(u|z) = A(u)e^{ig(u)z} \ . \tag{16.15}$$

Then

$$\phi(u) = A(u)\phi_1(g(u)) \ . \tag{16.16}$$

The semi-invariants κ_n are defined by

$$\phi(u) = \exp\left(\sum_1^{\infty} \frac{\kappa_n}{n!}(iu)^n\right) = \exp\left(i\kappa_1 u - \tfrac{1}{2}\kappa_2 u^2 + \ldots\right) \ . \tag{16.17}$$

The κ_n's are related to the moments α_n and m_n. The first few relations are

$$\begin{aligned} \kappa_1 &= \alpha_1 \ (= \mu, \text{ the mean}) \\ \kappa_2 &= m_2 \ = \alpha_2 - \alpha_1^2 \ (= \sigma^2, \text{ the variance}) \\ \kappa_3 &= m_3 = \alpha_3 - 3\alpha_1\alpha_2 + 2\alpha_1^2 \ . \end{aligned} \tag{16.18}$$

16.3. Some probability distributions

Table 16.1 gives a number of common probability density functions and corresponding characteristic functions, means, and variances. Further information may be found in Refs. 1–6; Ref. 6 has particularly detailed tables. Monte Carlo techniques for generating each of them may be found in our Sec. 18.3. We comment below on all except the trivial uniform distribution.

16.3.1. ***Binomial distribution***: A random process with exactly two possible outcomes is called a *Bernoulli* process. If the probability of obtaining a certain outcome (a "success") in each trial is p, then the probability of obtaining exactly r successes ($r = 0, 1, 2, \ldots, n$) in n trials, without regard to the order of the successes and failures, is given by the binomial distribution $f(r; n, p)$ in Table 16.1. If r successes are observed in n_r trials with probability p of a success, and if s successes are observed in n_s similar trials, then $t = r + s$ is also binomial with $n_t = n_r + n_s$.

16.3.2. ***Poisson distribution***: The Poisson distribution $f(r; \mu)$ gives the probability of finding exactly r events in a given interval of x (*e.g.*, space and time) when the events occur independently of one another and of x at an average rate of μ per the given interval. The variance σ^2 equals μ. It is the limiting case $p \to 0$, $n \to \infty$, $np = \mu$ of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large μ.

Two or more Poisson processes (*e.g.*, *signal + background*, with parameters μ_s and μ_b) that independently contribute amounts n_s and n_b to a given measurement will produce an observed number $n = n_s + n_b$, which is distributed according to a new Poisson distribution with parameter $\mu = \mu_s + \mu_b$.

16.3.3. ***Normal or Gaussian distribution***: The normal (or Gaussian) probability density function $f(x; \mu, \sigma^2)$ given in Table 16.1 has mean $\overline{x} = \mu$ and variance σ^2. Comparison of the characteristic function $\phi(u)$ given in Table 16.1 with Eq. (16.17) shows that all semi-invariants κ_n beyond κ_2 vanish; this is a unique property of the Gaussian distribution. Some properties of the distribution are:

rms deviation $= \sigma$

probability x in the range $\mu \pm \sigma = 0.6827$

probability x in the range $\mu \pm 0.6745\sigma = 0.5$

expection value of $|x - \mu|$, $E(|x - \mu|) = (2/\pi)^{1/2}\sigma = 0.7979\sigma$

half-width at half maximum $= (2\ln 2)^{1/2}\sigma = 1.177\sigma$

The cumulative distribution, Eq. (16.1), for a Gaussian with $\mu = 0$ and $\sigma^2 = 1$ is related to the error function erf(y) by

$$F(x; 0, 1) = \tfrac{1}{2}\left[1 + \mathrm{erf}(x/\sqrt{2})\right] \ . \tag{16.19}$$

The error function is tabulated in Ref. 6 and is available in computer math libraries and personel computer spreadsheets. For a mean μ and variance σ^2, replace x by $(x - \mu)/\sigma$. The probability of x in a given range can be calculated with Eq. (17.29).

For x and y independent and normally distributed, $z = ax + by$ obeys $f(z;\, a\mu_x + b\mu_y,\, a^2\sigma_x^2 + b^2\sigma_y^2)$; that is, the weighted means and variances add.

The Gaussian gets its importance in large part from the *central limit theorem*: If a continuous random variable x is distributed according to *any* p.d.f. with finite mean and variance, then the sample mean, $\overline{x}_n$, of n observations of x will have a p.d.f. that approaches a Gaussian as n increases. Therefore the end result $\sum^n x_i \equiv n\overline{x}_n$ of a large number of small fluctuations x_i will be distributed as a Gaussian, even if the x_i themselves are not.

For $\boldsymbol{x}$ a set of n (not necessarily independent) Gaussian random variables x_i arranged into a column vector, the joint p.d.f. is the *multivariate Gaussian*:

$$\begin{aligned} f(\boldsymbol{x}; \boldsymbol{\mu}, V) &= \frac{1}{(2\pi)^{n/2}} \ |V|^{-1/2} \\ &\times \ \exp\left[-\tfrac{1}{2}(\boldsymbol{x} - \boldsymbol{\mu})^T \, V^{-1} \, (\boldsymbol{x} - \boldsymbol{\mu})\right] \ , \ |V| \neq 0 \ . \end{aligned} \tag{16.20}$$

Here V is the *covariance matrix* of the x's, with $V_{ii} = \mathrm{Var}(x_i)$ and $V_{ij} = E[(x_i - \mu_i)(x_j - \mu_j)] \equiv \rho_{ij}\, \sigma_i \sigma_j$, and $|V|$ is the determinant of V. (If V is singular, there is a linear relation among some of the variables, and so one should eliminate dependent variables and work with an independent set.) The quantity ρ_{ij} is the correlation coefficient for x_i and x_j, and $|\rho_{ij}|^2 \leq 1$. For $n = 2$, $f(\boldsymbol{x}; \boldsymbol{\mu}, V)$ is

$$\begin{aligned} f(x_1, x_2;\ \mu_1, \mu_2, \sigma_1, \sigma_2, \rho) &= \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \\ \times \ \exp\Bigg\{ \frac{-1}{2(1-\rho^2)} \Bigg[\frac{(x_1-\mu_1)^2}{\sigma_1^2} &- \frac{2\rho(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1\sigma_2} \\ &+ \frac{(x_2-\mu_2)^2}{\sigma_2^2} \Bigg] \Bigg\} \ . \end{aligned} \tag{16.21}$$

Table 16.1: Some common probability density functions, with corresponding characteristic functions and means and variances. In the Table, $\Gamma(k)$ is the gamma function, equal to $(k-1)!$ when k is an integer.

Distribution	Probability density function f (variable; parameters)	Characteristic function $\phi(u)$	Mean	Variance σ^2
Uniform	$f(x;a,b) = \begin{cases} 1/(b-a) & a \le x \le b \\ 0 & \text{otherwise} \end{cases}$	$\dfrac{e^{ibu} - e^{iau}}{(b-a)iu}$	$\overline{x} = \dfrac{a+b}{2}$	$\dfrac{(b-a)^2}{12}$
Binomial	$f(r;n,p) = \dfrac{n!}{r!(n-r)!}\, p^r q^{n-r}$ $r = 0,1,2,\ldots,n\ ; \quad 0 \le p \le 1\ ; \quad q = 1-p$	$(q + pe^{iu})^n$	$\overline{r} = np$	npq
Poisson	$f(r;\mu) = \dfrac{\mu^r e^{-\mu}}{r!}\ ; \quad r = 0,1,2,\ldots\ ; \quad \mu > 0$	$\exp[\mu(e^{iu} - 1)]$	$\overline{r} = \mu$	μ
Normal (Gaussian)	$f(x;\mu,\sigma^2) = \dfrac{1}{\sigma\sqrt{2\pi}}\ \exp(-(x-\mu)^2/2\sigma^2)$ $-\infty < x < \infty\ ; \quad -\infty < \mu < \infty\ ; \quad \sigma > 0$	$\exp(i\mu u - \frac{1}{2}\sigma^2 u^2)$	$\overline{x} = \mu$	σ^2
χ^2	$f(z;n) = \dfrac{z^{n/2-1}e^{-z/2}}{2^{n/2}\Gamma(n/2)}\ ; \quad z \ge 0$	$(1-2iu)^{-n/2}$	$\overline{z} = n$	$2n$
Student's t	$f(t;n) = \dfrac{1}{\sqrt{n\pi}}\ \dfrac{\Gamma[(n+1)/2]}{\Gamma(n/2)} \left(1 + \dfrac{t^2}{n}\right)^{-(n+1)/2}$ $-\infty < t < \infty\ ; \quad n$ not required to be integer	—	$\overline{t} = 0$ for $n \ge 2$	$n/(n-2)$ for $n \ge 3$
Gamma	$f(x;\lambda,k) = \dfrac{x^{k-1}\lambda^k e^{-\lambda x}}{\Gamma(k)}\ ; \quad 0 < x < \infty\ ;$ k not required to be integer	$(1 - iu/\lambda)^{-k}$	$\overline{x} = k/\lambda$	k/λ^2

The marginal distribution of any x_i is a Gaussian with mean μ_i and variance V_{ii}. V is $n \times n$, symmetric, and positive definite. Therefore for any vector $\boldsymbol{X}$, the quadratic form $\boldsymbol{X}^T V^{-1} \boldsymbol{X} = C$, where C is any positive number, traces an n-dimensional ellipsoid as $\boldsymbol{X}$ varies. If $X_i = (x_i - \mu_i)/\sigma_i$, then C is a random variable obeying the $\chi^2(n)$ distribution, discussed in the following section. The probability that $\boldsymbol{X}$ corresponding to a set of Gaussian random variables $\boldsymbol{x_i}$ lies *outside* the ellipsoid characterized by a given value of $C\,(= \chi^2)$ is given by Eq. (16.22) and may be read from Fig. 16.1. For example, the "s-standard-deviation ellipsoid" occurs at $C = s^2$. For the two-variable case ($n = 2$), the point $\boldsymbol{X}$ lies outside the one-standard-deviation ellipsoid with 61% probability. (This assumes that μ_i and σ_i are correct.) For $X_i = x_i/\sigma_i$, the ellipsoids of constant χ^2 have the same size and orientation but are centered at $\boldsymbol{\mu}$. The use of these ellipsoids as indicators of probable error is described in Sec. 17.5.1.

It is a characteristic of the multivariate Gaussian that $\rho_{ij} = 0$ is necessary and sufficient for x_i and x_j to be independent. For a given covariance matrix V, there always exist nonsingular $n \times n$ matrices H such that $HH^T = V$; H is usually upper or lower triangular in the most efficient algorithms. Then $\boldsymbol{z} = H^{-1}(\boldsymbol{x} - \boldsymbol{\mu})$ is a vector of n independent Gaussian random variables with zero mean and with a covariance matrix equal to the identity matrix.

16.3.4. χ^2 *distribution*: If $x_1, \ldots, x_n$ are independent Gaussian distributed random variables, the sum $z = \sum^n (x_i - \mu_i)^2/\sigma_i^2$ is distributed as a χ^2 with n *degrees of freedom*, $\chi^2(n)$. Under a linear transformation to n dependent Gaussian variables x_i', the χ^2 at each transformed point retains its value; then $z = \boldsymbol{X}'^T V^{-1} \boldsymbol{X}'$ as in the previous section. For a set of z_i, each of which is $\chi^2(n_i)$, $\sum z_i$ is a new random variable which is $\chi^2\,(\sum n_i)$.

Fig. 16.1 shows the confidence level (CL) obtained by integrating the tail of $f(z;n)$:

$$\mathrm{CL}(\chi^2) = \int_{\chi^2}^{\infty} f(z;\, n)\, dz\ . \tag{16.22}$$

This is shown for a special case in Fig. 16.2, and is equal to 1.0 minus the cumulative distribution function $F(z = \chi^2;\, n)$. It is useful

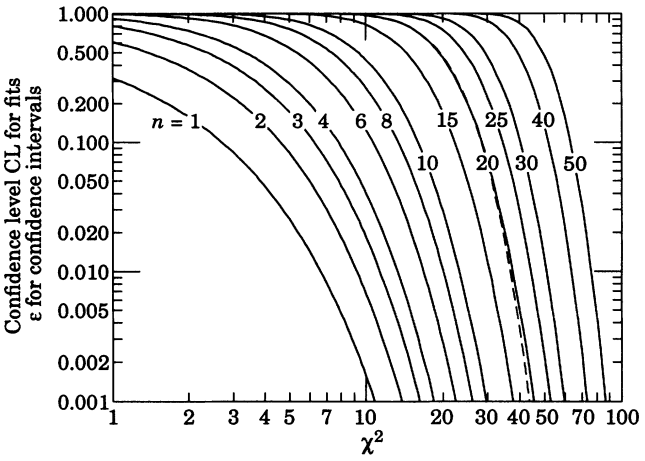

Figure 16.1: The confidence level versus χ^2 for n degrees of freedom, as defined in Eq. (16.22). The curve for a given n gives the probability that a value at least as large as χ^2 will be obtained in an experiment; *e.g.*, for $n = 10$, a value $\chi^2 \gtrsim 18$ will occur in 5% of a large number of experiments. For a fit, the CL is a measure of goodness-of-fit, in that a good fit to a correct model is expected to yield a low χ^2 (see Sec. 17.4.0). For a confidence interval, α measures the probability that the interval *does not* cover the true value of the quantity being estimated (see Sec. 17.5). The dashed curve for $n = 20$ is calculated using the approximation of Eq. (16.23).

in evaluating the consistency of data with a model (see Sec. 17): The CL is the probability that a random repeat of the given experiment would observe a greater χ^2, assuming the model is correct. It is also useful for confidence intervals for statistical estimators (see Sec. 17.5), in which case one is interested in the unshaded area of Fig. 16.2.

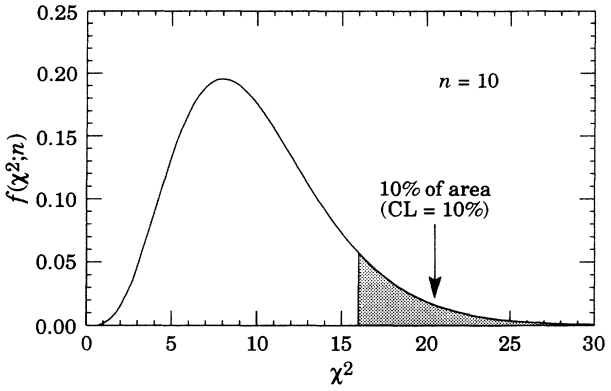

Figure 16.2: Illustration of the confidence level integral given in Eq. (16.22). This particlar example is for $n = 10$, where the area above 15.99 is 0.1.

Since the mean of the χ^2 distribution is equal to n, one expects in a "reasonable" experiment to obtain $\chi^2 \approx n$. While caution is necessary because of the width and skewness of the distribution, the "reduced χ^2" $\equiv \chi^2/n$ is a sometimes useful quantity. Figure 16.3 shows χ^2/n for useful CL's as a function of n.

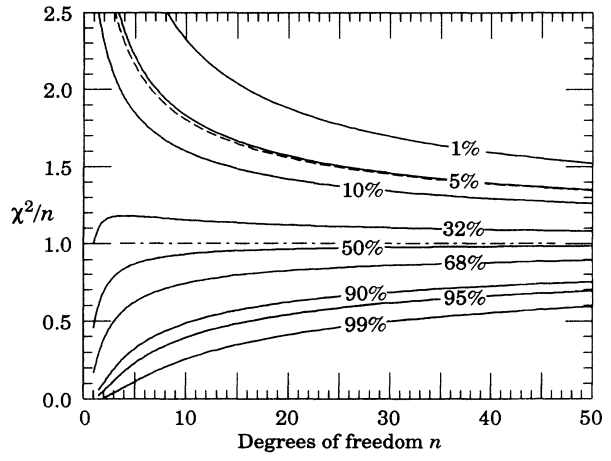

Figure 16.3: Confidence levels as a function of the "reduced χ^2" $\equiv \chi^2/n$ and the number of degrees of freedom n. Curves are labeled by the probability that a measurement will give a value of χ^2/n greater than that given on the y axis; *e.g.*, for $n = 10$, a value $\chi^2/n \gtrsim 1.8$ can be expected 5% of the time.

For large n, the CL is approximately given by [1,7]

$$\mathrm{CL}(\chi^2) \approx \frac{1}{\sqrt{2\pi}} \int_y^\infty e^{-x^2/2}\, dx \ , \qquad (16.23)$$

where $y = \sqrt{2\chi^2} - \sqrt{2n-1}$. This approximation was used to draw the dashed curves in Fig. 16.1 (for $n = 20$) and Fig. 16.3 (for CL = 5%). Since all the functions and their inverses are now readily available in standard mathematical libraries (such as IMSL, used to generate these figures, and personal computer spreadsheets, such as Microsoft® Excel [8]), the approximation (and even figures and tables) are seldom needed.

16.3.5. ***Student's t distribution***: Suppose that x and $x_1, \ldots, x_n$ are independent and Gaussian distributed with mean 0 and variance 1. We then define

$$z = \sum_1^n x_i^2 \ , \quad \text{and} \quad t = \frac{x}{\sqrt{z/n}} \ . \qquad (16.24)$$

The variable z thus belongs to a $\chi^2(n)$ distribution. Then t is distributed according to a Student's t distribution with n degrees of freedom, $f(t;n)$, given in Table 16.1.

The Student's t distribution resembles a Gaussian distribution with wide tails. As $n \to \infty$, the distribution approaches a Gaussian. If $n = 1$, the distribution is a *Cauchy* or *Breit-Wigner* distribution. The mean is finite only for $n > 1$ and the variance is finite only for $n > 2$, so for $n = 1$ or $n = 2$, t does not obey the central limit theorem.

As an example, consider the *sample mean* $\overline{x} = \sum x_i/n$ and the *sample variance* $s^2 = \sum(x_i - \overline{x})^2/(n-1)$ for normally distributed random variables x_i with unknown mean μ and variance σ^2. The sample mean has a Gaussian distribution with a variance σ^2/n, so the variable $(\overline{x} - \mu)/\sqrt{\sigma^2/n}$ is normal with mean 0 and variance 1. Similarly, $(n-1)\,s^2/\sigma^2$ is independent of this and is χ^2 distributed with $n-1$ degrees of freedom. The ratio

$$t = \frac{(\overline{x} - \mu)/\sqrt{\sigma^2/n}}{\sqrt{(n-1)\,s^2/\sigma^2\,(n-1)}} = \frac{\overline{x} - \mu}{\sqrt{s^2/n}} \qquad (16.25)$$

is distributed as $f(t;\, n-1)$. The unknown true variance σ^2 cancels, and t can be used to test the probability that the true mean is some particular value μ.

In Table 16.1, n in $f(t;n)$ is not required to be an integer. A Student's t distribution with nonintegral $n > 0$ is useful in certain applications.

16.3.6. ***Gamma distribution***: For a process that generates events as a function of x (*e.g.*, space or time) according to a Poisson distribution, the distance in x from an arbitrary starting point (which may be some particular event) to the k^{th} event belongs to a *gamma* distribution, $f(x;\, \lambda,\, k)$. The Poisson parameter μ is λ per unit x. The special case $k = 1$ (*i.e.*, $f(x;\lambda,1) = \lambda e^{-\lambda x}$) is called the *exponential* distribution. A sum of k' exponential random variables x_i is distributed as $f(\sum x_i;\, \lambda, k')$.

The parameter k is not required to be an integer. For $\lambda = 1/2$ and $k = n/2$, the gamma distribution reduces to the $\chi^2(n)$ distribution.

17. STATISTICS

Revised June 1994 with the help of R. Cousins, F. James, G. Lynch, B. P. Roe, and M. Roos

17.1. General [1–6]

A probability density function with known parameters enables us to predict the frequency with which a random variable will take on a particular value (if discrete) or lie in a given range (if continuous). In *parametric* statistics we have the opposite problem of estimating the parameters of the p.d.f. from a set of actual observations.

We refer to the true p.d.f. as the *population*; the data form a *sample* from this population. A *statistic* is any function of the data, plus known constants, which does not depend upon any of the unknown parameters. A statistic is a random variable if the data have random errors. An *estimator* is any statistic whose value is intended as a meaningful guess for the value of an unknown parameter; we denote estimators with hats, *e.g.*, $\widehat{\alpha}$.

Often it is possible to construct more than one reasonable estimator. Let α represent the true value of a parameter to be estimated; α is a vector $\boldsymbol{\alpha}$ if there is more than one parameter. Then if $\widehat{\alpha}$ is an estimator for α, desirable properties for $\widehat{\alpha}$ are: (a) *Unbiased*; bias $b = E(\widehat{\alpha}) - \alpha$, where the expectation value is taken over a hypothetical set of similar experiments in which $\widehat{\alpha}$ is constructed the same way. The bias may be due to statistical properties of the estimator or to *systematic* errors in the experiment. If we can estimate the average bias b we usually subtract it from $\widehat{\alpha}$ to obtain a new $\widehat{\alpha}' \equiv \widehat{\alpha} - b$. However, b may depend upon α or other unknowns, in which case we usually try to choose an estimator which minimizes its average size. (b) *Minimum variance*; the minimum possible value of $\mathrm{Var}(\widehat{\alpha})$ is given by the Rao-Cramér-Frechet bound:

$$\mathrm{Var}_{\mathrm{min}} = \left[1 + \partial b/\partial\alpha\right]^2 / I(\alpha) \; ; \tag{17.1}$$

$$I(\alpha) = E\left\{\left[\frac{\partial}{\partial\alpha}\sum_{i=1}^{n} \ln f(x_i;\,\alpha)\right]^2\right\} .$$

(Compare with Eq. (17.6) below.) The sum is over all data and b is the bias, if any; the x_i are assumed independent and distributed as $f(x_i;\alpha)$, and the allowed range of x must not depend upon α. The ratio $\epsilon = \mathrm{Var}_{\mathrm{min}}/\mathrm{Var}(\widehat{\alpha})$ is the *efficiency*. An *efficient* estimator (with $\epsilon = 1$) exists only for certain cases. The square root of the variance expresses the expected spread of $\widehat{\alpha}$ about its average value, as would be observed in a large number of repeats of the same measurement. (c) *Minimum mean-squared error* (mse); $\mathrm{mse} = E[(\widehat{\alpha} - \alpha)^2] = V(\widehat{\alpha}) + b^2$. The mse combines the error due to any bias quadratically with the variance, which expresses only the spread about $E(\widehat{\alpha})$, as distinct from α, the true value. (d) *Robust*; a robust estimator is not sensitive to errors in our assumptions, *e.g.*, to departures from the assumed p.d.f. due to such factors as noise.

These criteria (and others) allow us to evaluate any procedure for obtaining $\widehat{\alpha}$. In many cases these criteria conflict. The bias, variance, and mse may depend on the unknown α. In this case the optimum prescription for $\widehat{\alpha}$ may depend on the range in which we assume α to lie.

Following are techniques in common use for obtaining estimators and their standard errors $\sigma(\widehat{\alpha}) = \sqrt{\mathrm{Var}(\widehat{\alpha})}$. When the conditions of the central limit theorem are satisfied, the interval $\widehat{\alpha} \pm \sigma(\widehat{\alpha})$ forms a 68.3% *confidence interval*. This is a random interval in that its endpoints depend upon the randomly sampled data; its meaning here will be taken to be that in 68.3% of all similar experiments the interval will include the true value α. One should be aware that in most practical cases the central limit theorem is only approximately satisfied and accordingly confidence intervals which depend on that are only approximate. Confidence intervals are discussed in Section 17.5 below.

17.2. Data with a common mean

Suppose we have a set of N independent measurements y_i assumed to be unbiased measurements of the same unknown quantity μ with a common, but unknown, variance σ^2 resulting from measurement error. Then

$$\widehat{\mu} = \frac{1}{N}\sum_{i=1}^{N} y_i \tag{17.2}$$

$$\widehat{\sigma}^2 = \frac{1}{N-1}\sum_{i=1}^{N}(y_i - \widehat{\mu})^2 = \frac{N}{N-1}\left(E(y^2) - \widehat{\mu}^2\right) \tag{17.3}$$

are unbiased estimators of μ and σ^2. The variance of $\widehat{\mu}$ is σ^2/N. If the common p.d.f. of the y_i is Gaussian, these statistics are independent. Then, for large N, the variance of $\widehat{\sigma}^2$ is $2\sigma^4/N$. If the y_i are Gaussian or N is large enough that the central limit theorem applies, then $\widehat{\mu}$ is an efficient estimator for μ. Otherwise $\widehat{\mu}$ is sometimes subject to large fluctuations, *e.g.*, if the p.d.f. for y_i has long tails. In this case the median of the y_i may be a more robust estimator for μ, provided the median and mean are expected to lie at the same point in the p.d.f. for y. For Gaussian y, the median has asymptotic (large-N) efficiency $2/\pi \approx 0.64$. Student's t-distribution provides an example in which there are large tails. In this case, for large N the efficiency of the sample median relative to the sample mean is (∞, ∞, 1.62, 1.12, 0.96, 0.80, 0.64) for (1, 2, 3, 4, 5, 8, ∞) degrees of freedom.

If σ^2 is known, $\widehat{\mu}$ as given in Eq. (17.2) is still the best estimator for μ; if μ is known, substitute it for $\widehat{\mu}$ in Eq. (17.3) and replace $N-1$ by N, to obtain a somewhat better estimator $\widehat{\sigma}^2$.

If the y_i have different, known, variances σ_i^2, then

$$\widehat{\mu} = \frac{1}{w}\sum^{N} w_i\, y_i \; , \tag{17.4}$$

is an unbiased estimator for μ with smaller variance than Eq. (17.2), where $w_i = 1/\sigma_i^2$ and $w = \sum w_i$. The variance of $\widehat{\mu}$ is $1/w$.

17.3. The method of maximum likelihood

17.3.1. *General*:

"From a theoretical point of view, the most important general method of estimation so far known is the *method of maximum likelihood*" [1]. We suppose that a set of independently measured quantities x_i came from a p.d.f. $f(x;\boldsymbol{\alpha})$, where $\boldsymbol{\alpha}$ is an unknown set of parameters. The method of maximum likelihood consist of finding the set of values, $\widehat{\boldsymbol{\alpha}}$, which maximizes the joint probability density for all the data, given by

$$\mathscr{L}(\boldsymbol{\alpha}) = \prod_i f(x_i;\boldsymbol{\alpha}) \; , \tag{17.5}$$

where $\mathscr{L}$ is called the likelihood. It is usually easier to work with $\ln\mathscr{L}$, and since both are maximized for the same set of $\boldsymbol{\alpha}$, it is sufficient to solve the *likelihood equation*

$$\frac{\partial \ln\mathscr{L}}{\partial\alpha_n} = 0 \; . \tag{17.6}$$

The solution is called the *maximum likelihood estimate* of $\boldsymbol{\alpha}$. The importance of the approach is shown by the following proposition, proved in Ref. 1:

If an efficient estimate $\widehat{\boldsymbol{\alpha}}$ of $\boldsymbol{\alpha}$ exists, the likelihood equation will have a unique solution equal to $\widehat{\boldsymbol{\alpha}}$.

In evaluating $\mathscr{L}$, it is important that any normalization factors in the f's which involve $\boldsymbol{\alpha}$ be included. However, we will only be interested in the maximum of $\mathscr{L}$ and in ratios of $\mathscr{L}$ at different $\boldsymbol{\alpha}$'s; hence any multiplicative factors which do not involve the parameters

we want to estimate may be dropped; this includes factors which depend on the data but not on $\boldsymbol{\alpha}$.

If the solution to Eq. (17.6) is at a maximum, $\partial \ln \mathscr{L}/\partial \alpha_n$ will have negative slope in its vicinity. In many practical problems, one often uses nonlinear algorithms for finding the maximum, and must be alert to various possibilities for error: (a) Eq. (17.6) may yield a minimum, therefore one must check the second derivative; (b) there may be more than one maximum—one must try to find the global maximum; (c) the global maximum may lie at a boundary of the physical region, in which case Eq. (17.6) will not find it.

If an unbiased, efficient estimator exists, this method will find it. If $\partial \ln \mathscr{L}/\partial \alpha_n$ is linear in the vicinity of the root, an efficient estimator is guaranteed; other efficient cases are discussed in the literature. For large data samples, the central limit theorem will usually assure this condition in some significant neighborhood of zero; hence the estimator is usually efficient in that case, provided certain conditions are met (*e.g.*, that the solution does not lie on a boundary). In this case, in the neighborhood of the maximum $\ln \mathscr{L}$ is a downward-curving paraboloid and $\mathscr{L}$ is proportional to a multivariate Gaussian.

The results of two or more experiments may be combined by forming the product of the $\mathscr{L}$'s, or the sum of the $\ln \mathscr{L}$'s.

Under a one-to-one change of parameters from $\boldsymbol{\alpha}$ to $\boldsymbol{\beta} = \boldsymbol{\beta}(\boldsymbol{\alpha})$, the maximum likelihood estimate is simply $\boldsymbol{\beta}(\widehat{\boldsymbol{\alpha}})$, given the solution $\widehat{\boldsymbol{\alpha}}$ for $\boldsymbol{\alpha}$. That is, the maximum likelihood solution for $\boldsymbol{\beta}$ is found by simple substitution of $\widehat{\boldsymbol{\alpha}}$ into the transformation equation. It is possible that the new solution $\widehat{\boldsymbol{\beta}}$ will be a biased solution for the true value of $\boldsymbol{\beta}$ even if $\widehat{\boldsymbol{\alpha}}$ is not biased, and vice-versa. In the asymptotic limit (of large amounts of data) both $\widehat{\boldsymbol{\alpha}}$ and $\widehat{\boldsymbol{\beta}}$ will (usually) converge to unbiased solutions, but at different rates.

Except in special cases like the least-squares method, the value of the likelihood function at the solution does not necessarily tell us whether the final fit was a sensible description of the data or not. In special cases such as the one discussed in Sec. 17.3.3, one can define a quantity which approaches the χ^2-distribution in the limit of a large number of counts in the experiment, but in general some other strategy must be used. For example, data generated by Monte Carlo simulations of the experiment can be analyzed by the same method. If the experimental likelihood is lower than that of some agreed-upon fraction of these results, one should question the appropriateness of the p.d.f. At the same time one can check for bias in the solution.

17.3.2. *Error estimates*:

The covariance matrix V may be estimated from

$$V_{nm} = \left(E\left[-\frac{\partial^2 \ln \mathscr{L}}{\partial \alpha_n \, \partial \alpha_m}\bigg|_{\widehat{\alpha}} \right] \right)^{-1} . \tag{17.7}$$

If $\partial \ln \mathscr{L}/\partial \alpha_n$ is linear, the "expectation" operation in Eq. (17.7) has no effect because the second derivative of $\ln \mathscr{L}$ is constant. Otherwise, it may be approximated by taking the average of the quantity in square brackets over a range of α_n and α_m near the solution. For complex cases it may be more practical to evaluate s-standard-deviation errors from the contour

$$\ln \mathscr{L}(\boldsymbol{\alpha}) = \ln \mathscr{L}_{\max} - s^2/2 \, , \tag{17.8}$$

where $\ln \mathscr{L}_{\max}$ is the value of $\ln \mathscr{L}$ at the solution point (compare with Eq. (17.27), below). The extreme limits of this contour parallel to the α_n axis give an approximate s-standard-deviation confidence interval in α_n. These intervals may not be symmetric and they may even consist of two or more disjoint intervals. This procedure gives one-standard-deviation errors in α_n equal to $\sqrt{V_{nn}}$ (not summed) of Eq. (17.7) if the estimator is efficient. If it is not efficient, the level of confidence implied by the value of s is only approximate.

17.3.3. *Application to Poisson-distributed data*:

In the case of Poisson-distributed data in a counting experiment, the unbinned maximum likelihood method (where the index i in Eq. (17.5) labels events) is preferred if the total the number of events is very small. If there are enough events to justify binning them in a histogram, then one may alternatively maximize the likelihood function for the contents of the bins (so i labels bins). This is equivalent to minimizing [7]

$$\chi^2 = \sum_i \left[2(N_i^{\rm th} - N_i^{\rm obs}) + 2N_i^{\rm obs} \ln(N_i^{\rm obs}/N_i^{\rm th}) \right] . \tag{17.9}$$

where $N_i^{\rm obs}$ and $N_i^{\rm th}$ are the observed and theoretical (from f) contents of the ith bin. In bins where $N_i^{\rm obs} = 0$, the second term is zero. This function asymptotically behaves like a classical χ^2 for purposes of point estimation, interval estimation, *and goodness-of-fit.* It also guarantees that the area under the fitted function f is equal to the sum of the histogram contents (as long as the overall normalization of f is effectively left unconstrained during the fit), which is not the case for χ^2 statistics based on a least-squares procedure with traditional weights.

17.4. Method of least squares

The *method of least squares* can be derived from the maximum likelihood theorem. We suppose a set of N measurements at points x_i. The ith measurement y_i is assumed to be chosen from a Gaussian distribution with mean $F(x_i;\boldsymbol{\alpha})$ and variance σ_i^2. Then

$$\chi^2 = -2 \ln \mathscr{L} + \text{constant} = \sum_1^N \frac{[y_i - F(x_i;\boldsymbol{\alpha})]^2}{\sigma_i^2} \, . \tag{17.10}$$

Finding the set of parameters $\boldsymbol{\alpha}$ which maximizes $\mathscr{L}$ is equivalent to finding the set which minimizes χ^2.

In many practical cases one further restricts the problem to the situation in which $F(x_i;\boldsymbol{\alpha})$ is a linear function of the α_m's,

$$F(x_i;\boldsymbol{\alpha}) = \sum_n \alpha_n \, f_n(x) \, , \tag{17.11}$$

where the f_n are k linearly independent functions (*e.g.*, 1, x, x^2, ..., or Legendre polynomials) which are single-valued over the allowed range of x. We require $k \leq N$, and at least k of the x_i must be distinct. We wish to estimate the linear coefficients α_n. Later we will discuss the nonlinear case.

If the point errors $\epsilon_i = y_i - F(x_i;\boldsymbol{\alpha})$ are Gaussian, then the minimum χ^2 will be distributed as a χ^2 random variable with $n = N - k$ degrees of freedom. We can then evaluate the goodness-of-fit (confidence level) from Figs. 16.1 or 16.3, as per the earlier discussion. The confidence level expresses the probability that a *worse* fit would be obtained in a large number of similar experiments under the assumptions that: (a) the model $y = \sum \alpha_n \, f_n$ is correct and (b) the errors ϵ_i are Gaussian and unbiased with variance σ_i^2. If this probability is larger than an agreed-upon value (0.001, 0.01, or 0.05 are common choices), the data are *consistent* with the assumptions; otherwise we may want to find improved assumptions. As for the converse, most people do not regard a model as being truly *inconsistent* unless the probability is as low as that corresponding to four or five standard deviations for a Gaussian (6×10^{-3} or 6×10^{-5}; see Sec. 17.5.1). If the ϵ_i are not Gaussian, the method of least squares still gives an answer, but the goodness-of-fit test would have to be done using the correct distribution of the random variable which is still called "χ^2."

Finding the minimum of χ^2 in the linear case is straightforward:

$$\begin{aligned} -\frac{1}{2}\frac{\partial \chi^2}{\partial \alpha_m} &= \sum_i f_m(x_i) \left(\frac{y_i - \sum_n \alpha_n \, f_n(x_i)}{\sigma_i^2} \right) \\ &= \sum_i \frac{y_i \, f_m(x_i)}{\sigma_i^2} - \sum_n \alpha_n \sum_i \frac{f_n(x_i) \, f_m(x_i)}{\sigma_i^2} \, . \end{aligned} \tag{17.12}$$

With the definitions

$$g_m = \sum_i y_i \, f_m(x_i)/\sigma_i^2 \tag{17.13}$$

and

$$(V_{\widehat{\alpha}}^{-1})_{mn} = \sum_i f_n(x_i) \, f_m(x_i)/\sigma_i^2 \, , \tag{17.14}$$

the k-element column vector of solutions $\widehat{\alpha}$, for which $\partial\chi^2/\partial\alpha_m = 0$ for all m, is given by

$$\widehat{\alpha} = V_{\widehat{\alpha}} \, g \, . \tag{17.15}$$

Non-independent y_i's

More generally, the measured y_i's are not independent. Then the set of σ_i^2's must be replaced by the $N \times N$ covariance matrix V_y. Then, if H is the $N \times k$ matrix with element $H_{in} = f_n(x_i)$, the solution $\widehat{\alpha}$ is given by the solution to the *normal equation*

$$(H^T \, V_y^{-1} \, H) \, \widehat{\alpha} = H^T \, V_y^{-1} \, y \, , \tag{17.16a}$$

or, formally,

$$\widehat{\alpha} = (H^T \, V_y^{-1} \, H)^{-1} \, H^T \, V_y^{-1} \, y \equiv D y \, , \tag{17.16b}$$

where y is the N-element vector of measured y_i's. The normal equations may be solved by numerical methods much more computationally efficient than brute application of Eq. (17.16b). In particular, $H^T \, V_y^{-1} \, H$ is sometimes singular or nearly singular. In such cases there is at least one f_n which may be expressed as a linear combination of others (or nearly so) when evaluated at the data points. The best procedure is usually to drop such functions from the expansion (or set $\widehat{\alpha}_n = 0$). See Press [8], Maindonald [9], or Basilevsky [10] for discussions.

In terms of the $k \times N$ matrix D, the standard covariance matrix for the $\widehat{\alpha}$ is estimated by

$$V_{\widehat{\alpha}} = D \, V_y \, D^T \, . \tag{17.17}$$

If the measured y_i's are independent, V_y is diagonal with ii^{th} element σ_i^2 and $V_{\widehat{\alpha}}$ is obtained from Eq. (17.14) above.

The expected covariance [see Eq. (16.9)] of $\widehat{\alpha}_n$ and $\widehat{\alpha}_m$ is estimated by

$$E\left[(\alpha_n - \widehat{\alpha}_n)(\alpha_m - \widehat{\alpha}_m)\right] = (V_{\widehat{\alpha}})_{nm} \, . \tag{17.18}$$

Even when the y_i's are independent (diagonal V_y), $\widehat{\alpha}_n$ and $\widehat{\alpha}_m$ may not be (nondiagonal $V_{\widehat{\alpha}}$). For the model function $y = \sum \alpha_n \, f_n(x)$, the estimated variance of an interpolated or extrapolated value of y at a point x is

$$E\left[(y - \widehat{y})^2\right] = \sigma^2(y)$$

$$= \sum_{n,m} (V_{\widehat{\alpha}})_{nm} \, f_n(x) \, f_m(x) \, . \tag{17.19}$$

Example: straight-line fit

For the case of a straight-line fit, $y(x) = \alpha_1 + \alpha_2 \, x$, one obtains, for independent measurements y_i, the following estimates of α_1 and α_2,

$$\widehat{\alpha}_1 = (g_1 \, S_{22} - g_2 \, S_{12})/D \, , \tag{17.20}$$

$$\widehat{\alpha}_2 = (g_2 \, S_{11} - g_1 \, S_{12})/D \, , \tag{17.21}$$

where

$$(S_{11}, \, S_{12}, \, S_{22}) = \sum (1, \, x_i, \, x_i^2)/\sigma_i^2 \, , \tag{17.22a}$$

$$(g_1, \, g_2) = \sum (1, \, x_i) y_i/\sigma_i^2 \, . \tag{17.22b}$$

respectively, and

$$D = S_{11} \, S_{22} - S_{12}^2 \, . \tag{17.23}$$

The covariance matrix of the fitted parameters is:

$$\begin{pmatrix} V_{11} & V_{12} \\ V_{12} & V_{22} \end{pmatrix} = \frac{1}{D} \begin{pmatrix} S_{22} & -S_{12} \\ -S_{12} & S_{11} \end{pmatrix} \, . \tag{17.24}$$

The estimated variance of an interpolated or extrapolated value of y at point x is:

$$(\widehat{y} - y_{\text{true}})^2 \Big|_{\text{est}} = \frac{1}{S_1} + \frac{S_1}{D} \left(x - \frac{S_x}{S_1} \right)^2 \, . \tag{17.25}$$

17.4.1. *General comments*:

If y is not linear in the fitting parameters α_n, or if the errors σ_i depend upon y and therefore on α_n, the solution vector may have to be found by iteration of Eqs. (17.13)–(17.15) or Eq. (17.16b). The same results may be obtained by numerical techniques from the sum of squares, χ^2, directly, if we have a reasonable first guess α_0 for the solution vector:

$$\widehat{\alpha} = \alpha_0 - \left(\frac{\partial^2\chi^2}{\partial\alpha^2} \right)_{\alpha_0}^{-1} \cdot \left. \frac{\partial\chi^2}{\partial\alpha} \right|_{\alpha_0} \tag{17.26a}$$

and

$$V_{\widehat{\alpha}} = 2 \left(\frac{\partial^2\chi^2}{\partial\alpha^2} \right)_{\widehat{\alpha}}^{-1} \, , \tag{17.26b}$$

where $\partial\chi^2/\partial\alpha$ is a k-element vector whose n^{th} element is $\partial\chi^2/\partial\alpha_n$, $\partial^2\chi^2/\partial\alpha^2$ is a $k \times k$ matrix with mn^{th} element $\partial^2\chi^2/(\partial\alpha_m \cdot \partial\alpha_n)$, and all derivatives are to be evaluated at the points indicated. If "χ^{2n}" is a true χ^2, the second-derivative matrix is independent of α; therefore the shape of the χ^2 as a function of α is a paraboloid and Eq. (17.26a) will give the solution immediately. Otherwise one may need to iterate Eq. (17.26a) to arrive at a solution (Newton-Raphson method). The CERN program MINUIT [11] offers several iteration schemes for solving such problems.

Note that in Eq. (17.16b), one needs only a matrix proportional to V_y to find $\widehat{\alpha}$. Hence, for example, if the variances σ_i^2 of the errors are unknown but assumed equal and independent, and $E(\epsilon_i) = 0$, one can still solve for $\widehat{\alpha}$. One cannot, however, solve for $V_{\widehat{\alpha}}$ or evaluate goodness-of-fit. These can be estimated from the *residuals*, $r_i = \widehat{y}(x_i) - y_i$, where $\widehat{y}(x_i)$ is the fitted curve at x_i, because study of the r_i enables one to estimate V_y. In addition, the residuals can be used to look for evidence of bias such as trends in the data not incorporated in the model [4].

The errors on the solution $\widehat{\alpha}$ are independent of the value of χ^2 at minimum—they depend only upon the shape about the minimum. Eq. (17.26b) implies that s-standard-deviation limits on the elements of $\widehat{\alpha}$ are given by the set of α' such that

$$\chi^2(\alpha') = \chi^2_{\text{min}} + s^2 \, ; \tag{17.27}$$

(This is a special case of Eq. (17.8).) This equation, which defines a contour in α-space, is often convenient for estimating errors in applications of least-squares techniques to nonlinear cases, where the second derivative [Eq. (17.26b)] may be a rapidly varying function of α. If the problem is highly nonlinear, all such contours are, at best, only approximations to desired exact confidence regions which would have some given probability of covering the true value of α. It may be that Eq. (17.27) will define a set of disjoint regions. In addition, iteration of Eq. (17.26a) may require sophisticated techniques [8,11] to reach convergence in a practical amount of computation. For example, in cases involving many variables in α, especially if the correlations are large, simplex or other techniques which do not involve explicit calculation of derivatives are often to be preferred. Such techniques are designed to find their way through complicated nonlinear problems without diverging to infinite α (unless the minimum is actually at infinity).

The method of least squares is sometimes used in cases where the distribution is not Gaussian or not known to be Gaussian. In such cases it can still be used, but it is then not a special case of the maximum-likelihood method, and the theorems having to do with that approach no longer apply. However, if (a) the distribution of $y_i - \sum \alpha_k f_k(x_i)$ has an expectation value of zero (unbiased) and (b) has a finite, known, fixed variance σ_i^2 (does not depend on α), then estimates of α obtained by minimizing χ^2 will be unbiased and have the smallest possible variance of all linear unbiased estimates (Gauss-Markov theorem). This statement is more general than the least-squares method as a special case of the maximum likelihood method in that the distributions do not have to be Gaussian, but more restrictive in that it applies only when the fitting function is linear in the α_k's.

For example, in counting experiments one often groups the data in bins in order to associate a Poisson error with each bin. In this case y_i is the bin height and the error depends on the expectation value of the theory in each bin, as estimated by the best fit of the model. Since the variances are functions of the fitting parameters, neither the conditions of the Gauss-Markov theorem nor the assumption of Gaussian distributions (with or without fixed variances) in the context of the maximum likelihood approach are valid without a large-number approximation, and so an unbiased or efficient least-squares fit is not guaranteed. In such cases it seems more sensible to use one of the approaches discussed in Sec. 17.3.3.

17.5. Errors and confidence intervals

We measure a mass, lifetime, or other physical quantity under the assumption that a "true answer" α exists. The conditions of the measurement introduce a random element, and our measurement (or combination of measurements) $\hat{\alpha}_{\rm exp}$ samples a distribution with p.d.f. $f(\hat{\alpha};\alpha)$. The unknown constant α appears as a parameter. We suppose that for every value of α we can find two values $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$ such that repeated experiments would produce results in the interval $\gamma_1 < \hat{\alpha} < \gamma_2$ a fraction $1-\varepsilon$ of the time, where

$$1-\varepsilon = \int_{\gamma_1}^{\gamma_2} f(\hat{\alpha};\alpha)\, d\hat{\alpha}\ . \tag{17.28}$$

This situation is shown in Fig. 17.1 (ignore the "unphysical region" part of the graph for now), where the region between the curves $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$ is indicated by the domain $D(\varepsilon)$. It can be argued that since the point $(\alpha_{\rm actual}, \hat{\alpha}_{\rm exp})$ belongs to D, then our statement that repeated experiments would produce values of $\hat{\alpha}$ in the interval $\gamma_1 < \hat{\alpha} < \gamma_2$ is equivalent to the statement that the *confidence interval* $c_1 < \alpha < c_2$ includes $\alpha_{\rm actual}$ with probability $1-\varepsilon$ [1,6]. (We will call ε the *confidence coefficient*.) In this "confidence interval" or frequentist approach, α is a parameter, not a statistical variable. Instead, c_1 and c_2 vary from experiment to experiment and *are* statistical variables. It is very different to say that a lifetime τ is to be found in the interval $\tau_0 \pm \sigma_\tau$ with 68% probability than to say that the interval $\tau_0 \pm \sigma_\tau$ (which can vary from experiment to experiment) includes the actual, fixed, value of the lifetime with 68% probability.

The actual choice of γ_1 and γ_2, such that $\int_{\gamma_1}^{\gamma_2} f(\hat{\alpha};\alpha)\, d\hat{\alpha} = 1-\varepsilon$, can be made in an infinite number of ways, but in practical situations there are usually additional criteria. For a Gaussian distribution, for example, choosing the limits symmetric about the mean minimizes the length of the interval. The area of the excluded tail on either side is then $\varepsilon/2$. For a Poisson distribution negative values cannot occur, so $\gamma(\hat{\alpha},\alpha)$ (with $\hat{\alpha}$ an integer and α the Poisson mean) might be taken as the curve below which ε of the area under the distribution lies. (In this case the curve really consists of discrete points, since $\hat{\alpha}$ can have only discrete values.) For $\varepsilon = 0.05$ the curve starts at $(\alpha,\hat{\alpha}) = (3.0, 0)$. If in a given experiment no decays to a certain final state are seen, we might then conclude that $\alpha < 3.0$ excludes the actual value of α with 95% probability. This statement can be converted to a similar statement about the branching fraction.

In Sec. 16 we discussed such confidence limits for a χ^2 distribution (where ε was called CL). Here we discuss confidence intervals for the Gaussian and Student's t-distribution, and confidence limits for the Poisson case. We then discuss the much more contentious situation in which the horizontal line at ordinate $\hat{\alpha}$ in Fig. 17.1 enters $D(\varepsilon)$ at a boundary for unphysical values of α, so that at least c_1 is undefined—for example, if we find $\hat{m}^2 = -30 \pm 50\ {\rm eV}^2$.

Extensive tables and graphs were once used to find confidence intervals and limits, but by now their main function is to confirm that software is working. FORTRAN mathematical libraries (IMSL, NAG, CERNLIB) are readily available, and a wide range of distributions are available in personal computer spreadsheet applications such as Microsoft® Excel [12]. Its built-in functions CHIDIST, NORMDIST, and TDIST (Student's t-distribution), along with "Solver," were used to produce or check the numbers given in this section.

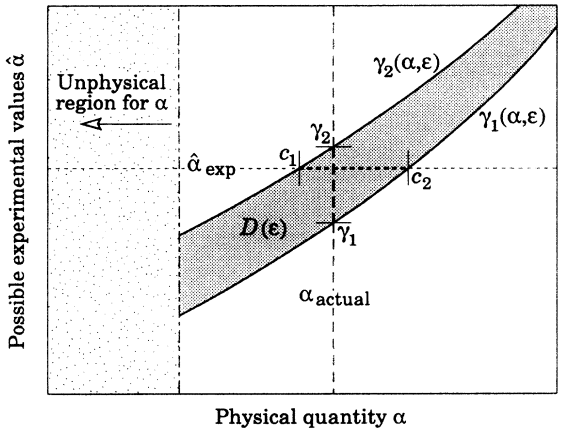

Figure 17.1: Confidence intervals for a single unknown parameter α. One might think of the p.d.f. $f(\hat{\alpha};\alpha)$ as being plotted out of the paper as a function of $\hat{\alpha}$ along each vertical line of constant α. The domain $D(\varepsilon)$ contains a fraction $1-\varepsilon$ of the area under each of these functions.

17.5.1. *Gaussian errors*:

If the data are such that the distribution of the estimator(s) satisfies the central limit theorem discussed in Sec. 16.3.3, the Gaussian distribution is the basis of the error analysis. If there is more than one parameter being estimated, the multivariate Gaussian is used. For the univariate case with known σ,

$$1-\varepsilon = \int_{\hat{\mu}-\delta}^{\hat{\mu}+\delta} f(x;\,\hat{\mu},\,\sigma^2)\, dx = {\rm erf}\left(\frac{x-\hat{\mu}}{\sqrt{2}\,\sigma}\right) \tag{17.29}$$

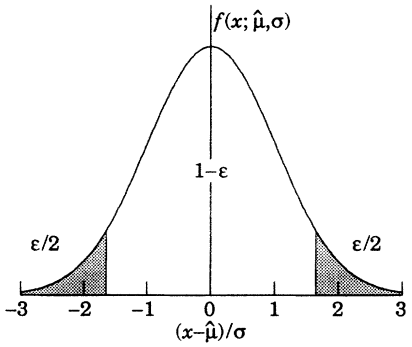

Figure 17.2: Illustration of a symetric 90% confidence interval (unshaded) for a measurement of a single quantity with Gaussian errors. Integrated probabilities, defined by ε, are as shown.

is the probability that the true value of μ will fall within $\pm\delta$ ($\delta > 0$) of the measured $\hat{\mu}$. This interval will cover μ in a fraction $1-\varepsilon$ of all similar measurements. Fig. 17.2 shows a $\delta = 1.64\sigma$ confidence interval unshaded. The choice $\delta = \sqrt{{\rm Var}(\hat{\mu})} \equiv \sigma$ gives an interval called the *standard error* which has $1-\varepsilon = 68.27\%$ if σ is known. Confidence coefficients ε for other frequently used choices of δ are given in Table 17.1.

For other δ, find ε as the ordinate of Fig. 16.1 on the $n = 1$ curve at $\chi^2 = (\delta/\sigma)^2$. We can set a one-sided (upper or lower) limit by excluding above $\hat{\mu} + \delta$ (or below $\hat{\mu} - \delta$); ε's for such limits are 1/2 the values in the table above.

We have increased confidence that the interval covers the true value as $1-\varepsilon$ increases, or χ^2 increases. We must be careful to distinguish this case from the other major use of Fig. 16.1, evaluation of goodness-of-fit (Sec. 17.4.0). In that case we have increased confidence

Table 17.1: Area of the tails ε outside $\pm\delta$ from the mean of a Gaussian distribution.

ε (%)	δ	ε (%)	δ
31.73	1σ	20	1.28σ
4.55	2σ	10	1.64σ
0.27	3σ	5	1.96σ
6.3×10^{-3}	4σ	1	2.58σ
5.7×10^{-5}	5σ	0.1	3.29σ
2.0×10^{-7}	6σ	0.01	3.89σ

in the fit as χ^2 decreases. In an attempt to reduce possible confusion in this discussion, we will use the ε notation (which corresponds to notation used in hypothesis testing [4]) when discussing confidence intervals and CL notation when discussing goodness-of-fit. Elsewhere in this *Review*, where the confusion between fit confidence level and interval (usually an upper or lower limit) confidence level does not arise, we follow the common practice of using "CL" to refer to the confidence level of the interval. This CL is understood to represent $1-\varepsilon$.

If the variance σ^2 of the estimator is not known, but must be estimated from the data, then we need to incorporate the error in $\widehat{\sigma}$ into our confidence interval using Student's t distribution. If we have N data points with which we estimate k parameters, the Gaussian approximation is adequate for $N-k \gg 1$. Otherwise replace δ by a factor $T\widehat{\sigma}$, T being defined by

$$1-\varepsilon = \int_{-T}^{T} f(t; N-k)\, dt \ , \tag{17.30}$$

where f for the Student's t-distribution is defined in Table 16.1. T is tabulated in Ref. 13 and in Table 17.2.

Table 17.2: t limits containing $1-\varepsilon$ of the area of Student's t-distribution $f(t; N-k)$.

	ε (%)					
$N-k$	31.67	10.00	5.00	4.55	1.00	0.27
1	1.84	6.31	12.71	13.97	63.66	235.78
2	1.32	2.92	4.30	4.53	9.92	19.21
3	1.20	2.35	3.18	3.31	5.84	9.22
4	1.14	2.13	2.78	2.87	4.60	6.62
5	1.11	2.01	2.57	2.65	4.03	5.51
10	1.05	1.81	2.23	2.28	3.17	3.96
20	1.03	1.72	2.09	2.13	2.85	3.42
∞	1.00	1.64	1.96	2.00	2.58	3.00

For multivariate $\boldsymbol{\alpha}$ we must consider pairwise correlations. Assuming a multivariate Gaussian, Eq. (16.20), and subsequent discussion the standard error ellipse for the pair $(\widehat{\alpha}_m, \widehat{\alpha}_n)$ may be drawn as in Fig. 17.3.

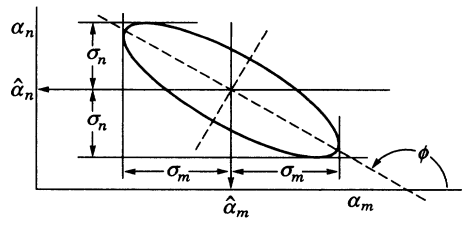

Figure 17.3: Standard error ellipse for the estimators $\widehat{\alpha}_m$ and $\widehat{\alpha}_n$. In this case the correlation is negative.

The minimum χ^2 or maximum likelihood solution is at $(\widehat{\alpha}_m, \widehat{\alpha}_n)$. The standard errors σ_m and σ_n are defined as shown, where the ellipse is at a constant value of $\chi^2 = \chi^2_{\rm min} + 1$ or $\ln\mathscr{L} = \ln\mathscr{L}_{\rm max} - 1/2$. The angle of the major axis of the ellipse is given by

$$\tan 2\phi = \frac{2\rho_{mn}\,\sigma_m\,\sigma_n}{\sigma_m^2 - \sigma_n^2} \ . \tag{17.31}$$

For non-Gaussian or nonlinear cases, one may construct an analogous contour from the same χ^2 or $\ln\mathscr{L}$ relations. Any other parameters $\widehat{\alpha}_\ell, \ell \neq m, n$ must be allowed freely to find their optimum values for every trial point.

For any unbiased procedure (*e.g.*, least squares or maximum likelihood) being used to estimate k parameters α_i, $i = 1, \ldots, k$, the probability $1-\varepsilon$ that the true values of all k lie within the s-standard deviation ellipsoid may be found from Fig. 16.1. Read the ordinate as ε; the correct value of ε occurs on the $n = k$ curve at $\chi^2 = s^2$. For example, for $k = 2$, the probability that the true values of α_1 and α_2 simultaneously lie within the one-standard-deviation error ellipse ($s = 1$), centered on $\widehat{\alpha}_1$ and $\widehat{\alpha}_2$, is 39%. This probability only assumes Gaussian errors, unbiased estimators, and that the model describing the data in terms of the α_i is correct.

17.5.2. *Poisson processes—upper limits*:

Because the outcome of a Poisson process is an integral number of events, n_0, it is usually not possible to set confidence intervals for the true Poisson parameter μ at a certain exact ε. For large n_0 an approximate interval can be set using the Gaussian approximation, in our section on Probability, Sec. 16.3.2, and the techniques of Sec. 17.5.1.

For small n_0 we can define an upper limit N for μ as being that value of μ such that it would be at least $1-\varepsilon$ (*e.g.*, 90% or 95%) probable that a random observation of n would then lie above the observed n_0. Thus

$$1-\varepsilon = \sum_{n=n_0+1}^{\infty} f(n; N) \ ; \qquad \varepsilon = \sum_{n=0}^{n_0} f(n; N) \ . \tag{17.32}$$

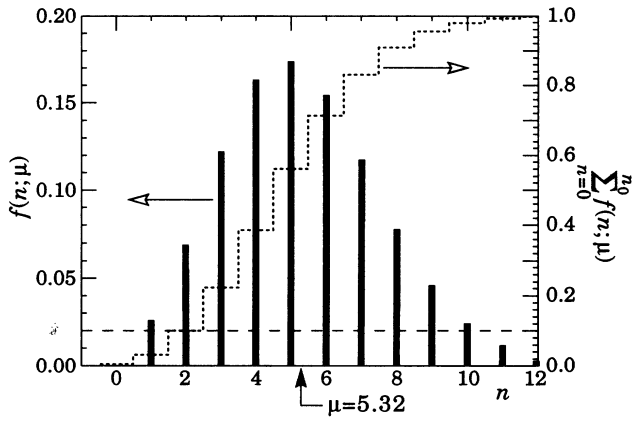

Figure 17.4: Illustration of Eq. (17.32) Poisson probabilities for an assumed mean of N. With an observed count $n_0 = 2$, $N = 5.3$ as shown gives summed probability $1-\varepsilon = 90\%$. The dotted summmed probability curve (scale on right) has been displaced by -0.5 for clarity.

Fig. 17.4 illustrates the case with $n_0 = 2$ and $1-\varepsilon = 90\%$, for which it may be shown that $N = 5.3$. For any given n_0 and desired ε we can obtain N from the χ^2 Confidence Level figure because of a relation between the Poisson and the χ^2: read the ordinate as ε, find χ^2 on the curve for $n = 2(n_0+1)$; then $N = \chi^2/2$. Some useful values are given in Table 17.3.

The meaning of these upper limits is that, for a given true μ, the probability is *at least* $1-\varepsilon$ that one will observe n_0 which will result in N which is $\geq \mu$. The probability for that to occur may be higher than $1-\varepsilon$; for example, if $\mu \leq 2.30$ a "90%" upper limit will actually exceed μ 100% of the time. Note from Eq. (17.32) that for $n_0 = 0$, $N = -\ln\varepsilon$.

Table 17.3: Poisson upper limits N for n_0 observed events.

n_0	$\varepsilon =$ 10%	$\varepsilon =$ 5%	n_0	$\varepsilon =$ 10%	$\varepsilon =$ 5%
0	2.30	3.00	6	10.53	11.84
1	3.89	4.74	7	11.77	13.15
2	5.32	6.30	8	13.00	14.44
3	6.68	7.75	9	14.21	15.71
4	7.99	9.15	10	15.41	16.96
5	9.27	10.51	11	16.60	18.21

17.5.3. *Bounded physical region**:

The measurement of a physical constant α results in an estimator $\widehat{\alpha}$, together with some knowledge of experimental error and therefore knowledge of $f(\widehat{\alpha};\alpha)$, the parameterized p.d.f. that allows us to state the probability with which repeated experiments would produce results in a given range. It does *not* permit us to comment about α itself, which in this language is a constant, not a statistical variable. At the beginning of this section we introduced the confidence interval, or frequentist, approach to the problem, and were able to say that with a given probability the unknown parameter could be found between (statistical) limits c_1 and c_2. But what if a physical boundary exists? Although polarization should be less than one and mass or its square should be greater than zero, experimental results do not always fall inside such a physical boundary because of statistical fluctuations.

However one might set a limit, there is little question about how to report and combine data [14]. A given experiment finds an unbiased estimator $\widehat{\alpha} = -5 \pm 10$ for a physical constant (*e.g.* the square of the mass of a neutrino, in eV^2). This value should be reported as the primary result. In case the true value is zero, for example, this "unphysical" result would not be unlikely. It can be combined with the results of other such experiments by forming the appropriately weighted average of unbiased results, including negative ones, to find an unbiased estimator which expresses our best knowledge of the parameter.

What if we wish to extend our concept of confidence limit to such a situation? The question of how to calculate an upper limit in the vicinity of a physical boundary is one of the most divisive in high-energy physics. We present two main approaches: The confidence interval, or frequentist, method, and the Bayesian method. "Classical method" is applied to one or the other by various writers, so we avoid the term.

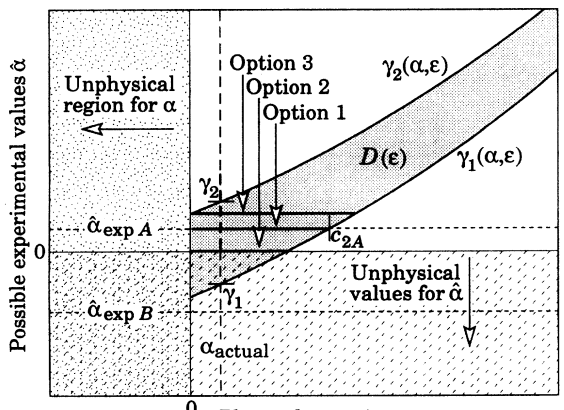

Figure 17.5: The situation near a physical boundary. In Fig. 17.1 the horizontal line for a given $\widehat{\alpha}_{\mathrm{exp}}$ crossed the domain $D(\varepsilon)$, bounded by $\gamma_1(\alpha,\epsilon)$ and $\gamma_2(\alpha,\epsilon)$ entirely in the physical region, entering at c_1 and leaving at c_2. The limits γ_1 and γ_2 cannot be defined in a region where α is not defined, so the functions cannot be continued into the unphysical region. As a result c_1 (for experiment A) or c_1 and c_2 (for experiment B) cannot be defined. Options 1, 2, and 3 label the ways one might define confidence intervals, as described in the text.

1. The method of confidence intervals [1,15]. This is the approach described in the introduction, and requires little further explanation. It is presently the method in favor [1,6,14]. For a Gaussian distribution it gives the same result as the Bayesian approach with a flat prior distribution (see below) if the region containing α with the stated probability is far from an unphysical region, as in Fig. 17.1. Two cases in which this is untrue are shown in Fig. 17.5, where as a matter of convenience we assume that α must be positive. As before, we can define limits γ_1 and γ_2 for each value of the unknown parameter α, such that we can expect that a fraction $1-\varepsilon$ of repeated experiments to produce results between these limits. Since this can be done for each value of α, the limits are described by the functions $\gamma_1(\alpha,\varepsilon)$ and $\gamma_2(\alpha,\varepsilon)$. However, these *cannot* be extended into a region in which α makes no sense. Experimental result $\widehat{\alpha}_{\mathrm{exp}\,A}$, indicated in Fig. 17.5, is positive, but if the true value is α_{actual} a significant fraction of repetitions of the experiment would produce negative $\widehat{\alpha}$. In these cases there is no horizontal intercept c_1, so without further assumptions we cannot make a statement about the region which would cover α_{actual} in a given fraction of experiments. Experimental result $\widehat{\alpha}_{\mathrm{exp}\,B}$ presents a more serious problem, since it is so negative that there is no physical α for which the point $(\widehat{\alpha},\alpha)$ lies in the domain $D(\varepsilon)$. The reason why the frequentist method gives no confidence interval is clear: This measured value of $\widehat{\alpha}$ would be unlikely *no matter what the true value of* α *was.*

There are several *ad hoc* ways to set confidence limits in such cases, although many frequentists would prefer to stop with the weighted average of unbiased results—if the outcome is exceedingly unlikely, one should look to the experiment, not to the statistics. The methods we list below all involve placing c_1 on the physical boundary, which in our example is at $\alpha = 0$.

1. If $\widehat{\alpha}_{\mathrm{exp}} > \gamma_1(0,\varepsilon)$, as in Experiment A, c_2 is defined. Use it for the upper limit, whether or not $\widehat{\alpha}_{\mathrm{exp}} > 0$.
2. If $\widehat{\alpha}_{\mathrm{exp}} < 0$, as in Experiment B, use the c_2 corresponding to $\widehat{\alpha}_{\mathrm{exp}} = 0$.
3. If c_1 is not defined, "lift up" $\widehat{\alpha}$ to $\gamma_2(0,\varepsilon)$, where $c_1 = 0$. Use the corresponding c_2 as the upper limit.

These three options are shown in in Fig. 17.5; note that there are regions where more than one of them can be used, with different results. The third option is certainly the most conservative. For Gaussian $f(\widehat{\alpha};\alpha)$ the upper limit c_2 is a one-sided Gaussian confidence limit; read the tables for a 90% two-sided limit to obtain 95% one-sided limit. Alternatively, read the intercepts of the dotted lines in Fig. 17.7. (The horizontal axis is incorrectly labeled for this application.)

2. The Bayesian approach [3]. This is the approach favored in the older literature, and has (unfortunately and incorrectly) been referred to as the "PDG method" in certain papers. To begin with, it is argued that while α is not a statistical variable, our *knowledge* of α is less than complete, and it is fair to describe our uncertainty by treating α as a statistical variable. The parameterized p.d.f. $f(\widehat{\alpha};\alpha)$ is replaced by the conditional p.d.f. $f(\widehat{\alpha}|\alpha)$. The confidence limit question can then be rephrased: Our measurements provide $f(\widehat{\alpha}|\alpha)$, that is, information about $\widehat{\alpha}$ for a fixed and unknown value of α, while we really want to know $g(\alpha|\widehat{\alpha})$, which tells us that, given our measurement $\widehat{\alpha}$, the "true answer" α lies between α and $\alpha + d\alpha$ with probability $g(\alpha|\widehat{\alpha})\,d\alpha$. The connection is provided by Bayes' theorem (Eq. (16.7):

$$g(\alpha|\widehat{\alpha}) = \frac{f(\widehat{\alpha}|\alpha)\,\pi(\alpha)}{\int f(\widehat{\alpha}|\alpha)\,\pi(\alpha)\,d\alpha}\,. \tag{17.33}$$

Here $\pi(\alpha)$ represents our "advance knowledge" of the value of α. In the usual case we claim no prior knowledge, so that before the experiment all physically reasonable values of α are equally probable: $\pi(\alpha)$ is a constant over the region of interest and zero in the unphysical region. This assumption leads to the conclusion that

$$g(\alpha|\widehat{\alpha}) = \begin{cases} f(\widehat{\alpha}|\alpha)/\int f(\widehat{\alpha}|\alpha)\,d\alpha & \text{if } \alpha \text{ is in the physical region;} \\ 0 & \text{otherwise;} \end{cases} \tag{17.34}$$

where this time the integral is over the physical region. In Fig. 17.6 we assume that an ensemble of experiments would produce values for $\widehat{\alpha}$ which distribute as shown, with a significant probability of obtaining

results with unphysical values. With our assumed step function $\pi(\alpha)$, the effect of Eq. (17.33) or (17.34) is to replace this distribution with the function shown by the shaded region, except that it is renormalized to unit area. By stating our confidence at the 90% level that α lies below the beginning of the dark shaded region, we mean that 90% of the area in the physical region is in the light shaded region.

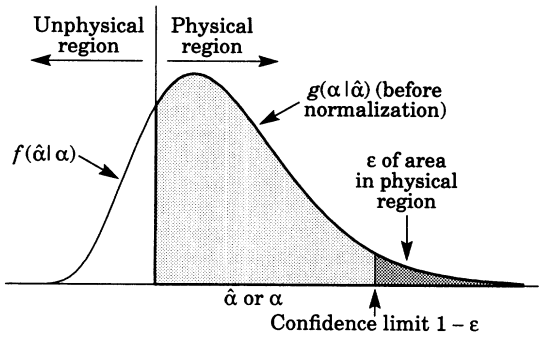

Figure 17.6: An example of a bounded physical region, in which a measurement $\hat{\alpha}$ can fall in an unphysical region with significant probability. If we assume that α, the quantity we are trying to measure, cannot lie in the unphysical region (0 probability) but can lie anywhere in the physical region ("no prior knowledge"), then Bayes' theorem says that our new knowledge of the distribution of α, given our measurement $\hat{\alpha}$, is given by the shaded function after appropriate renormalization.

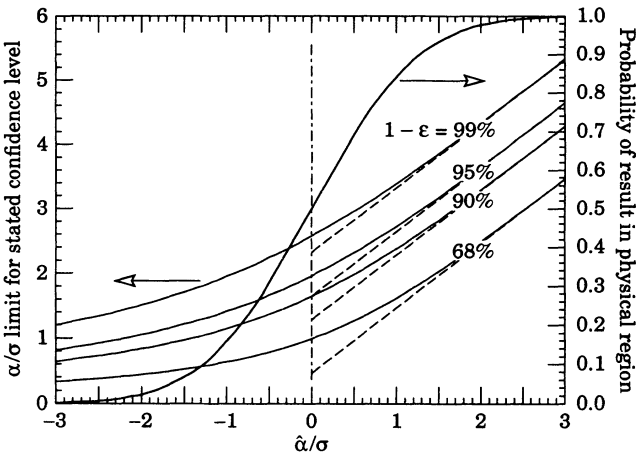

Figure 17.7: Application of the Bayesian scheme shown in Fig. 17.6 to the case of Gaussian $f(\hat{\alpha}|\alpha)$. For example, if our measurement $\hat{\alpha}$ is 1.0 standard deviations negative, then we conclude that $\alpha < 1.15\sigma$ with 90% probability—however, there is only a 31% probability that an experimental result as low as this would occur. Note that these are upper limits, so that the asymptote for large $\hat{\alpha}/\sigma$ corresponds to a one-sided confidence interval, *e.g.*, the asymptote for a 95% confidence level is $\alpha < \hat{\alpha} + 1.64\sigma$, corresponding to a 90% confidence interval for a two-sided distribution. The dashed lines show the frequentist limit; if Option 3 is used, these are extended horizontally to the right for negative $\hat{\alpha}/\sigma$.

In most cases of interest in this Review, $\hat{\alpha}$ is assumed to be a random value from a Gaussian distribution. Application of the procedure sketched in Fig. 17.6 then leads to the family of curves shown in Fig. 17.7. The confidence limit set by this method is always greater than the [one-sided] confidence interval set without the restriction of an unphysical region, and approaches it from above as the tail in the unphysical region becomes unimportant. It is also greater than any of the limits shown in Fig. 17.5. With a small modification (exclusion of that portion of the negative tail inside the physical region in the confidence interval definition), it smoothly approaches the usual two-sided confidence interval for Gaussian distributions.

Even so, it is not a valid confidence limit. If it were, the interval would include the true value of α with *exactly* $1-\varepsilon$ probability no matter what the true value was. If the true answer is zero, our procedure, by guaranteeing a limit greater than zero for any experiment, also guarantees that the confidence interval for any ε includes $\alpha_{\rm actual}$ with 100% probability. Only as α increases does the probability decrease toward the α-independent Gaussian result.

The error function corresponding to the right axis of Fig. 17.7 shows the probability that $\hat{\alpha}/\sigma$ at or below the given value should occur. If the experimental value is exceeding improbable, then the formal confidence limit obtained by this or any other method means very little.

What about the arbitrariness of $\pi(\alpha)$? If the square of the neutrino mass is measured ($\alpha = m_\nu^2$), then should we not take the prior knowledge distribution as proportional to $\sqrt{\alpha}$?[†] There are other attractive options. Jeffreys points out that if $\pi(\alpha)\,d\alpha = d\alpha/\alpha$, then the distributions for α and α^n are proportional [16], but there are practical difficulties with this approach. Lynch has investigated prior distributions that are constant in α, α^2, and $\sqrt{\alpha}$ in the context of Gaussian $f(\hat{\alpha}|\alpha)$, and has observed that assuming a prior distribution that is flat in α gives results that are much more satisfactory than one gets from the others [17]: All three methods have the property that the probability that the calculated limit contains the correct answer is 100% when $\alpha = 0$ and approaches the proper value when $\alpha >> \sigma$, but the approach to the proper value as α increases is much faster when the prior distribution is taken to be flat in α. In this case the approach is also monotonic, giving it the "conservative" property that for no value of α will the method produce a limit that has a probability of being correct that is less than the stated confidence limit. Although there is nothing unique about the limit calculated with a constant $\pi(\alpha)$, it has desirable features and no obvious replacement.

Summary: If there is a significant probability of obtaining an estimator corresponding to an unphysical value for a parameter, there is no universally accepted way way to make a statement of the sort "α is less that c_2 with probability $1-\varepsilon$." A variety of upper limits can be defined, but no method is entirely satisfactory. The Bayesian method with a flat prior distribution gives a reasonable upper limit which combines everything we know about the unknown quantity α into a physically reasonable value, but it does not give a complete summary of the information contained in the experiment.

17.5.4. *Poisson processes with background* [18] :

If we observe n_0 events in a Poisson process which has two components, signal and background, estimating a limit on the signal is more complicated. Let μ_S be the unknown mean (the Poisson parameter) for the signal and μ_B be the mean for the sum of all backgrounds. Assume μ_B is known with negligible error; however we don't know n_B, the actual number of events resulting from the background. We do know that $n_B \le n_0$. If $\mu_B + \mu_S$ is large, the Gaussian approximation to the Poisson distribution (see Sec. 16.3.2) is usually adequate, and one can define confidence intervals or limits as above, assuming $\hat{n}_B \approx \mu_B$ and therefore $\hat{\mu}_S = n_0 - \mu_B$ with variance equal to n_0 (larger than $\hat{\mu}_S$ to allow for the error in $\hat{n}_B$).

Otherwise an upper limit can be defined by extension of the argument of the preceding section. Let N be the desired upper limit on μ_S with confidence coefficient ε. Set N to be that value of μ_S such that any random repeat of the current experiment with $\mu_S = N$ and the same μ_B would observe *more* than n_0 events in total *and* would have $n_B \le n_0$, all with probability $1-\varepsilon$. For any assumed N and μ_B we can calculate this probability:

$$1-\varepsilon = 1 - \frac{e^{-(\mu_B+N)} \sum_{n=0}^{n_0} \frac{(\mu_B+N)^n}{n!}}{e^{-\mu_B} \sum_{n=0}^{n_0} \frac{\mu_B^n}{n!}} \,. \qquad (17.35)$$

We adjust N to obtain a desired ε. For $\mu_B = 0$ this converges to Eq. (17.32). As in that case (see the last paragraph of Section 17.5.2) this gives a *conservative* upper limit in that for any given true μ_S we get a true probability $\geq 1 - \varepsilon$ that $N \geq \mu_S$, averaged over a large set of identically performed experiments. For $\varepsilon = 0.10$, Fig. 17.8 shows N as a function of n_0 and μ_B.

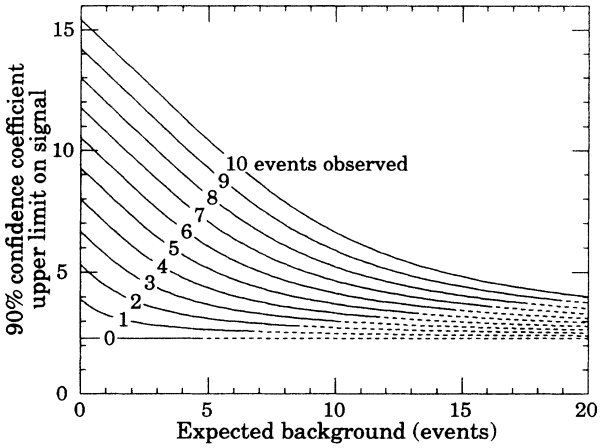

Figure 17.8: 90% confidence coefficient upper limit on the number of signal events as a function of the expected number of background events. For example, if the expected background is 8 events and 5 events are observed, then the signal is 4.0 (approximately) or less with 90% confidence. Dashed portions indicate regions where it is to be expected that the number observed would exceed the number actually observed $\geq 99\%$ of the time, even in the complete absence of signal.

Averaging of experiments and other comparisons require that n_0 and μ_B be quoted and the technique used for upper limit extraction be given.

If $\mu_B \gg n_0$ the experimenter should question the probability of observing n_B as that n_0. If this is very small the background, μ_B, may not have been calculated properly and the upper limit for μ_S obtained under those assumptions may be too low. For example, in Fig. 17.8, the dashed portions of the curves lie in the region where n_0 is expected to exceed the observed value 99% of the time (or more), even in the complete absence of signal. In these regions one should be cautious about accepting the results of the measurement.

As in the Gaussian case (Sec. 17.5.3), whenever $n_0 < \mu_B$ some experimenters may prefer to use N calculated as if $n_0 \approx \mu_B$ rather than the smaller value obtained from the observed n_0.

17.6. Propagation of errors

Suppose we have a set of N random variables y_i which may be direct measurements or derived estimators $\widehat{\alpha}$, and we have a covariance matrix $V(y)$ for these. We can make a transformation to a different set of variables $f_n \equiv f_n(y)$, $j = 1, \ldots, M$ $(M \leq N)$ and obtain best estimates for the f_n from

$$\widehat{f}_n \approx f_n(\widehat{y}) + \frac{1}{2}\sum_{k,n}^{N} V_{kn}(\widehat{y}) \left[\frac{\partial^2 f_n}{\partial y_k \, \partial y_n}\right]_{\widehat{y}} \tag{17.36}$$

with covariance matrix

$$V_{ij}(\widehat{f}) \approx \sum_{n,m} \left.\frac{\partial f_i}{\partial y_n}\right|_{\widehat{y}} \left.\frac{\partial f_n}{\partial y_m}\right|_{\widehat{y}} V_{nm}(\widehat{y}) \, . \tag{17.37}$$

For a single-valued function f of a single measurement y with variance σ^2 (*i.e.*, $M = 1, N = 1$), this becomes

$$\begin{aligned} \widehat{f} &\approx f(\widehat{y}) + \frac{1}{2}\sigma^2 f''(\widehat{y}) \\ V(\widehat{f}) &\approx \sigma^2 [f'(\widehat{y})]^2 \, , \end{aligned} \tag{17.38}$$

where the primes denote differentiation with respect to y, evaluated at $\widehat{y}$.

These approximations are based on a Taylor expansion of f about the true value of y. If f is approximately linear in y over a range of roughly $\widehat{y}_i \pm \sigma(y_i)$, the approximation is good and the second-order terms in (17.36) and (17.38) can be neglected. This is what is usually done. However, if linearity is badly violated (*e.g.*, $f \propto 1/y$ and $\widehat{y}$ is no more than a few σ from zero), it should be recognized that propagation of errors will give very approximate results. In such cases $\widehat{f} \approx f(\widehat{y})$ may be a biased estimator for f even if $\widehat{y}$ is unbiased for y, and the second-order terms in (17.36) and (17.38) will help to reduce that bias.

*In addition to the references cited, communications with R.D. Cousins, F. James, G. Lynch, and B. Roe have been invaluable in formulating this section.

†There is an additional problem: Even if we set a confidence limit on m_ν^2 by some particular recipe, it translates into a different confidence limit on $\sqrt{m_\nu^2}$ except when a Bayesian procedure with Jeffreys' $\pi(\alpha) \propto 1/\alpha$ prior distribution is used.

18. MONTE CARLO TECHNIQUES

Revised June 1994 with the help of T. Adye, O. Dahl, and H.-J. Trost.

Monte Carlo techniques are used to simulate on a computer random behavior which is too complex to be derived analytically. Most calculations are based upon pseudorandom numbers, a reproducible sequence of numbers generated on the open interval (0,1) in such a way that they satisfy various statistical tests for a uniform distribution, with independent numbers. (Caution: some commercial random number generators fill the closed interval [0,1]. The occurrence of 0 or 1 can sometimes cause problems for the algorithms below). No such numbers are truly uniform and independent. Many commercial random number generators sacrifice randomness in favor of speed. It is not rare that unforeseen correlations will introduce non-negligible errors in the results. A useful test for this is to recompute the same results with a different algorithm for the pseudorandom numbers. To improve the performance of an existing generator one may use the Bays-Durham algorithm [see Ref. 1 for discussion]: (a) Initialize by generating and storing N (*e.g.*, $N = 97$) random numbers in an array v, using the available generator. Generate a new random number u and save it. (b) On the next call, use this u as an address $j = 1+$ (integer part of Nu) to select v_j as the random number to be returned. Also save this v_j as u for the next call. Replace v_j in the array with a new random number using the available generator. On the next call, go to (b).

A second problem sometimes encountered in computations requiring long sequences of random numbers is that all pseudorandom number generators will eventually begin over and repeat the same sequence. One may choose algorithms which minimize the number used. One may also use two or three different generators in different parts of the program.

Monte Carlo simulations of complex processes break them down into a sequence of steps. At each step a particular outcome is chosen from a set of possibilities according to a certain p.d.f. To do this we must transform our uniform random numbers into random numbers sampled from different distributions on different ranges.

Two techniques are in wide use to do this. We will discuss only single variable cases; multiple variable cases use straightforward extensions of these techniques. We assume we are in possession of a random number u chosen from a uniform distribution on (0,1).

18.1. Inverse transform method

If the desired probability density function is $f(x)$ on the range $-\infty < x < \infty$, its cumulative distribution function (expressing the probability that $x \leq a$) is given by Eq. (16.1). If a is chosen with probability density $f(a)$, then the integrated probability up to point a, $F(a)$, is itself a random variable which will occur with uniform probability density on $[0, 1]$. If x can take on any value, and ignoring the endpoints, we can then find a unique x chosen from the p.d.f. $f(s)$ for a given u if we set

$$u = F(x) \ , \tag{18.1}$$

provided we can find an inverse of F, defined by

$$x = F^{-1}(u) \ . \tag{18.2}$$

This method is shown in Fig. 18.1a.

For a discrete distribution, $F(x)$ will have a discontinuous jump of size $f(x_k)$ at each allowed $x_k, k = 1, 2, \cdots$. Choose u from a uniform distribution on (0,1) as before. Find x_k such that

$$F(x_{k-1}) < u \leq F(x_k) \equiv \text{Prob}\,(x \leq x_k) = \sum_{i=1}^{k} f(x_i) \ ; \tag{18.3}$$

then x_k is the value we seek (note: $F(x_0) \equiv 0$). This algorithm is illustrated in Fig. 18.1b.

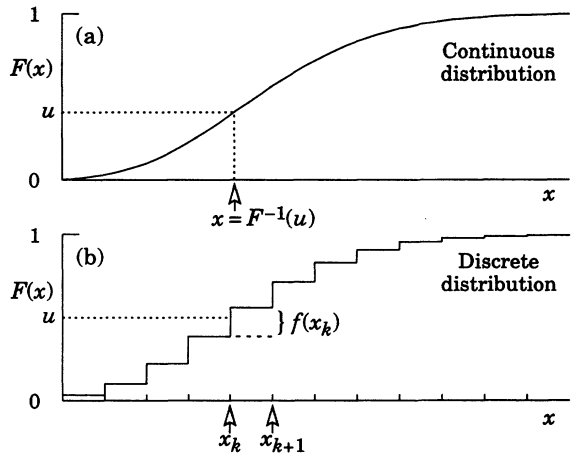

Figure 18.1: Use of a random number u chosen from a uniform distribution (0,1) to find a random number x from a distribution with cumulative distribution function $F(x)$.

18.2. Acceptance-rejection method (Von Neumann)

Very commonly an analytic form for $F(x)$ is unknown or too complex to work with, so that obtaining an inverse as in Eq. (18.2) is impractical. We suppose that for any given value of x the probability density function $f(x)$ can be computed and further that enough is known about $f(x)$ that we can enclose it entirely inside a shape which is C times an easily generated distribution $h(x)$ as illustrated in Fig. 18.2.

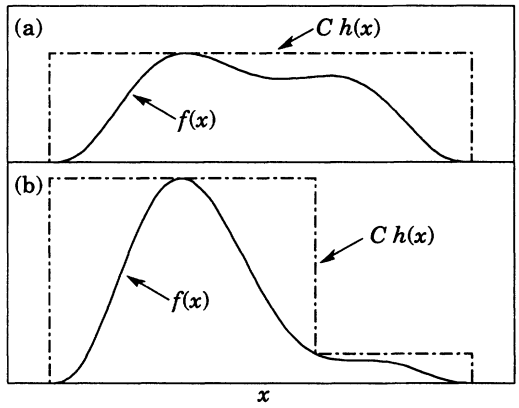

Figure 18.2: Illustration of the acceptance-rejection method. Random points are chosen inside the upper bounding figure, and rejected if the ordinate exceeds $f(x)$. Lower figure illustrates importance sampling.

Frequently $h(x)$ is uniform or is a normalized sum of uniform distributions. Note that both $f(x)$ and $h(x)$ must be normalized to unit area and therefore the proportionality constant $C > 1$. To generate $f(x)$, first generate a candidate x according to $h(x)$. Calculate $f(x)$ and the height of the envelope $C\,h(x)$; generate u and test if $uC\,h(x) \leq f(x)$. If so, accept x; if not reject x and try again. If we regard x and $uC\,h(x)$ as the abscissa and ordinate of a point in a two-dimensional plot, these points will populate the entire area $C\,h(x)$ in a smooth manner; then we accept those which fall under $f(x)$. The efficiency is the ratio of areas, which must equal $1/C$; therefore we must keep C as close as possible to 1.0. Therefore we try to choose $C\,h(x)$ to be as close to $f(x)$ as convenience dictates, as in the lower part of Fig. 18.2. This practice is called importance sampling, because

we generate more trial values of x in the region where $f(x)$ is most important.

18.3. Algorithms

Algorithms for generating random numbers belonging to many different distributions are given by Press [1], Ahrens and Dieter [2], Rubinstein [3], Everett and Cashwell [4], Devroye [5], and Walck [6]. For many distributions alternative algorithms exist, varying in complexity, speed, and accuracy. For time-critical applications, these algorithms may be coded in-line to remove the significant overhead often encountered in making function calls. Variables named "u" are assumed to be independent and uniform on (0,1).

In the examples given below, we use the notation for the variables and parameters given in Table 16.1.

18.3.1. *Sine and cosine of random angle*:

Generate u_1 and u_2. Then $v_1 = 2u_1 - 1$ is uniform on $(-1,1)$, and $v_2 = u_2$ is uniform on (0,1). Calculate $r^2 = v_1^2 + v_2^2$. If $r^2 > 1$, start over. Otherwise, the sine (S) and cosine (C) of a random angle are given by

$$S = 2v_1v_2/r^2 \quad \text{and} \quad C = (v_1^2 - v_2^2)/r^2 \ . \tag{18.4}$$

18.3.2. *Gaussian distribution*:

If u_1 and u_2 are uniform on (0,1), then

$$z_1 = \sin 2\pi u_1 \sqrt{-2\ln u_2} \quad \text{and} \quad z_2 = \cos 2\pi u_1 \sqrt{-2\ln u_2} \tag{18.5}$$

are independent and Gaussian distributed with mean 0 and $\sigma = 1$.

There are many faster variants of this basic algorithm. For example, construct $v_1 = 2u_1 - 1$ and $v_2 = 2u_2 - 1$, which are uniform on $(-1,1)$. Calculate $r^2 = v_1^2 + v_2^2$, and if $r^2 > 1$ start over. If $r^2 < 1$, it is uniform on (0,1). Then

$$z_1 = v_1\sqrt{\frac{-2\ln r^2}{r^2}} \quad \text{and} \quad z_2 = v_2\sqrt{\frac{-2\ln r^2}{r^2}} \tag{18.6}$$

are independent numbers chosen from a normal distribution with mean 0 and variance 1. $z_i' = \mu + \sigma z_i$ distributes with mean μ and variance σ^2.

For a multivariate Gaussian, see the algorithm in Ref. 7.

18.3.3. $\chi^2(n)$ distribution:

For n even, generate $n/2$ uniform numbers u_i; then

$$y = -2\ln\left(\prod_{i=1}^{n/2} u_i\right) \quad \text{is} \quad \chi^2(n) \ . \tag{18.7}$$

For n odd, generate $(n-1)/2$ uniform numbers u_i and one Gaussian z as in Sec. 18.3.2; then

$$y = -2\ln\left(\prod_{i=1}^{(n-1)/2} u_i\right) + z^2 \quad \text{is} \quad \chi^2(n) \ . \tag{18.8}$$

For $n \gtrsim 30$ the much faster Gaussian approximation for the χ^2 may be preferable: generate z as in Sec. 18.3.2 and use $y = \left[z + \sqrt{2n-1}\right]^2/2$; if $z < -\sqrt{2n-1}$ reject and start over.

18.3.4. *Gamma distribution*:

All of the following algorithms are given for $\lambda = 1$. For $\lambda \neq 1$, divide the resulting random number x by λ.

- If $k = 1$ (the *exponential* distribution), accept $x = -(\ln u)$.
- If $0 < k < 1$, initialize with $v_1 = (e + k)/e$ (with $e = 2.71828...$ being the natural log base). Generate u_1, u_2. Define $v_2 = v_1u_1$.

  Case 1: $v_2 \leq 1$. Define $x = v_2^{1/k}$. If $u_2 \leq e^{-x}$, accept x and stop, else restart by generating new u_1, u_2.
  Case 2: $v_2 > 1$. Define $x = -\ln([v_1 - v_2]/k)$. If $u_2 \leq x^{k-1}$, accept x and stop, else restart by generating new u_1, u_2. Note that, for $k < 1$, the probability density has a pole at $x = 0$, so that return values of zero due to underflow must be accepted or otherwise dealt with.
- Otherwise, if $k > 1$, initialize with $c = 3k - 0.75$. Generate u_1 and compute $v_1 = u_1(1 - u_1)$ and $v_2 = (u_1 - 0.5)\sqrt{c/v_1}$. If $x = k + v_2 - 1 \leq 0$, go back and generate new u_1; otherwise generate u_2 and compute $v_3 = 64v_1^3u_2^2$. If $v_3 \leq 1 - 2v_2^2/x$ **or** if $\ln v_3 \leq 2\{[k-1]\ln[x/(k-1)] - v_2\}$, accept x and stop; otherwise go back and generate new u_1.

18.3.5. *Binomial distribution*:

If $p \leq 1/2$, iterate until a successful choice is made: begin with $k = 1$; compute $P_k = q^n$ [for $k \neq 1$ use $P_k \equiv f(r_k; n, p)$, and store P_k into B; generate u. If $u \leq B$ accept $r_k = k - 1$ and stop; otherwise increment k by 1 and compute next P_k and add to B; generate a new u and repeat. If we arrive at $k = n + 1$, stop and accept $r_{n+1} = n$. If $p > 1/2$ it will be more efficient to generate r from $f(r; n, q)$, *i.e.*, with p and q interchanged, and then set $r_k = n - r$.

18.3.6. *Poisson distribution*:

Iterate until a successful choice is made: Begin with $k = 1$ and set $A = 1$ to start. Generate u. Replace A with uA; if now $A < \exp(-\mu)$, where μ is the Poisson parameter, accept $n_k = k - 1$ and stop. Otherwise increment k by 1, generate a new u and repeat, always starting with the value of A left from the previous try. For large $\mu(\gtrsim 10)$ it may be satisfactory (and much faster) to approximate the Poisson distribution by a Gaussian distribution (see our Probability chapter, Sec. 16.3.3) and generate z from $f(z;0,1)$; then accept $x = \max(0, [\mu + z\sqrt{\mu} + 0.5])$ where [ ] signifies the greatest integer $\leq$ the expression.

18.3.7. *Student's t* distribution:

For $n > 0$ degrees of freedom (n not necessarily integer), generate x from a Gaussian with mean 0 and $\sigma^2 = 1$ according to the method of 18.3.2. Next generate y, an independent gamma random variate with $k = n/2$ degrees of freedom. Then $z = x\sqrt{2n}/\sqrt{y}$ is distributed as a t with n degrees of freedom.

For the special case $n = 1$, the Breit-Wigner distribution, generate u_1 and u_2; set $v_1 = 2u_1 - 1$ and $v_2 = 2u_2 - 1$. If $v_1^2 + v_2^2 \leq 1$ accept $z = v_1/v_2$ as a Breit-Wigner distribution with unit area, center at 0.0, and FWHM 2.0. Otherwise start over. For center M_0 and FWHM Γ, use $W = z\Gamma/2 + M_0$.

19.1. Impedances (SI units)

ρ = resistivity at room temperature in $10^{-8}\,\Omega$ m:
~ 1.7 for Cu ~ 5.5 for W
~ 2.4 for Au ~ 73 for SS 304
~ 2.8 for Al ~ 100 for Nichrome
(Al alloys may have double the Al value.)

For alternating currents, instantaneous current I, voltage V, angular frequency ω:

$$V = V_0\, e^{j\omega t} = ZI\ . \tag{19.1}$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance C: $Z = 1/j\omega C$.

Impedance of free space: $Z = \sqrt{\mu_0/\epsilon_0} = 376.7\ \Omega$.

Impedance per unit length of a flat conductor of width w (high frequency, ν):

$$Z = \frac{(1+j)\,\rho}{w\,\delta}\ , \quad \text{where } \delta = \text{effective skin depth}\ ; \tag{19.2}$$

$$\delta = \sqrt{\frac{\rho}{\pi\nu\mu}} \approx \frac{6.6\text{ cm}}{\sqrt{\nu\,(\text{Hz})}} \quad \text{for Cu}\ . \tag{19.3}$$

19.2. Capacitance $\widehat{C}$ and inductance $\widehat{L}$ per unit length (SI units)

Flat rectangular plates of width w, separated by $d \ll w$:

$$\widehat{C} = \epsilon\,\frac{w}{d}\ ; \qquad \widehat{L} = \mu\,\frac{d}{w}\ ; \tag{19.4}$$

$$\frac{\epsilon}{\epsilon_0} = 2 \text{ to } 6 \text{ for plastics; } 4 \text{ to } 8 \text{ for porcelain, glasses.} \tag{19.5}$$

Coaxial cable of inner radius r_1, outer radius r_2:

$$\widehat{C} = \frac{2\pi\,\epsilon}{\ln\,(r_2/r_1)}\ ; \quad \widehat{L} = \frac{\mu}{2\pi}\,\ln\,(r_2/r_1)\ . \tag{19.6}$$

Transmission lines (no loss):

$$\text{Impedance: } Z = \sqrt{\widehat{L}/\widehat{C}}\ . \tag{19.7}$$

$$\text{Velocity: } v = 1/\sqrt{\widehat{L}\,\widehat{C}} = 1/\sqrt{\mu\epsilon}\ . \tag{19.8}$$

19.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v = \beta c$, and energy $E = \gamma mc^2$, traveling in a circular orbit of radius R, the energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3}\,\frac{e^2}{R}\,\beta^3\,\gamma^4\ . \tag{19.9}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E\ (\text{in MeV}) \approx 0.0885\ [E(\text{in GeV})]^4/R(\text{in m})\ . \tag{19.10}$$

For $\gamma \gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9}\alpha\gamma\,F(\omega/\omega_c)\,d(\hbar\omega)\ , \tag{19.11}$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{19.12}$$

is the critical frequency. The normalized function $F(y)$ is

$$F(y) = \frac{9}{8\pi}\sqrt{3}\,y\int_y^\infty K_{5/3}\,(x)\ dx\ , \tag{19.13}$$

where $K_{5/3}\,(x)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_c\,(\text{in keV}) \approx 2.22\ [E(\text{in GeV})]^3/R(\text{in m})\ . \tag{19.14}$$

Fig. 19.1 shows $F(y)$ over the important range of y.

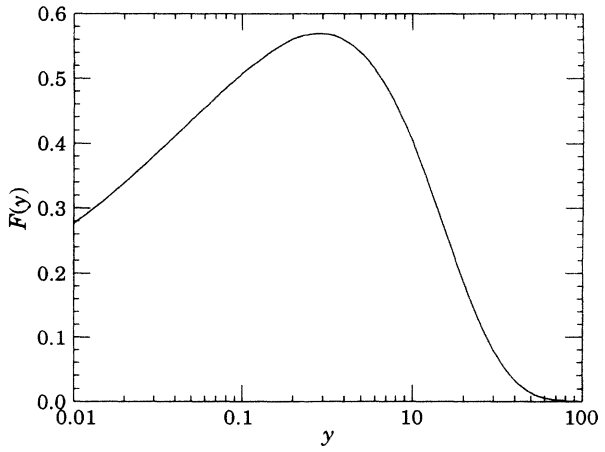

Figure 19.1: The normalized synchrotron radiation spectrum $F(y)$.

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha\,(\omega R/c)^{1/3}\ , \tag{19.15}$$

whereas for

$\gamma \gg 1$ and $\omega \gtrsim 3\omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx \sqrt{\frac{3\pi}{2}}\,\alpha\,\gamma\left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c}\left[1 + \frac{55}{72}\frac{\omega_c}{\omega} + \ldots\right]\ . \tag{19.16}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion.

See J.D. Jackson, *Classical Electrodynamics*, 2nd edition (John Wiley & Sons, New York, 1975) for more formulae and details. In his book, Jackson uses a definition of ω_c that is twice as large as the customary one given above.

20. CLEBSCH-GORDAN COEFFICIENTS, SPHERICAL HARMONICS, AND *d* FUNCTIONS

Note: A $\sqrt{\ }$ is to be understood over *every* coefficient, *e.g.*, for $-8/15$ read $-\sqrt{8/15}$.

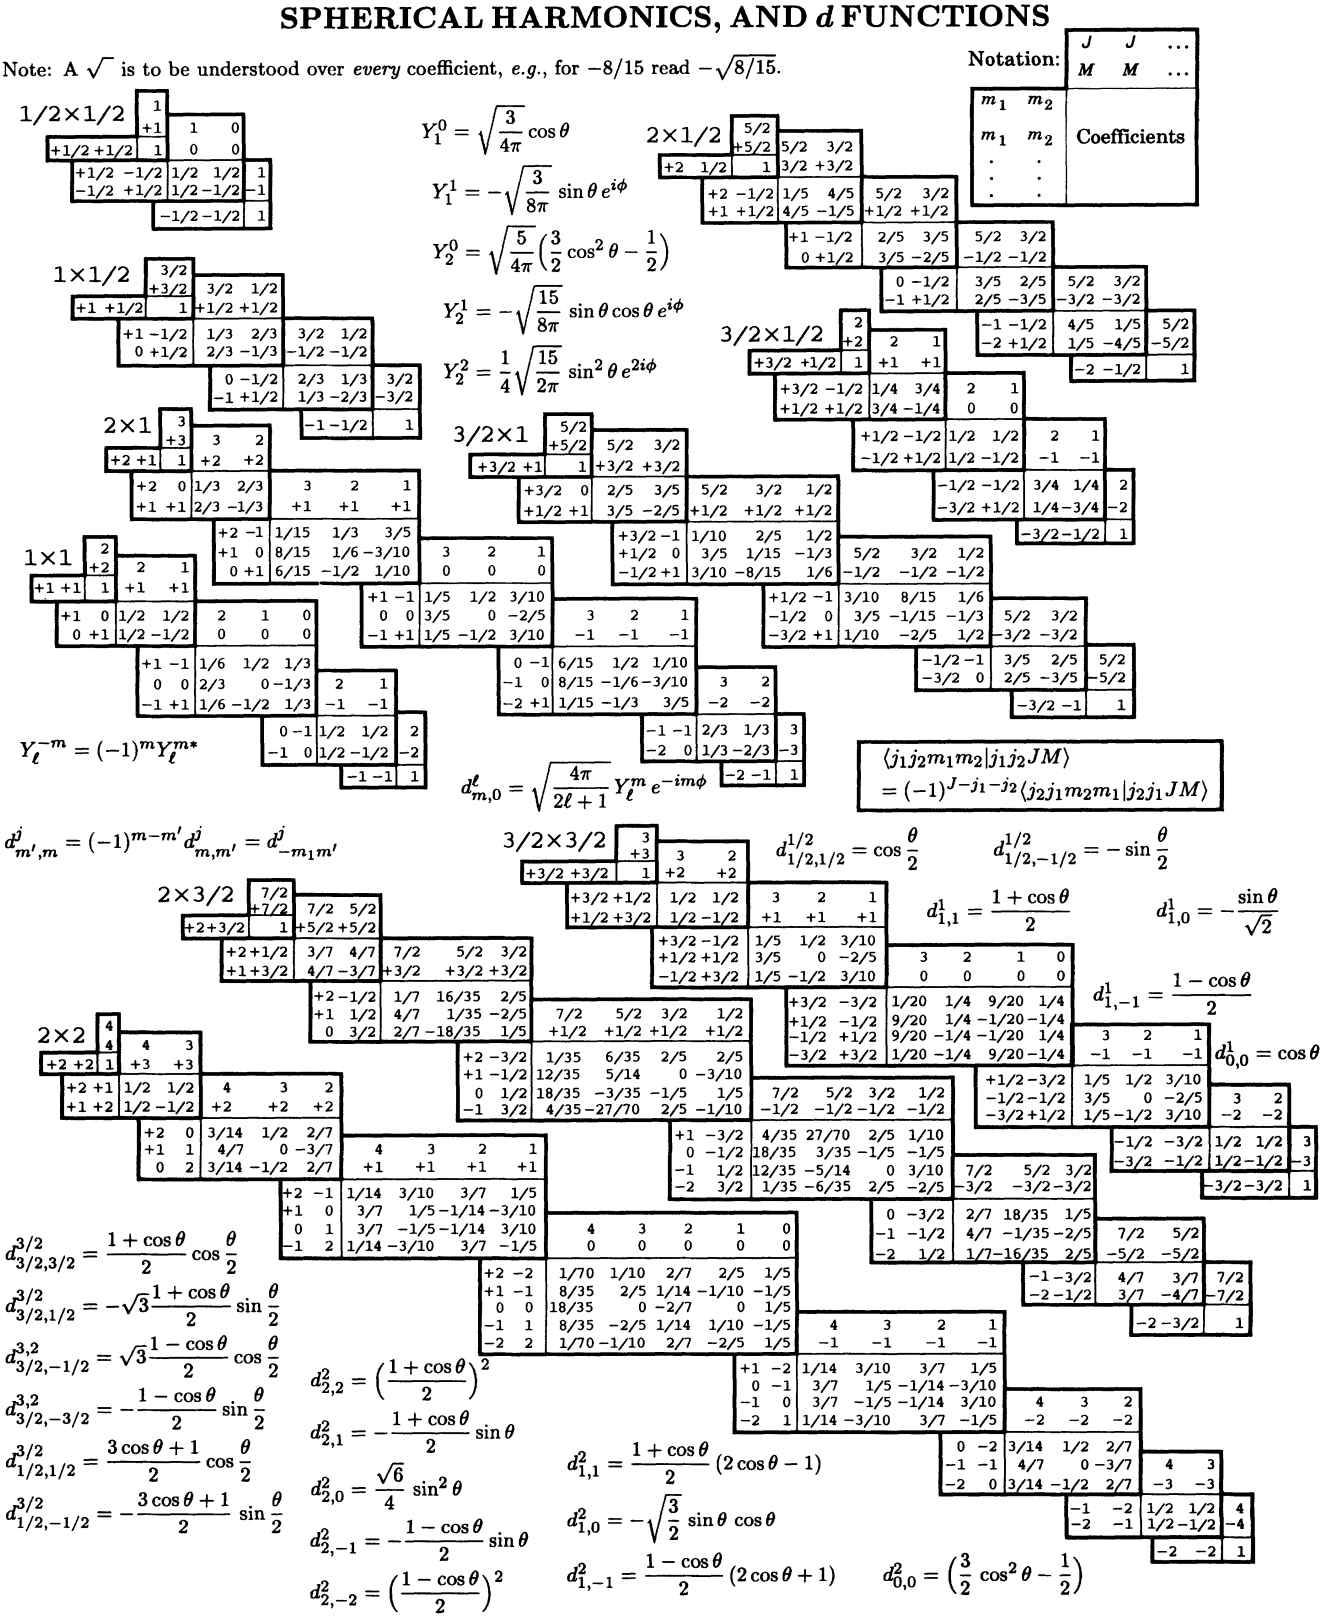

Figure 20.1: Sign convention is that of Wigner (*Group Theory*, Academic Press, New York, 1959), also used by Condon and Shortley (*The Theory of Atomic Spectra*, Cambridge Univ. Press, New York, 1953), Rose (*Elementary Theory of Angular Momentum*, Wiley, New York, 1957), and Cohen (*Tables of the Clebsch-Gordan Coefficients*, North American Rockwell Science Center, Thousand Oaks, Calif., 1974). The signs and numbers in the current tables have been calculated by computer programs written independently by Cohen and at LBL.

21. SU(3) ISOSCALAR FACTORS AND REPRESENTATION MATRICES

The most commonly used SU(3) isoscalar factors, corresponding to the singlet, octet, and decuplet content of $8 \otimes 8$ and $10 \otimes 8$, are shown at the right. The notation uses particle names to identify the coefficients, so that the pattern of relative couplings may be seen at a glance. We illustrate the use of the coefficients below. See J.J de Swart, Rev. Mod. Phys. **35**, 916 (1963) for detailed explanations and phase conventions.

A $\sqrt{\ }$ is to be understood over every integer in the matrices; the exponent 1/2 on each matrix is a reminder of this. For example, the $\Xi \to \Omega K$ element of the $10 \to 10 \otimes 8$ matrix is $-\sqrt{6}/\sqrt{24} = -1/2$.

Intramultiplet relative decay strengths may be read directly from the matrices. For example, in decuplet $\to$ octet + octet decays, the ratio of $\Omega^* \to \Xi\overline{K}$ and $\Delta \to N\pi$ partial widths is, from the $10 \to 8 \times 8$ matrix,

$$\frac{\Gamma(\Omega^* \to \Xi\overline{K})}{\Gamma(\Delta \to N\pi)} = \frac{12}{6} \times \text{(phase space factors)} . \tag{21.1}$$

Including isospin Clebsch-Gordan coefficients, we obtain, *e.g.*,

$$\frac{\Gamma(\Omega^{*-} \to \Xi^0 K^-)}{\Gamma(\Delta^+ \to p\pi^0)} = \frac{1/2}{2/3} \times \frac{12}{6} \times p.s.f. = \frac{3}{2} \times p.s.f. \tag{21.2}$$

Partial widths for $8 \to 8 \otimes 8$ involve a linear superposition of 8_1 (symmetric) and 8_2 (antisymmetric) couplings. For example,

$$\Gamma(\Xi^* \to \Xi\pi) \sim \left(-\sqrt{\frac{9}{20}}\, g_1 + \sqrt{\frac{3}{12}}\, g_2\right)^2 . \tag{21.3}$$

The relations between g_1 and g_2 (with de Swart's normalization) and the standard D and F couplings that appear in the interaction Lagrangian,

$$\mathscr{L} = -\sqrt{2}\, D\, Tr\,(\{\overline{B}, B\}M) + \sqrt{2}\, F\, Tr\,([\overline{B}, B]\, M) , \tag{21.4}$$

where $[\overline{B}, B] \equiv \overline{B}B - B\overline{B}$ and $\{\overline{B}, B\} \equiv \overline{B}B + B\overline{B}$, are

$$D = \frac{\sqrt{30}}{40}\, g_1 , \qquad F = \frac{\sqrt{6}}{24}\, g_2 . \tag{21.5}$$

Thus, for example,

$$\Gamma(\Xi^* \to \Xi\pi) \sim (F - D)^2 \sim (1 - 2\alpha)^2 , \tag{21.6}$$

where $\alpha \equiv D/(D + F)$.

When acting upon a representation of dimension d, the generators of SU(3) transformations, λ_a $(a = 1, 8)$, are $d \times d$ matrices that obey the following commutation and anticommutation relationships:

$$[\lambda_a, \lambda_b] \equiv \lambda_a\lambda_b - \lambda_b\lambda_a = 2if_{abc}\lambda_c \tag{21.7}$$

$$\{\lambda_a, \lambda_b\} \equiv \lambda_a\lambda_b + \lambda_b\lambda_a = \frac{4}{3}\delta_{ab}I + 2d_{abc}\lambda_c , \tag{21.8}$$

where I is the $d \times d$ identity matrix, and δ_{ab} is the Kronecker delta symbol. The f_{abc} are odd under the permutation of any pair of indices, while the d_{abc} are even. The nonzero values are

$1 \to 8 \otimes 8$

$$(\Lambda) \to (N\overline{K}\ \ \Sigma\pi\ \ \Lambda\eta\ \ \Xi K) = \frac{1}{\sqrt{8}}\,(2\ \ 3\ \ -1\ \ -2)^{1/2}$$

$8_1 \to 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} N\pi & N\eta & \Sigma K & \Lambda K \\ N\overline{K} & \Sigma\pi & \Lambda\pi & \Sigma\eta\ \ \Xi K \\ N\overline{K} & \Sigma\pi & \Lambda\eta & \Xi K \\ \Sigma\overline{K} & \Lambda\overline{K} & \Xi\pi & \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{20}} \begin{pmatrix} 9 & -1 & -9 & -1 \\ -6 & 0 & 4 & 4\ \ -6 \\ 2 & -12 & -4 & -2 \\ 9 & -1 & -9 & -1 \end{pmatrix}^{1/2}$$

$8_2 \to 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} N\pi & N\eta & \Sigma K & \Lambda K \\ N\overline{K} & \Sigma\pi & \Lambda\pi & \Sigma\eta\ \ \Xi K \\ N\overline{K} & \Sigma\pi & \Lambda\eta & \Xi K \\ \Sigma\overline{K} & \Lambda\overline{K} & \Xi\pi & \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{12}} \begin{pmatrix} 3 & 3 & 3 & -3 \\ 2 & 8 & 0 & 0\ \ -2 \\ 6 & 0 & 0 & 6 \\ 3 & 3 & 3 & -3 \end{pmatrix}^{1/2}$$

$10 \to 8 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \to \begin{pmatrix} N\pi & N\eta \\ N\overline{K} & \Sigma\pi\ \ \Lambda\pi\ \ \Sigma\eta\ \ \Xi K \\ \Sigma\overline{K} & \Lambda\overline{K}\ \ \Xi\pi\ \ \Xi\eta \\ \Xi\overline{K} \end{pmatrix} = \frac{1}{\sqrt{12}} \begin{pmatrix} -6 & 6 \\ -2 & 2\ \ -3\ \ 3\ \ 2 \\ 3 & -3\ \ 3\ \ 3 \\ 12 \end{pmatrix}^{1/2}$$

$8 \to 10 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} \Delta\pi & \Sigma K \\ \Delta\overline{K} & \Sigma\pi\ \ \Sigma\eta\ \ \Xi K \\ \Sigma\pi & \Xi K \\ \Sigma\overline{K} & \Xi\pi\ \ \Xi\eta\ \ \Omega K \end{pmatrix} = \frac{1}{\sqrt{15}} \begin{pmatrix} -12 & 3 \\ 8 & -2\ \ -3\ \ 2 \\ -9 & 6 \\ 3 & -3\ \ -3\ \ 6 \end{pmatrix}^{1/2}$$

$10 \to 10 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \to \begin{pmatrix} \Delta\pi & \Delta\eta & \Sigma K \\ \Delta\overline{K} & \Sigma\pi & \Sigma\eta\ \ \Xi K \\ \Sigma\overline{K} & \Xi\pi & \Xi\eta\ \ \Omega K \\ \Xi\overline{K} & \Omega\eta \end{pmatrix} = \frac{1}{\sqrt{24}} \begin{pmatrix} 15 & 3 & -6 \\ 8 & 8 & 0\ \ -8 \\ 12 & 3 & -3\ \ -6 \\ 12 & -12 \end{pmatrix}^{1/2}$$

abc	f_{abc}

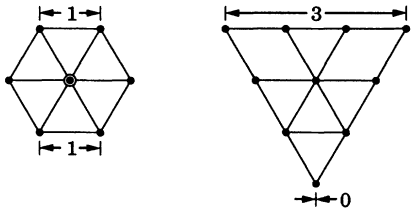
In the fundamental 3-dimensional representation, the λ_a's are

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \quad \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \quad \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

$$\lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$



22. SU(N) MULTIPLETS AND YOUNG DIAGRAMS

This note tells (1) how SU(n) particle multiplets are identified or labeled, (2) how to find the number of particles in a multiplet from its label, (3) how to draw the Young diagram for a multiplet, and (4) how to use Young diagrams to determine the overall multiplet structure of a composite system, such as a 3-quark or a meson-baryon system.

In much of the literature, the word "representation" is used where we use "multiplet," and "tableau" is used where we use "diagram."

22.1. Multiplet labels

An SU(n) multiplet is uniquely identified by a string of $(n-1)$ nonnegative integers: $(\alpha, \beta, \gamma, \ldots)$. Any such set of integers specifies a multiplet. For an SU(2) multiplet such as an isospin multiplet, the single integer α is the number of *steps* from one end of the multiplet to the other (*i.e.*, it is one fewer than the number of particles in the multiplet). In SU(3), the two integers α and β are the numbers of steps across the top and bottom levels of the multiplet diagram. Thus the labels for the SU(3) octet and decuplet

are (1,1) and (3,0). For larger n, the interpretation of the integers in terms of the geometry of the multiplets, which exist in an $(n-1)$-dimensional space, is not so readily apparent.

The label for the SU(n) singlet is $(0, 0, \ldots, 0)$. In a flavor SU(n), the n quarks together form a $(1, 0, \ldots, 0)$ multiplet, and the n antiquarks belong to a $(0, \ldots, 0, 1)$ multiplet. These two multiplets are *conjugate* to one another, which means their labels are related by $(\alpha, \beta, \ldots) \leftrightarrow (\ldots, \beta, \alpha)$.

22.2. Number of particles

The number of particles in a multiplet, $N = N(\alpha, \beta, \ldots)$, is given as follows (note the pattern of the equations).

In SU(2), $N = N(\alpha)$ is

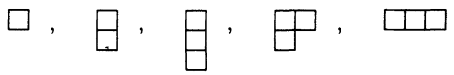
$$N = \frac{(\alpha+1)}{1} \,. \tag{22.1}$$

In SU(3), $N = N(\alpha, \beta)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \,. \tag{22.2}$$

In SU(4), $N = N(\alpha, \beta, \gamma)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\gamma+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \cdot \frac{(\beta+\gamma+2)}{2} \cdot \frac{(\alpha+\beta+\gamma+3)}{3} \,. \tag{22.3}$$



Note that there is no factor with $(\alpha+\gamma+2)$: only a *consecutive* sequence of the label integers appears in any factor. One more example should make the pattern clear for any SU(n). In SU(5), $N = N(\alpha, \beta, \gamma, \delta)$ is

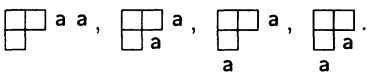
$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\gamma+1)}{1} \cdot \frac{(\delta+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \cdot \frac{(\beta+\gamma+2)}{2} \times \frac{(\gamma+\delta+2)}{2} \cdot \frac{(\alpha+\beta+\gamma+3)}{3} \cdot \frac{(\beta+\gamma+\delta+3)}{3} \cdot \frac{(\alpha+\beta+\gamma+\delta+4)}{4} \,. \tag{22.4}$$

From the symmetry of these equations, it is clear that multiplets that are conjugate to one another have the same number of particles, but so can other multiplets. For example, the SU(4) multiplets (3,0,0) and (1,1,0) each have 20 particles. Try the equations and see.

22.3. Young diagrams

A Young diagram consists of an array of boxes (or some other symbol) arranged in one or more *left-justified* rows, with each row being *at least as long* as the row beneath. The correspondence between a diagram and a multiplet label is: The top row juts out α boxes to the right past the end of the second row, the second row juts out β boxes to the right past the end of the third row, *etc.* A diagram in SU(n) has at most n rows. There can be any number of "completed" columns of n boxes buttressing the left of a diagram; these don't affect the label. Thus in SU(3) the diagrams

represent the multiplets (1,0), (0,1), (0,0), (1,1), and (3,0). In any SU(n), the quark multiplet is represented by a single box, the antiquark multiplet by a column of $(n-1)$ boxes, and a singlet by a completed column of n boxes.

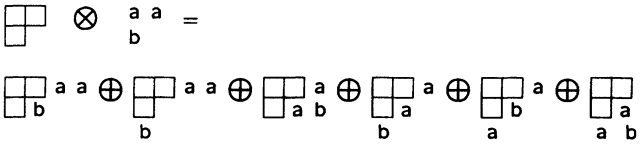


22.4. Coupling multiplets together

The following recipe tells how to find the multiplets that occur in coupling two multiplets together. To couple together more than two multiplets, first couple two, then couple a third with each of the multiplets obtained from the first two, *etc.*

First a definition: A sequence of the letters $a, b, c, \ldots$ is *admissible* if at any point in the sequence at least as many a's have occurred as b's, at least as many b's have occurred as c's, *etc.* Thus *abcd* and *aabcb* are admissible sequences and *abb* and *acb* are not. Now the recipe:

(a) Draw the Young diagrams for the two multiplets, but in one of the diagrams replace the boxes in the first row with a's, the boxes in the second row with b's, *etc.* Thus, to find the multiplets that occur in the coupling of two SU(3) octets (one might be the π-meson octet, the other the baryon octet), we draw  and . The *unlettered* diagram forms the *upper left-hand corner* of all the enlarged diagrams constructed below.



(b) Add the a's from the lettered diagram to the right-hand ends of the rows of the unlettered diagram to form all possible legitimate Young diagrams that have no more than one a per column. In general, there will be several distinct diagrams, and all the a's appear in each diagram. At this stage, the calculation of the coupling of the two SU(3) octets look as follows:

(c) Use the b's to further enlarge the diagrams already obtained, subject to the same rules. Then throw away any diagram in which the sequence of letters formed by reading *right to left* in the first row, then the second row, *etc.*, is not admissible.

(d) Proceed as in (c) with the c's (if any), *etc.*

The final result of the coupling of the two octets is:

Here only the diagrams with admissible sequences of a's and b's and with fewer than four rows (since $n = 3$) have been kept. In terms of multiplet labels, the above may be written

$$(1,1) \otimes (1,1) = (2,2) \oplus (3,0) \oplus (0,3) \oplus (1,1) \oplus (1,1) \oplus (0,0) \,.$$

In terms of numbers of particles, it may be written

$$\mathbf{8} \otimes \mathbf{8} = \mathbf{27} \oplus \mathbf{10} \oplus \overline{\mathbf{10}} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1} \,.$$

The product of the numbers on the left here is equal to the sum on the right. (See also the section on the Quark Model.)

23. KINEMATICS

Revised June 1994.

Throughout this section units are used in which $\hbar = c = 1$. The following conversions are useful: $\hbar c = 197.3$ MeV fermi, $(\hbar c)^2 = 0.3894$ (GeV)^2 mb.

23.1. Lorentz transformations

The energy E and 3-momentum $\boldsymbol{p}$ of a particle of mass m form a 4-vector $p = (E, \boldsymbol{p})$ whose square $p^2 \equiv E^2 - |\boldsymbol{p}|^2 = m^2$. The velocity of the particle is $\boldsymbol{\beta} = \boldsymbol{p}/E$. The energy and momentum $(E^*, \boldsymbol{p}^*)$ viewed from a frame moving with velocity $\boldsymbol{\beta}_f$ are given by

$$\begin{pmatrix} E^* \\ p_\parallel^* \end{pmatrix} = \begin{pmatrix} \gamma_f & -\gamma_f\beta_f \\ -\gamma_f\beta_f & \gamma_f \end{pmatrix} \begin{pmatrix} E \\ p_\parallel \end{pmatrix} , \quad p_T^* = p_T , \tag{23.1}$$

where $\gamma_f = (1-\beta_f^2)^{-1/2}$ and p_T ($p_\parallel$) are the components of $\boldsymbol{p}$ perpendicular (parallel) to $\boldsymbol{\beta}_f$. The scalar product of two 4-vectors $p_1 \cdot p_2 = E_1E_2 - \boldsymbol{p}_1 \cdot \boldsymbol{p}_2$ is invariant (frame independent).

In the collision of two particles of masses m_1 and m_2 the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$\begin{aligned} E_{\rm cm} &= \left[(E_1+E_2)^2 - (\boldsymbol{p}_1+\boldsymbol{p}_2)^2\right]^{1/2} , \\ &= \left[m_1^2 + m_2^2 + 2E_1E_2(1-\beta_1\beta_2\cos\theta)\right]^{1/2} , \end{aligned} \tag{23.2}$$

where θ is the angle between the particles. In the frame where one particle (of mass m_2) is at rest (lab frame),

$$E_{\rm cm} = (m_1^2 + m_2^2 + 2E_{1\,\rm lab}\, m_2)^{1/2} . \tag{23.3}$$

The velocity in the lab of the center-of-mass frame is

$$\boldsymbol{\beta}_{\rm cm} = \boldsymbol{p}_{\rm lab}/(E_{1\,\rm lab} + m_2) , \tag{23.4}$$

and

$$\gamma_{\rm cm} = (E_{1\,\rm lab} + m_2)/E_{\rm cm} . \tag{23.5}$$

23.2. Center of mass energy and momentum

A beam of particles with mass m and momentum $p_{\rm beam}$ is incident on a fixed target consisting of particles with mass M. The energy of the beam particles $E_{\rm beam}$, the total center-of-mass energy $E_{\rm cm}$, and center of mass momentum of one of the particles $p_{\rm cm}$ are given by

$$E_{\rm beam} = \sqrt{p_{\rm beam}^2 + m^2} \tag{23.6}$$

$$E_{\rm cm} = \sqrt{m^2 + 2E_{\rm beam}M + M^2} \tag{23.7}$$

$$p_{\rm cm} = p_{\rm beam}\frac{M}{E_{\rm cm}} . \tag{23.8}$$

For example, if a 0.80 GeV/c kaon beam is incident on a proton target, the center of mass energy is 1.699 GeV and the center of mass momentum of either particle is 0.442 GeV/c. It is also useful to note that

$$E_{\rm cm}\, dE_{\rm cm} = M\, dE_{\rm beam} = M\,\beta_{\rm beam}\, dp_{\rm beam} . \tag{23.9}$$

23.3. Lorentz-invariant amplitudes

The invariant amplitude $-i\mathscr{M}$ for a scattering or decay process is determined in perturbation theory by a set of Feynman diagrams. The convention of Bjorken and Drell is used except that fermion spinors are normalized so that $u\bar{u} = 2m$. As an example, the S-matrix for $2 \to 2$ scattering is related to $\mathscr{M}$ by

$$\begin{aligned} \langle p_1'p_2'\,|S|\,p_1p_2\rangle &= I - i(2\pi)^4\,\delta^4(p_1+p_2-p_1'-p_2') \\ &\quad \times \frac{\mathscr{M}(p_1,\,p_2;\,p_1',\,p_2')}{(2E_1)^{1/2}\,(2E_2)^{1/2}\,(2E_1')^{1/2}\,(2E_2')^{1/2}} . \end{aligned} \tag{23.10}$$

The state normalization is such that

$$\langle p'|p\rangle = (2\pi)^3\delta^3(\boldsymbol{p}-\boldsymbol{p}') . \tag{23.11}$$

23.4. Particle decays

The partial decay rate of a particle of mass M into n bodies in its rest frame is given in terms of the Lorentz-invariant matrix element $\mathscr{M}$ by

$$d\Gamma = \frac{(2\pi)^4}{2M}\,|\mathscr{M}|^2\,d\Phi_n\,(P;\,p_1,\,\ldots,\,p_n), \tag{23.12}$$

where $d\Phi_n$ is an element of n-body phase space given by

$$d\Phi_n(P;\,p_1,\,\ldots,\,p_n) = \delta^4\,(P - \sum_{i=1}^n p_i)\,\prod_{i=1}^n \frac{d^3p_i}{(2\pi)^3 2E_i} . \tag{23.13}$$

This phase space can be generated recursively, viz.

$$\begin{aligned} d\Phi_n(P;\,p_1,\,\ldots,\,p_n) &= d\Phi_j(q;\,p_1,\,\ldots,\,p_j) \\ &\quad \times\, d\Phi_{n-j+1}\,(P;\,q,\,p_{i+1},\,\ldots,\,p_n)(2\pi)^3dq^2 , \end{aligned} \tag{23.14}$$

where $q^2 = (\sum_{i=1}^j E_i)^2 - \left|\sum_{i=1}^j \boldsymbol{p}_i\right|^2$. This form is particularly useful in the case where a particle decays into another particle which subsequently decays.

23.4.1. ***Survival probability***: If a particle of mass M has mean proper lifetime τ ($= 1/\Gamma$) and has momentum $(E, \boldsymbol{p})$, then the probability that it lives for a time t_0 or greater before decaying is given by

$$P(t_0) = e^{-t_0\,\Gamma/\gamma} = e^{-Mt_0\,\Gamma/E} , \tag{23.15}$$

and the probability that it travels a distance x_0 or greater is

$$P(x_0) = e^{-Mx_0\,\Gamma/|\boldsymbol{p}|} . \tag{23.16}$$

23.4.2. ***Two-body decays***:

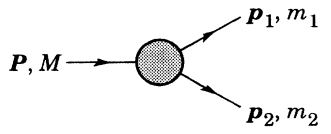


Figure 23.1: Variable definitions for two-body decays.

In the rest frame of a particle of mass M, decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M} , \tag{23.17}$$

$$\begin{aligned} |\boldsymbol{p}_1| &= |\boldsymbol{p}_2| \\ &= \frac{\left[(M^2 - (m_1+m_2)^2)\,(M^2 - (m_1-m_2)^2)\right]^{1/2}}{2M} , \end{aligned} \tag{23.18}$$

and

$$d\Gamma = \frac{1}{32\pi^2}\,|\mathscr{M}|^2\,\frac{|\boldsymbol{p}_1|}{M^2}\,d\Omega , \tag{23.19}$$

where $d\Omega = d\phi_1 d(\cos\theta_1)$ is the solid angle of particle 1.

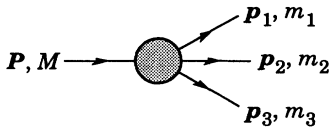

Figure 23.2: Variable definitions for three-body decays.

23.4.3. ***Three-body decays***:

Defining $p_{ij} = p_i + p_j$, $m_{ij}^2 = p_{ij}^2$, then $m_{12}^2 + m_{23}^2 + m_{13}^2 = M^2 + m_1^2 + m_2^2 + m_3^2$ and $m_{12}^2 = (P - p_3)^2 = M^2 + m_3^2 - 2ME_3$. The relative orientation of the three final-state particles is fixed if their energies are known. Their momenta can therefore be specified by giving three Euler angles (α, β, γ) which specify the orientation of the final system relative to the initial particle. Then

$$d\Gamma = \frac{1}{(2\pi)^5}\frac{1}{16M}\,|\mathscr{M}|^2\,dE_1\,dE_2\,d\alpha\,d\cos\beta\,d\gamma\,. \tag{23.20}$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5}\frac{1}{16M^2}\,|\mathscr{M}|^2\,|\boldsymbol{p}_1^*|\,|\boldsymbol{p}_3|\,dm_{12}\,d\Omega_1^*\,d\Omega_3\,, \tag{23.21}$$

where $(|\boldsymbol{p}_1^*|, \Omega_1^*)$ is the momentum of particle 1 in the rest frame of 1 and 2, and Ω_3 is the angle of particle 3 in the rest frame of the decaying particle. $|\boldsymbol{p}_1^*|$ and $|\boldsymbol{p}_3|$ are given by

$$|\boldsymbol{p}_1^*| = \frac{\left[(m_{12}^2 - (m_1+m_2)^2)\,(m_{12}^2 - (m_1-m_2)^2)\right]^{1/2}}{2m_{12}}\,, \tag{23.22a}$$

and

$$|\boldsymbol{p}_3| = \frac{\left[(M^2 - (m_{12}+m_3)^2)\,(M^2 - (m_{12}-m_3)^2)\right]^{1/2}}{2M}\,. \tag{23.22b}$$

[Compare with Eq. (23.18).]

Integrating over the angles in Eq. (23.20) (this is only possible if the decaying particle is a scalar or we average over its spin states; otherwise $\mathscr{M}$ depends on α, β, and γ) gives

$$\begin{aligned} d\Gamma &= \frac{1}{(2\pi)^3}\frac{1}{8M}\,|\mathscr{M}|^2\,dE_1\,dE_2 \\ &= \frac{1}{(2\pi)^3}\frac{1}{32M^3}\,|\mathscr{M}|^2\,dm_{12}^2\,dm_{23}^2\,. \end{aligned} \tag{23.23}$$

This is the standard form for the Dalitz plot.

23.4.3.1. *Dalitz plot:* If m_{12}^2 is fixed then the range of m_{13}^2 is determined by its values when $\boldsymbol{p}_1$ is parallel or antiparallel to $\boldsymbol{p}_3$.

$$(m_{13}^2)_{\rm max} = (E_1^* + E_3^*)^2 - \left(\sqrt{E_1^{*2} - m_1^2} - \sqrt{E_3^{*2} - m_3^2}\right)^2\,, \tag{23.24a}$$

$$(m_{13}^2)_{\rm min} = (E_1^* + E_3^*)^2 - \left(\sqrt{E_1^{*2} - m_1^2} + \sqrt{E_3^{*2} - m_3^2}\right)^2\,, \tag{23.24b}$$

where $E_3^* = (M^2 - m_{12}^2 - m_3^2)/(2m_{12})$ and $E_1^* = (m_{12}^2 + m_1^2 - m_2^2)/(2m_{12})$. The scatter plot in m_{12}^2 and m_{13}^2 has uniform phase space density [see Eq. (23.23)] and is called a Dalitz plot.

A nonuniformity in the plot gives immediate information on $|\mathscr{M}|^2$. For example, in the case of $D \to K\pi\pi$, bands appear when $m_{(K\pi)} = m_{K^*(892)}$, reflecting the appearance of the decay chain $D \to K^*(892)\pi \to K\pi\pi$.

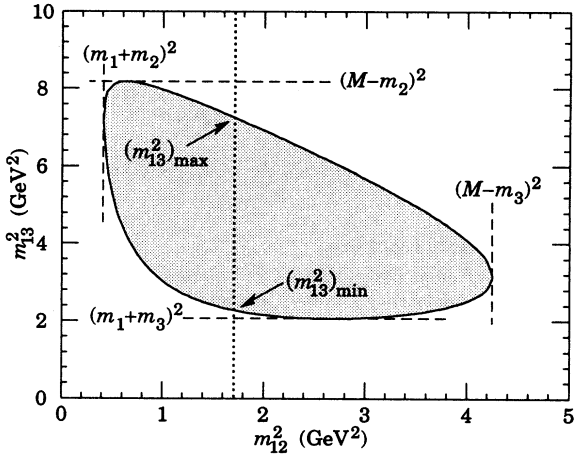

Figure 23.3: Dalitz plot for a three-body final state. In this example, the state is $\overline{K}^0\pi^+p$ at 3 GeV. Four-momentum conservation restricts events to the interior of the closed curve.

23.4.4. ***Kinematic limits***: In a three-body decay the maximum of $|\boldsymbol{p}_3|$, [given by Eq. (23.22)], is achieved when $m_{12} = m_1 + m_2$, *i.e.*, particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition, $m_3 > m_1, m_2$, then $|\boldsymbol{p}_3|_{\rm max} > |\boldsymbol{p}_1|_{\rm max}$, $|\boldsymbol{p}_2|_{\rm max}$.

23.4.5. ***Multibody decays***: The above results may be generalized to final states containing any number of particles by combining some of the particles into "effective particles" and treating the final states as 2 or 3 "effective particle" states. Thus, if $p_{ijk\ldots} = p_i + p_j + p_k + \ldots$, then

$$m_{ijk\ldots} = \sqrt{p^2_{ijk\ldots}}\,, \tag{23.25}$$

and $m_{ijk\ldots}$ may be used in place of *e.g.*, m_{12} in the relations in Sec. 23.4.3 or 23.4.3.1 above.

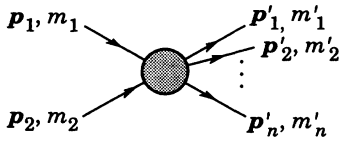

Figure 23.4: Variable definitions for production of an n-body final state.

23.5. Cross sections

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4|\mathscr{M}|^2}{4\sqrt{(p_1\cdot p_2)^2 - m_1^2m_2^2}} \times d\Phi_n(p_1+p_2;\,p_3,\ldots,p_{n+2})\,. \tag{23.26}$$

[See Eq. (23.13).] In the rest frame of m_2(lab),

$$\sqrt{(p_1\cdot p_2)^2 - m_1^2m_2^2} = m_2 p_{1\,\rm lab}\,; \tag{23.27a}$$

while in the center-of-mass frame

$$\sqrt{(p_1\cdot p_2)^2 - m_1^2m_2^2} = p_{1\rm cm}\sqrt{s}\,. \tag{23.27b}$$

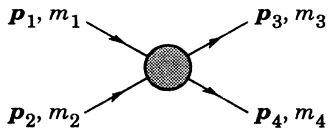

Figure 23.5: Variable definitions for a two-body final state.

23.5.1. ***Two-body reactions***:
Two particles of momenta p_1 and p_2 and masses m_1 and m_2 scatter to particles of momenta p_3 and p_4 and masses m_3 and m_4; the Lorentz-invariant Mandelstam variables are defined by

$$s = (p_1 + p_2)^2 = (p_3 + p_4)^2$$
$$= m_1^2 + 2E_1E_2 - 2\boldsymbol{p}_1 \cdot \boldsymbol{p}_2 + m_2^2 \,, \tag{23.28}$$
$$t = (p_1 - p_3)^2 = (p_2 - p_4)^2$$
$$= m_1^2 - 2E_1E_3 + 2\boldsymbol{p}_1 \cdot \boldsymbol{p}_3 + m_3^2 \,, \tag{23.29}$$
$$u = (p_1 - p_4)^2 = (p_2 - p_3)^2$$
$$= m_1^2 - 2E_1E_4 + 2\boldsymbol{p}_1 \cdot \boldsymbol{p}_4 + m_4^2 \,, \tag{23.30}$$

and they satisfy

$$s + t + u = m_1^2 + m_2^2 + m_3^2 + m_4^2 \,. \tag{23.31}$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s} \frac{1}{|\boldsymbol{p}_{1\mathrm{cm}}|^2} |\mathscr{M}|^2 \,. \tag{23.32}$$

In the center-of-mass frame

$$t = (E_{1\mathrm{cm}} - E_{3\mathrm{cm}})^2 - (p_{1\mathrm{cm}} - p_{3\mathrm{cm}})^2$$
$$-4p_{1\mathrm{cm}}\, p_{3\mathrm{cm}}\, \sin^2(\theta_{\mathrm{cm}}/2)$$
$$= t_0 - 4p_{1\mathrm{cm}}\, p_{3\mathrm{cm}}\, \sin^2(\theta_{\mathrm{cm}}/2) \,, \tag{23.33}$$

where θ_{cm} is the angle between particle 1 and 3. The limiting values t_0 ($\theta_{\mathrm{cm}} = 0$) and t_1 ($\theta_{\mathrm{cm}} = \pi$) for $2 \to 2$ scattering are

$$t_0(t_1) = \left[\frac{m_1^2 - m_3^2 - m_2^2 + m_4^2}{2\sqrt{s}}\right]^2$$
$$-\left\{\left[\left(\frac{s + m_1^2 - m_2^2}{2\sqrt{s}}\right)^2 - m_1^2\right]^{1/2}\right.$$
$$\left.\mp \left[\left(\frac{s + m_3^2 - m_4^2}{2\sqrt{s}}\right)^2 - m_3^2\right]^{1/2}\right\}^2 \,. \tag{23.34}$$

Note that t_1 is always negative. In the literature the notation t_{min} (t_{max}) for t_0 (t_1) is sometimes used. This usage should be discouraged since $t_0 > t_1$. The center-of-mass energies and momenta of the incoming particles are

$$E_{\mathrm{cm}} = \frac{s + m_1^2 - m_2^2}{2\sqrt{s}} \,, \tag{23.35}$$

$$p_{\mathrm{cm}} = \frac{\left[(s - (m_1 + m_2)^2)\,(s - (m_1 - m_2)^2)\right]^{1/2}}{2\sqrt{s}}$$
$$= \frac{p_{1\,\mathrm{lab}} m_2}{\sqrt{s}} \,, \tag{23.36}$$

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (23.2)–(23.4).]

23.5.2. ***Inclusive reactions***: Choose some direction (usually the beam direction) for the z-axis; then the energy and momentum of a particle can be written as

$$E = m_T \cosh y \,,\; p_x \,,\; p_y \,,\; p_z = m_T \sinh y \,, \tag{23.37}$$

where m_T is the transverse mass

$$m_T^2 = m^2 + p_x^2 + p_y^2 \,, \tag{23.38}$$

and the rapidity y is defined by

$$y = \frac{1}{2} \ln\left(\frac{E + p_z}{E - p_z}\right)$$
$$= \ln\left(\frac{E + p_z}{m_T}\right) = \tanh^{-1}\left(\frac{p_z}{E}\right) \,. \tag{23.39}$$

Under a boost in the z-direction to a frame with velocity β, $y \to y + \tanh^{-1}\beta$. Hence the shape of the rapidity distribution dN/dy is invariant. The invariant cross section may also be rewritten

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\, dy\, p_T dp_T} \Longrightarrow \frac{d^2\sigma}{\pi\, dy\, d(p_T^2)} \,. \tag{23.40}$$

The second form is obtained using the identity $dy/dp_z = 1/E$, and the third form represents the average over ϕ.

Feynman's x variable is given by

$$x = \frac{p_z}{p_{z\,\mathrm{max}}} \approx \frac{E + p_z}{(E + p_z)_{\mathrm{max}}} \,; \tag{23.41}$$

in the center-of-mass frame,

$$x \approx \frac{2p_{z\,\mathrm{cm}}}{\sqrt{s}} \approx \frac{2m_T \sinh y_{\mathrm{cm}}}{\sqrt{s}} \,. \tag{23.42}$$

For y_{cm} such that $e^{-2y_{\mathrm{cm}}} \ll 1$,

$$x \approx \frac{m_T}{\sqrt{s}} e^{y_{\mathrm{cm}}} \tag{23.43}$$

and

$$(y_{\mathrm{cm}})_{\mathrm{max}} = \ln\left(\sqrt{s}/m\right) \,. \tag{23.44}$$

The definition of rapidity [Eq. (23.39)] may be expanded to obtain

$$y = \frac{1}{2} \ln \frac{\cos^2(\theta/2) + m^2/4p^2 + \ldots}{\sin^2(\theta/2) + m^2/4p^2 + \ldots}$$
$$\approx -\ln \tan(\theta/2) \equiv \eta \tag{23.45}$$

if the particle has zenith angle θ. The pseudorapidity η defined by the second line is approximately equal to the rapidity y for $p \gg m$ and $\theta \gg 1/\gamma$, and in any case can be measured when the mass and momentum of the particle is unknown. From the definition one can obtain the identities

$$\sinh\eta = \cot\theta \tag{23.46}$$
$$\cosh\eta = 1/\sin\theta \tag{23.47}$$
$$\tanh\eta = \cos\theta \,. \tag{23.48}$$

23.5.3. ***Partial waves***: The amplitude in the center of mass for elastic scattering of spinless particles may be expanded in Legendre polynomials

$$f(k,\theta) = \frac{1}{k}\sum_{\ell}(2\ell+1)a_\ell P_\ell(\cos\theta)\ , \tag{23.49}$$

where k is the c.m. momentum, θ is the c.m. scattering angle, $a_\ell = (\eta_\ell e^{2i\delta_\ell} - 1)/2i$, $0 \le \eta_\ell \le 1$, and δ_ℓ is the phase shift of the ℓ^{th} partial wave. For purely elastic scattering, $\eta_\ell = 1$. The differential cross section is

$$\frac{d\sigma}{d\Omega} = |f(k,\theta)|^2\ . \tag{23.50}$$

The optical theorem states that

$$\sigma_{\rm tot} = \frac{4\pi}{k}{\rm Im}\, f(k,0)\ , \tag{23.51}$$

and the cross section in the ℓ^{th} partial wave is therefore bounded:

$$\sigma_\ell = \frac{4\pi}{k^2}(2\ell+1)|a_\ell|^2 \le \frac{4\pi(2\ell+1)}{k^2}\ . \tag{23.52}$$

The evolution with energy of partial-wave amplitude a_ℓ can be displayed as a trajectory in an Argand plot, as shown in Fig. 23.6.

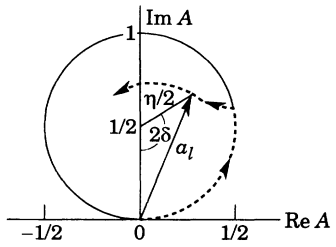

Figure 23.6: Argand plot for the display of a partial-wave amplitude as a function of energy.

The usual Lorentz-invariant matrix element $\mathscr{M}$ (see Sec. 23.3 above) for the elastic process is related to $f(k,\theta)$ by

$$\mathscr{M} = -8\pi\sqrt{s}\, f(k,\theta)\ , \tag{23.53}$$

so

$$\sigma_{\rm tot} = -\frac{1}{2k\sqrt{s}}\,{\rm Im}\,\mathscr{M}(t=0)\ , \tag{23.54}$$

where s and t are the center-of-mass energy squared and momentum transfer squared, respectively (see Sec. 23.4.1).

23.5.3.1. *Resonances:* The Breit-Wigner form for an elastic amplitude a_ℓ with a resonance at c.m. energy E_R, elastic width $\Gamma_{\rm el}$, and total width $\Gamma_{\rm tot}$ is

$$a_\ell = \frac{\Gamma_{\rm el}/2}{E_R - E - i\Gamma_{\rm tot}/2}\ , \tag{23.55}$$

where E is the c.m. energy. As shown in Fig. 23.7, in the absence of background the elastic amplitude traces a counterclockwise circle with center $ix_{\rm el}/2$ and radius $x_{\rm el}/2$, where the elasticity $x_{\rm el} = \Gamma_{\rm el}/\Gamma_{\rm tot}$. The amplitude has a pole at $E = E_R - i\Gamma_{\rm tot}/2$.

The Breit-Wigner cross section for a spin-J resonance produced in the collision of particles of spin S_1 and S_2 is

$$\sigma_{BW}(E) = \frac{(2J+1)}{(2S_1+1)(2S_2+1)}\,\frac{\pi}{k^2}\,\frac{B_{\rm in}B_{\rm out}\Gamma_{\rm tot}^2}{(E-E_R)^2+\Gamma_{\rm tot}^2/4}\ , \tag{23.56}$$

where k is the c.m. momentum, E is the c.m. energy, and $B_{\rm in}$ and $B_{\rm out}$ are the branching fractions of the resonance into the entrance and exit channels. The $2S+1$ factors are the multiplicities of the incident spin states, so they are replaced by 2 for photons, *etc.* This expression is valid only for a particle of narrow width. If the width

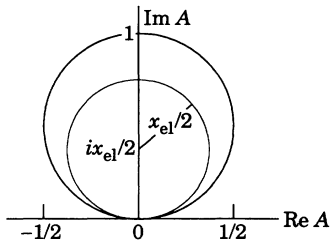

Figure 23.7: Argand plot for a resonance.

is not small, $\Gamma_{\rm tot}$ cannot be treated as a constant independent of E. There are many other forms for σ_{BW}, all of which are equivalent to the one given here in the narrow-width case. Some of these forms may be more appropriate if the resonance is broad.

The relativistic Breit-Wigner form corresponding to Eq. (23.55) is:

$$a_\ell = \frac{-m\Gamma_{\rm el}}{s - m^2 + im\Gamma_{\rm tot}}\ . \tag{23.57}$$

A better form incorporates the known kinematic dependences, replacing $m\Gamma_{\rm tot}$ by $\sqrt{s}\,\Gamma_{\rm tot}(s)$, where $\Gamma_{\rm tot}(s)$ is the width the resonance particle would have if its mass were $\sqrt{s}$, and correspondingly $m\Gamma_{\rm el}$ by $\sqrt{s}\,\Gamma_{\rm el}(s)$ where $\Gamma_{\rm el}(s)$ is the partial width in the incident channel for a mass $\sqrt{s}$:

$$a_\ell = \frac{-\sqrt{s}\,\Gamma_{\rm el}(s)}{s - m^2 + i\sqrt{s}\,\Gamma_{\rm tot}(s)}\ . \tag{23.58}$$

For the Z boson, all the decays are to particles whose masses are small enough to be ignored, so on dimensional grounds $\Gamma_{\rm tot}(s) = \sqrt{s}\,\Gamma_0/m_Z$, where Γ_0 defines the width of the Z, and $\Gamma_{\rm el}(s)/\Gamma_{\rm tot}(s)$ is constant. A full treatment of the line shape requires consideration of dynamics, not just kinematics. For the Z this is done by calculating the radiative corrections in the Standard Model.

24. CROSS-SECTION FORMULAE FOR SPECIFIC PROCESSES

24.1. Leptoproduction

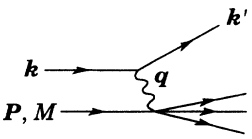

Figure 24.1: Kinematic quantities for description of lepton-nucleon scattering. k and k' are the four-momenta of incoming and outgoing leptons, P is the four-momentum of a nucleon with mass M. The exchanged particle is a γ, $W^{\pm}$, or Z^0; it transfers four-momentum $q = k - k'$ to the target.

Invariant quantities:

$\nu = \dfrac{q \cdot P}{M} = E - E'$ is the lepton's energy loss in the lab (in earlier literature sometimes $\nu = q \cdot P$). Here, E and E' are the initial and final lepton energies in the lab.

$Q^2 = -q^2 = 2(EE' - \vec{k} \cdot \vec{k}') - m_\ell^2 - m_{\ell'}^2$ where $m_\ell (m_{\ell'})$ is the initial (final) lepton mass. If $EE' \sin^2(\theta/2) \gg m_\ell^2, m_{\ell'}^2$, then

$\approx 4EE' \sin^2(\theta/2)$, where θ is the lepton's scattering angle in the lab.

$x = \dfrac{Q^2}{2M\nu}$ In the parton model, x is the fraction of the target nucleon's momentum carried by the struck quark. See section on QCD.

$y = \dfrac{q \cdot P}{k \cdot P} = \dfrac{\nu}{E}$ is the fraction of the lepton's energy lost in the lab.

$W^2 = (P+q)^2 = M^2 + 2M\nu - Q^2$ is the mass squared of the system recoiling against the lepton.

$s = (k+P)^2 = \dfrac{Q^2}{xy} + M^2$

24.1.1. ***Leptoproduction cross sections***:

$$\frac{d^2\sigma}{dx\,dy} = \nu(s - M^2)\frac{d^2\sigma}{d\nu\,dQ^2} = \frac{2\pi M\nu}{E'}\frac{d^2\sigma}{d\Omega_{\rm lab}\,dE'}$$

$$= x(s - M^2)\frac{d^2\sigma}{dx\,dQ^2}\ . \qquad (24.1)$$

24.1.2. ***Electroproduction structure functions***: The neutral-current process, $eN \to eX$, is parity conserving at low Q^2 and can be written in terms of two structure functions $F_1^{\rm NC}(x,Q^2)$ and $F_2^{\rm NC}(x,Q^2)$:

$$\frac{d^2\sigma}{dx\,dy} = \frac{4\pi\,\alpha^2(s - M^2)}{Q^4}$$

$$\times\left[(1-y)\,F_2^{\rm NC} + y^2\,xF_1^{\rm NC} - \frac{M^2}{(s-M^2)}\,xy\,F_2^{\rm NC}\right]\ . \qquad (24.2)$$

The charged-current processes, $e^-N \to \nu X$, $\nu N \to e^- X$, and $\overline{\nu}N \to e^+X$, are parity violating and can be written in terms of three structure functions $F_1^{\rm CC}(x,Q^2)$, $F_2^{\rm CC}(x,Q^2)$, and $F_3^{\rm CC}(x,Q^2)$:

$$\frac{d^2\sigma}{dx\,dy} = \frac{G_F^2\,(s-M^2)}{2\pi}\frac{M_W^4}{(Q^2+M_W^2)^2} \qquad (24.3)$$

$$\times\left\{\left[1 - y - \frac{M^2xy}{(s-M^2)}\right]F_2^{\rm CC} + \frac{y^2}{2}\,2x\,F_1^{\rm CC} \pm (y - \frac{y^2}{2})\,x\,F_3^{\rm CC}\right\},$$

where the last term is positive for the e^- and ν reactions and negative for $\overline{\nu}N \to e^+X$.

24.1.3. ***The QCD parton model***: In the QCD parton model, the structure functions defined above can be expressed in terms of parton distribution functions. The quantity $f_i(x,Q^2)dx$ is the probability that a parton of type i (quark, antiquark, or gluon), carries a momentum fraction between x and $x + dx$ of the nucleon's momentum in a frame where the nucleon's momentum is large. For the cross section corresponding to the *neutral-current process* $ep \to eX$, we have for $s \gg M^2$ (in the case where the incoming electron is either left- (L) or right- (R) handed):

$$\frac{d^2\sigma}{dx\,dy} = \frac{\pi\alpha^2}{sx^2\,y^2}\left[\sum_q (x\,f_q\,(x,\,Q^2) + x\,f_{\overline{q}}\,(x,\,Q^2)\right]$$

$$\times\left[A_q + (1-y)^2\,B_q\right]\ . \qquad (24.4)$$

Here the index q refers to a quark flavor (*i.e.*, u, d, s, c, b, or t), and

$$A_q = \left(-q_q + g_{Lq}\,g_{Le}\,\frac{Q^2}{Q^2+M_Z^2}\right)^2 + \left(-q_q + g_{Rq}\,g_{Re}\,\frac{Q^2}{Q^2+M_Z^2}\right)^2\ . \qquad (24.5)$$

$$B_q = \left(-q_q + g_{Rq}\,g_{Le}\,\frac{Q^2}{Q^2+M_Z^2}\right)^2 + \left(-q_q + g_{Lq}\,g_{Re}\,\frac{Q^2}{Q^2+M_Z^2}\right)^2\ . \qquad (24.6)$$

Here q_q is the charge of flavor q. For a left-handed electron, $g_{Re} = 0$ and $g_{Le} = (-1/2 + \sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, while for a right-handed one, $g_{Le} = 0$ and $g_{Re} = (\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$. For the quarks, $g_{Lq} = (T_3 - q_q\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, and $g_{Rq} = (-q_q\sin^2\theta_W)\ /\ (\sin\theta_W\cos\theta_W)$.

For neutral-current *neutrino* (*antineutrino*) *scattering*, the same formula applies with g_{Le} replaced by $g_{L\nu} = 1/(2\sin\theta_W\cos\theta_W)$ ($g_{L\overline{\nu}} = 0$) and g_{Re} replaced by $g_{R\nu} = 0$ [$g_{R\overline{\nu}} = -1/(2\sin\theta_W\cos\theta_W)$].

In the case of the *charged-current processes* $e_L^-p \to \nu X$ and $\overline{\nu}p \to e^+X$, Eq. (24.3) applies with

$$F_2 = 2xF_1 = 2x\Big[f_u(x,Q^2) + f_c(x,Q^2)$$

$$+\ f_t(x,Q^2) + f_{\overline{d}}\,(x,Q^2) + f_{\overline{s}}\,(x,Q^2) + f_{\overline{b}}\,(x,Q^2)\Big]\ , \qquad (24.7)$$

$$F_3 = 2\Big[f_u(x,Q^2) + f_c(x,Q^2)$$

$$+\ f_t(x,Q^2) - f_{\overline{d}}\,(x,Q^2) - f_{\overline{s}}\,(x,Q^2) - f_{\overline{b}}\,(x,Q^2)\Big]\ . \qquad (24.8)$$

For the process $\nu p \to e^- X$:

$$F_2 = 2xF_1 = 2x\Big[f_d(x,Q^2) + f_s(x,Q^2)$$

$$+\ f_b(x,Q^2) + f_{\overline{u}}\,(x,Q^2) + f_{\overline{c}}\,(x,Q^2) + f_{\overline{t}}\,(x,Q^2)\Big]\ , \qquad (24.9)$$

$$F_3 = 2\Big[f_d(x,Q^2) + f_s(x,Q^2)$$

$$+\ f_b(x,Q^2) - f_{\overline{u}}\,(x,Q^2) - f_{\overline{c}}\,(x,Q^2) - f_{\overline{t}}\,(x,Q^2)\Big]\ . \qquad (24.10)$$

24.2. e^+e^- annihilation

For pointlike spin-1/2 fermions in the c.m., the differential cross section for $e^+e^- \to f\bar{f}$ via single photon annihilation is

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4s}\,\beta\,\left[1+\cos^2\theta + (1-\beta^2)\sin^2\theta\right] Q_f^2\,, \tag{24.11}$$

where β is the velocity of the final state fermion in the center of mass and Q_f is the charge of the fermion in units of the proton charge. For $\beta \to 1$,

$$\sigma = \frac{4\pi\alpha^2}{3s}\,Q_f^2 = \frac{86.8\,Q_f^2\;nb}{s(\mathrm{GeV}^2)}\,. \tag{24.12}$$

At higher energies the Z^0 (mass M_Z and width Γ_Z) must be included, and the differential cross section for $e^+e^- \to f\bar{f}$ becomes

$$\begin{aligned}\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4s}\,\beta\,\Big[&Q_f^2[1+\cos^2\theta+(1-\beta^2)\,\sin^2\theta] \\ &- 2Q_f\,\chi_1\Big\{VV_f\,[1+\cos^2\theta+(1-\beta^2)\,\sin^2\theta] - 2a_f\,\beta\cos\theta\Big\} \\ &+ \chi_2\Big\{V_f^2\,(1+V^2)\,[1+\cos^2\theta+(1-\beta^2)\,\sin^2\theta] \\ &+ \beta^2\,a_f^2(1+V^2)\,[1+\cos^2\theta] - 8\beta\,VV_f\,a_f\cos\theta\Big\}\Big]\,,\end{aligned} \tag{24.13}$$

$$\chi_1 = \frac{1}{16\sin^2\theta_W\cos^2\theta_W}\;\frac{s(s-M_Z^2)}{(s-M_Z^2)^2+\Gamma_Z^2M_Z^2}\,, \tag{24.14}$$

$$\chi_2 = \frac{1}{256\sin^4\theta_W\cos^4\theta_W}\;\frac{s^2}{(s-M_Z^2)^2+\Gamma_Z^2M_Z^2}\,, \tag{24.15}$$

$$V = -1+4\sin^2\theta_W\,, \tag{24.16}$$

$$a_f = 2T_{3f}\,, \tag{24.17}$$

$$V_f = 2T_{3f} - 4Q_f\sin^2\theta_W\,, \tag{24.18}$$

where the subscript f refers to the particular fermion and

$$T_3 = +1/2 \quad \text{for } \nu_e,\ \nu_\mu,\ \nu_\tau,\ u,\ c,\ t, \tag{24.19a}$$

$$T_3 = -1/2 \quad \text{for } e^-,\ \mu^-,\ \tau^-,\ d,\ s,\ b. \tag{24.19b}$$

24.3. Two-photon process at e^+e^- colliders

When an e^+ and an e^- collide with energies E_1 and E_2, they emit dn_1 and dn_2 virtual photons with energies ω_1 and ω_2 and 4-momenta q_1 and q_2. In the equivalent photon approximation, the cross section for $e^+e^- \to e^+e^-X$ is related to the cross section for $\gamma\gamma \to X$ by (Ref. 1)

$$d\sigma_{e^+e^-\to e^+e^-X}(s) = dn_1\,dn_2\,d\sigma_{\gamma\gamma\to X}(W^2) \tag{24.20}$$

where $s = 4E_1E_2$, $W^2 = 4\omega_1\omega_2$ and

$$dn_i = \frac{\alpha}{\pi}\left[1-\frac{\omega_i}{E_i}+\frac{\omega_i^2}{2E_i^2}-\frac{m_e^2\omega_i^2}{(-q_i^2)E_i^2}\right]\frac{d\omega_i}{\omega_i}\,\frac{d(-q_i^2)}{(-q_i^2)}\,. \tag{24.21}$$

After integration (including that over q_i^2 in the region $m_e^2\omega_i^2/E_i(E_i-\omega_i) \le -q_i^2 \le (-q^2)_{\max}$), the cross section is

$$\begin{aligned}\sigma_{e^+e^-\to e^+e^-X}(s) = \frac{\alpha^2}{\pi^2}\int_{z_{th}}^1 \frac{dz}{z}\Big[&f(z)\left(\ln\frac{(-q^2)_{\max}}{m_e^2z}-1\right)^2 \\ &-\frac{1}{3}\left(\ln\frac{1}{z}\right)^3\Big]\sigma_{\gamma\gamma\to X}(zs)\,;\end{aligned}$$

$$f(z) = \left(1+\tfrac{1}{2}z\right)^2\ln\frac{1}{z} - \tfrac{1}{2}(1-z)(3+z)\,;$$

$$z = \frac{W^2}{s}\,. \tag{24.22}$$

The quantity $(-q^2)_{\max}$ depends on properties of the produced system X, in particular, $(-q^2)_{\max} \sim m_\rho^2$ for hadron production ($X = h$) and $(-q^2)_{\max} \sim W^2$ for lepton pair production ($X = \ell^+\ell^-$, $\ell = e,\ \mu,\ \tau$).

For production of a resonance of mass m_R and spin $J \neq 1$

$$\begin{aligned}\sigma_{e^+e^-\to e^+e^-R}(s) = (2J+1)&\frac{8\alpha^2\Gamma_{R\to\gamma\gamma}}{m_R^3} \\ &\times\left[f(m_R^2/s)\left(\ln\frac{sm_V^2}{m_e^2m_R^2}-1\right)^2-\frac{1}{3}\left(\ln\frac{s}{m_R^2}\right)^3\right]\end{aligned} \tag{24.23}$$

where m_V is the mass that enters into the form factor of the $\gamma\gamma \to R$ transition: $m_V \sim m_\rho$ for $R = \pi^0,\ \rho^0,\ \omega,\ \phi,\ \ldots$, $m_V \sim m_R$ for $R = c\bar{c}$ or $b\bar{b}$ resonances.

24.4. Inclusive hadronic reactions

One-particle inclusive cross sections $Ed^3\sigma/d^3p$ for the production of a particle of momentum p are conveniently expressed in terms of rapidity (see above) and the momentum p_T transverse to the beam direction (defined in the center-of-mass frame)

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\,dy\,p_T\,dp_T}\,. \tag{24.24}$$

In the case of processes where p_T is large or the mass of the produced particle is large (here large means greater than 10 GeV), the parton model can be used to calculate the rate. Symbolically

$$\sigma_{\text{hadronic}} = \sum_{ij}\int f_i(x_1,\,Q^2)\,f_j(x_2,\,Q^2)\,dx_1\,dx_2\,\hat{\sigma}_{\text{partonic}}\,, \tag{24.25}$$

where $f_i(x,\,Q^2)$ is the parton distribution introduced above and Q is a typical momentum transfer in the partonic process and $\hat{\sigma}$ is the partonic cross section. Two examples will help to clarify. The production of a W^+ in pp reactions at rapidity y in the center-of-mass frame is given by

$$\begin{aligned}\frac{d\sigma}{dy} = \frac{G_F\,\pi\sqrt{2}}{3}\,&\times\tau\Big[\cos^2\theta_c\Big(u(x_1\,,\,M_W^2)\,\bar{d}\,(x_2,M_W^2) \\ &\qquad + u(x_2\,,\,M_W^2)\,\bar{d}\,(x_1,M_W^2)\Big) \\ &+ \sin^2\theta_c\Big(u(x_1\,,\,M_W^2)\,\bar{s}\,(x_2\,,\,M_W^2) \\ &\qquad + s(x_2,M_W^2)\,\bar{u}\,(x_1,M_W^2)\Big)\Big]\,,\end{aligned} \tag{24.26}$$

where $x_1 = \sqrt{\tau}\,e^y$, $x_2 = \sqrt{\tau}\,e^{-y}$, and $\tau = M_W^2/s$. Similarly the production of a jet in pp (or $p\bar{p}$) collisions is given by

$$\begin{aligned}\frac{d^3\sigma}{d^2p_T\,dy} = \sum_{ij}\int &f_i(x_1\,,\,p_T^2)\,f_j(x_2,p_T^2) \\ &\times\left[\hat{s}\,\frac{d\hat{\sigma}}{d\hat{t}}\right]_{ij}dx_1\,dx_2\,\delta(\hat{s}+\hat{t}+\hat{u})\,,\end{aligned} \tag{24.27}$$

where the summation is over quarks, gluons, and antiquarks. Here

$$s = (p_1 + p_2)^2 \ , \tag{24.28}$$

$$t = (p_1 - p_{\rm jet})^2 \ , \tag{24.29}$$

$$u = (p_2 - p_{\rm jet})^2 \ , \tag{24.30}$$

p_1 and p_2 are the momenta of the incoming p and p (or $\overline{p}$) and $\hat{s}$, $\hat{t}$, and $\hat{u}$ are s, t, and u with $p_1 \to x_1 p_1$ and $p_2 \to x_2 p_2$. The partonic cross section $\hat{s}[(d\hat{\sigma})/(d\hat{t})]$ can be found in Ref. 2. Example: for the process $gg \to q\overline{q}$,

$$\hat{s}\,\frac{d\sigma}{dt} = 3\alpha_s^2\,\frac{(\hat{t}^2+\hat{u}^2)}{8\hat{s}}\left[\frac{4}{9\hat{t}\hat{u}} - \frac{1}{\hat{s}^2}\right] \ . \tag{24.31}$$

The prediction of Eq. (24.27) is compared to data from the UA1 and UA2 collaborations in Fig. 32.7 in the Plots of Cross Sections and Related Quantities section of this *Review*.

24.5. One-particle inclusive distributions

In order to describe one-particle inclusive production in e^+e^- annihilation or deep inelastic scattering, it is convenient to introduce a fragmentation function $D_i^h\ (z,Q^2)/z$ which is the probability that a parton of type i and momentum p will fragment into a hadron of type h and momentum zp. The Q^2 evolution is predicted by QCD and is similar to that of the parton distribution functions [see section on Quantum Chromodynamics (Sec. 25 of this *Review*)]. The $D_i^h(z,Q^2)$ are normalized so that

$$\sum_h \int D_i^h\ (z,Q^2)dz = 1 \ . \tag{24.32}$$

If the contributions of the Z boson and three-jet events are neglected, the cross section for producing a hadron h in e^+e^- annihilation is given by

$$\frac{1}{\sigma_{\rm had}}\,\frac{d\sigma}{dz} = \frac{\sum_i e_i^2\ D_i^h\ (z,Q^2)}{\sum_i e_i^2} \ , \tag{24.33}$$

where e_i is the charge of quark-type i, $\sigma_{\rm had}$ is the total hadronic cross section, and the momentum of the hadron is $zE_{\rm cm}/2$.

In the case of deep inelastic muon scattering, the cross section for producing a hadron of energy E_h is given by

$$\frac{1}{\sigma_{\rm tot}}\,\frac{d\sigma}{dz} = \frac{\sum_i e_i^2\ q_i(x,Q^2)\ D_i^h(z,Q^2)}{\sum_i e_i^2\ q_i(x,Q^2)} \ , \tag{24.34}$$

where $E_h = \nu z$. (For the kinematics of deep inelastic scattering, see Sec. 23.4.2 of the Kinematics section of this *Review*.) The fragmentation functions for light and heavy quarks have a different z dependence; the former peak near $z = 0$. They are illustrated in Fig. 32.12 in the section on Plots of Cross Sections and Related Quantities (Sec. 33 of this *Review*).

25. QUANTUM CHROMODYNAMICS

25.1. The QCD Lagrangian

Prepared January 1994 by I. Hinchliffe.

Quantum Chromodynamics (QCD), the gauge field theory which describes the strong interactions of colored quarks and gluons, is one of the components of the SU(3)×SU(2)×U(1) Standard Model. A quark of specific flavor (such as a charm quark) comes in 3 colors; gluons come in eight colors; hadrons are color-singlet combinations of quarks, anti-quarks, and gluons. The Lagrangian describing the interactions of quarks and gluons is (up to gauge-fixing terms)

$$L_{\rm QCD} = -\frac{1}{4}F^{(a)}_{\mu\nu}\,F^{(a)\mu\nu} + i\sum_q \overline{\psi}^i_q\,\gamma^\mu\,(D_\mu)_{ij}\,\psi^j_q - \sum_q m_q\,\overline{\psi}^i_q\,\psi_{qi}\,, \tag{25.1}$$

$$F^{(a)}_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + g_s\,f_{abc}\,A^b_\mu\,A^c_\nu\,, \tag{25.2}$$

$$(D_\mu)_{ij} = \delta_{ij}\,\partial_\mu - ig_s\sum_a \frac{\lambda^a_{i,j}}{2}A^a_\mu\,, \tag{25.3}$$

where g_s is the QCD coupling constant, and the f_{abc} are the structure constants of the SU(3) algebra (the λ matrices and values for f_{abc} can be found in Sec. 21 of this *Review*). The $\psi^i_q(x)$ are the 4-component Dirac spinors associated with each quark field of (3) color i and flavor q and the $A^a_\mu(x)$ are the (8) Yang-Mills (gluon) fields. A complete list of the Feynman rules which derive from this Lagrangian, together with some useful color-algebra identities, can be found in Ref. 1.

The principle of "asymptotic freedom" (see below)

determines that the renormalized QCD coupling is small only at high energies, and it is only in this domain that high-precision tests—similar to those in QED—can be performed using perturbation theory. Nonetheless, there has been in recent years much progress in understanding and quantifying the predictions of QCD in the nonperturbative domain, for example in soft hadronic processes and on the lattice [2]. This short review will concentrate on QCD at short distances (large momentum transfers), where perturbation theory is the standard tool. It will discuss the processes that are used to determine the coupling constant of QCD. Other recent reviews of the coupling constant measurements may be consulted for a different perspective [3].

25.2. The QCD coupling and renormalization scheme

The renormalization scale dependence of the effective QCD coupling $\alpha_s = g_s^2/4\pi$ is controlled by the β-function:

$$\mu\frac{\partial\alpha_s}{\partial\mu} = -\frac{\beta_0}{2\pi}\alpha_s^2 - \frac{\beta_1}{4\pi^2}\alpha_s^3 - \frac{\beta_2}{64\pi^3}\alpha_s^3 - \cdots\,, \tag{25.4a}$$

$$\beta_0 = 11 - \frac{2}{3}n_f\,, \tag{25.4b}$$

$$\beta_1 = 51 - \frac{19}{3}n_f\,, \tag{25.4c}$$

$$\beta_2 = 2857 - \frac{5033}{9}n_f - \frac{325}{27}n_f^2\,, \tag{25.4d}$$

here n_f is the number of quarks with mass less than the energy scale μ. In solving this differential equation for α_s, a constant of integration is introduced. This constant is the one fundamental constant of QCD that must be determined from experiment. The most sensible choice for this constant is the value of α_s at a fixed-reference scale μ_0, but it is more conventional to introduce the dimensional parameter Λ since this provides a parametrization of the μ dependence of α_s. The definition of Λ is arbitrary. One way to define it (adopted here) is to write a solution of Eq. (25.4) as an expansion in inverse powers of $\ln(\mu^2)$:

$$\alpha_s(\mu) = \frac{4\pi}{\beta_0\,\ln(\mu^2/\Lambda^2)} \times\left[1 - \frac{2\beta_1}{\beta_0^2}\,\frac{\ln\left[\ln(\mu^2/\Lambda^2)\right]}{\ln(\mu^2/\Lambda^2)} + \frac{4\beta_1^2}{\beta_0^4\ln^2(\mu^2/\Lambda^2)} \times\left(\left(\ln\left[\ln(\mu^2/\Lambda^2)\right] - \frac{1}{2}\right)^2 + \frac{8\beta_2\beta_0}{\beta_1^2} - \frac{5}{4}\right)\right] \tag{25.5a}$$

The last term in this expansion is

$$\mathcal{O}\left(\frac{\ln^2\left[\ln(\mu^2/\Lambda^2)\right]}{\ln^3(\mu^2/\Lambda^2)}\right) \tag{25.5b}$$

and is usually neglected in the definition of Λ. We choose to include it even though its effect on $\alpha_s(\mu)$ is smaller than the experimental errors. For a fixed value of $\alpha_s(M_Z)$, the inclusion of this term shifts the value of Λ by ~ 15 MeV.

This solution illustrates the *asymptotic freedom* property: $\alpha_s \to 0$ as $\mu \to \infty$. Alternative definitions of Λ are possible. We adopt this as the standard. Values given by experiments using other definitions are adjusted as needed to meet our definition.

In the above discussion we have ignored quark-mass effects, *i.e.*, we have assumed an idealized situation where quarks of mass greater than μ are neglected completely. In this picture, the β-function coefficients change by discrete amounts as flavor thresholds are crossed when integrating the differential equation for α_s. It follows that, for a relationship such as Eq. (25.5) to remain valid for all values of μ, Λ must also change as flavor thresholds are crossed. This leads to the concept of a different Λ for each range of μ corresponding to an effective number of massless quarks: $\Lambda \to \Lambda^{(n_f)}$. There is some arbitrariness in how this relationship is set up. As an idealised case consider QCD with $n_f - 1$ massless quarks and one quark of mass M. Now imagine an experiment at energy scale μ; for example, this could be $e^+e^- \to$ *hadrons* at center of mass energy μ. If $\mu \gg M$, the mass M is negligible and the process well described by QCD with n_f massless flavors and its parameter $\Lambda^{(n_f)}$ up to terms of order M^2/μ^2. Conversely if $\mu \ll M$, the heavy quark plays no role and the process well described by QCD with $n_f - 1$ massless flavors and its parameter $\Lambda^{(n_f-1)}$ up to terms of order μ^2/M^2. If $\mu \sim M$ the effects of the quark mass are process dependent and cannot be absorbed into the running coupling.

A mass scale μ' is chosen where the relationship between $\Lambda^{(n_f-1)}$ and $\Lambda^{(n_f)}$ will be fixed. μ' should be of order M and the relationship should not depend on it. A prescription has been given [4] which has this property. We use this procedure choosing $\mu' = M_Q$, where M_Q is the mass of the value of the running quark mass defined in the $\overline{\rm MS}$ scheme (see the note on quark masses for more details) *i.e.* where $M_{\overline{\rm MS}}(M_Q) = M_Q$. Then [4]

$$\begin{aligned}\beta_0^{n_f-1}\ln\left(\frac{\Lambda^{(n_f)}}{\Lambda^{(n_f-1)}}\right)^2 &= (\beta_0^{n_f} - \beta_0^{n_f-1})\,\ln\left(\frac{M_Q}{\Lambda^{(n_f)}}^2\right) \\ &+ 2\left(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}}\right)\,\ln\left[\ln\left(\frac{M_Q}{\Lambda^{(n_f)}}\right)^2\right] \\ &- \frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}}\,\ln\left(\frac{\beta_0^{n_f}}{\beta_0^{n_f-1}}\right) \\ &+ \frac{4\frac{\beta_1^{n_f}}{(\beta_0^{n_f})^2}\left(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}}\right)\,\ln\left[\ln\left(\frac{M_Q}{\Lambda^{n_f}}\right)^2\right]}{\ln\left(\frac{M_Q}{\Lambda^{(n_f)}}\right)^2} \\ &+ \frac{\frac{1}{\beta_0^{n_f}}\left[\left(\frac{2\beta_1^{n_f}}{\beta_0^{n_f}}\right)^2 - \left(\frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}}\right)^2 - \frac{2\beta_2^{n_f}}{\beta_0^{n_f}} + \frac{2\beta_2^{n_f-1}}{\beta_0^{n_f-1}} - \frac{14}{9}\right]}{\ln\left(\frac{M_Q}{\Lambda^{(n_f)}}\right)^2}\end{aligned} \tag{25.6}$$

This result is valid to order α_s^3 (or alternatively to terms of order $1/\ln^2[(M_Q/\Lambda^{(n_f)})^2]$).

In the previous edition of this note an alternative matching was used [5]. This procedure required the equality $\alpha_s(\mu)^{(n_f)} = \alpha_s(\mu)^{(n_f-1)}$ for $\mu = M_Q$. This matching is somewhat arbitrary; a different relation between $\Lambda^{(n_f)}$ and $\Lambda^{(n_f-1)}$ would result if $\mu = M_Q/2$ were used. In practice the differences between the new and old procedures are very small. $\Lambda^{(5)} = 200$ MeV corresponds to $\Lambda^{(4)} = 289$ MeV in the old scheme and $\Lambda^{(4)} = 280$ MeV in the one now adopted. Note that these differences between $\Lambda^{(5)}$ and $\Lambda^{(4)}$ are numerically very significant.

Data from deep-inelastic scattering are in a range of energy where the bottom quark is not readily excited and hence these experiments quote $\Lambda^{(4)}_{\overline{\rm MS}}$. Most data from PEP, PETRA, TRISTAN, and LEP quote a value of $\Lambda^{(5)}_{\overline{\rm MS}}$ since these data are in an energy range where the bottom quark is light compared to the available energy. We have converted it to $\Lambda^{(4)}_{\overline{\rm MS}}$ as required. A few measurements, including the lattice gauge theory values from the ψ system and from τ decay are at sufficiently low energy that $\Lambda^{(3)}_{\overline{\rm MS}}$ is appropriate.

We turn now to a discussion of renormalization-scheme dependence in QCD. Although necessarily rather technical, this discussion is vital to understanding how α_s (or Λ) values can be measured and compared. See the review by Duke and Roberts [6] for further details.

Consider a "typical" QCD cross section which, when calculated perturbatively, starts at $\mathcal{O}(\alpha_s)$:

$$\sigma = A_1\,\alpha_s + A_2\,\alpha_s^2 + \cdots\,. \tag{25.7}$$

The coefficients A_1, A_2 come from calculating the appropriate Feynman diagrams. In performing such calculations various divergences arise, and these must be regulated in a consistent way. This requires a particular renormalization scheme (RS). The most commonly used one is the modified minimal subtraction ($\overline{\rm MS}$) scheme [7]. This involves continuing momentum integrals from 4 to $4{-}2\epsilon$ dimensions and then subtracting off the resulting $1/\epsilon$ poles and also $(\ln 4\pi - \gamma_E)$, which is another artifact of continuing the dimension. (Here γ_E is the Euler-Mascheroni constant.) To preserve the dimensionless nature of the coupling, a mass scale μ must also be introduced: $g \to \mu^\epsilon g$. The finite coefficients A_i thus obtained depend implicitly on the renormalization convention used and explicitly on the scale μ.

The first two coefficients (β_0, β_1) in Eq. (25.4) are independent of the choice of RS's. In contrast, the coefficients of terms proportional to α_s^n for $n > 3$ *are* RS-dependent. The form given above for β_2 is in the $\overline{\rm MS}$ scheme. It has become conventional to use the $\overline{\rm MS}$ scheme for calculating QCD cross sections beyond leading order.

The fundamental theorem of RS dependence is straightforward. Physical quantities, in particular the cross section, calculated to all orders in perturbation theory, do not depend on the RS. It follows that a truncated series *does* exhibit RS dependence. In practice, QCD cross sections are known to leading or to next-to-leading order or, in a very few cases, to next-to-next-to-leading order, and it is only the latter two cases, which have reduced RS dependence, that are useful for precision tests. At second order the RS dependence is completely given by one condition which can be taken to be the value of the renormalization scale μ. One therefore has to address the question of what is the "best" choice for μ. There is no definite answer to this question—higher-order corrections do not "fix" the scale, rather they render the theoretical predictions less sensitive to its variation.

One could imagine that choosing a scale μ characteristic of the typical energy scale (E) in the process would be most appropriate. In general a poor choice of scale generates terms of order $\ln(E/\mu)$ in the A_i's. More byzantine choices are the scale for which the next-to-leading-order correction vanishes ("Fastest Apparent Convergence [8]"), the scale for which the next-to-leading-order prediction is stationary [9] (*i.e.* the value of μ where $d\sigma/d\mu = 0$), or that dictated by the effective charge scheme [10].

An important corollary is that if the higher-order corrections are naturally small, then the additional uncertainties introduced by the μ dependence are likely to be less than the experimental measurement errors. There are some processes, however, for which the choice of scheme (*i.e.* the value of μ) *can* influence the extracted value of $\Lambda_{\overline{\rm MS}}$. There is no resolution to this problem other than to try to calculate even more terms in the perturbation series.

In the cases where the higher-order corrections to a process are known and are large, some caution should be exercised when quoting the value of α_s. In what follows we will attempt to indicate the size of the theoretical uncertainties on the extracted value of α_s. There are two simple ways to determine this error. First, we can estimate it by comparing the value of $\alpha_s(\mu)$ obtained by fitting data using the QCD formula to highest known order in α_s, and then comparing it with the value obtained using the next-to-highest-order formula (μ is chosen as the typical energy scale in the process). The corresponding Λ's are then obtained by evolving $\alpha_s(\mu)$ to $\mu = m_Z$ using Eq. (25.4) to the same order in α_s as the fit, and then converting to $\Lambda^{(4)}$ using Eq. (25.6). Alternatively, we can vary the value of μ over a reasonable range, extracting a value of Λ for each choice of μ. This method is of its nature imprecise since "reasonable" involves a subjective judgement. In either case, if the perturbation series is well behaved, the resulting error on Λ will be small.

25.3. QCD in deep-inelastic scattering

The original and still one of the most powerful quantitative tests of perturbative QCD is the breaking of Bjorken scaling in deep-inelastic lepton-hadron scattering. In the leading-logarithm approximation the measured structure functions $F_i(x, Q^2)$ are related to the quark distribution functions $q_i(x, Q^2)$ according to the naive parton model by the formulae in Sec. 24 of this *Review*. (In that section, q_i is denoted by the notation f_q). In describing the way in which scaling is broken in QCD, it is convenient to define nonsinglet and singlet quark distributions:

$$F^{NS} = q_i - q_j \qquad F^S = \sum_i (q_i + \overline{q}_i)\,. \tag{25.8}$$

The nonsinglet structure functions have nonzero values of flavor quantum numbers such as isospin or baryon number. The variation with Q^2 of these is described by the so-called Altarelli-Parisi equations [11]:

$$Q^2\,\frac{\partial F^{NS}}{\partial Q^2} = \frac{\alpha_s(|Q|)}{2\pi} P^{qq} * F^{NS} \tag{25.9a}$$

$$Q^2\,\frac{\partial}{\partial Q^2}\begin{pmatrix} F^S \\ G \end{pmatrix} = \frac{\alpha_s(|Q|)}{2\pi}\begin{pmatrix} P^{qq} & 2n_f P^{qg} \\ P^{gq} & P^{gg} \end{pmatrix} * \begin{pmatrix} F^S \\ G \end{pmatrix} \tag{25.9b}$$

where $*$ denotes a convolution integral:

$$f * g = \int_x^1 \frac{dy}{y}\, f(y)\, g\left(\frac{x}{y}\right)\,. \tag{25.10}$$

The leading-order Altarelli-Parisi splitting functions are

$$P^{qq} = \frac{4}{3}\left[\frac{1+x^2}{1-x}\right]_+ + 2\delta(1-x)\,, \tag{25.11a}$$

$$P^{qg} = \frac{1}{2}\left[x^2 + (1-x)^2\right]\,, \tag{25.11b}$$

$$P^{gq} = \frac{4}{3}\left[\frac{1+(1-x)^2}{x}\right]\,, \tag{25.11c}$$

$$P^{gg} = 6\left[\frac{1-x}{x} + x(1-x) + \left(\frac{x}{1-x}\right)_+ + \frac{11}{12}\delta(1-x)\right] - \frac{n_f}{3}\delta(1-x)\,. \tag{25.11d}$$

Here the gluon distribution $G(x, Q^2)$ has been introduced and $1/(1-x)_+$ means

$$\int_0^1 dx \frac{f(x)}{(1-x)_+} = \int_0^1 dx\, \frac{f(x) - f(1)}{(1-x)}\,. \tag{25.12}$$

The precision of contemporary experimental data demands that higher-order corrections also be included [12]. The above results are for massless quarks. Algorithms exist for the inclusion of nonzero quark masses [13]. At low Q^2 values there are also important "higher-twist" (HT) or nonperturbutive contributions of the form:

$$F_i(x,Q^2) = F_i^{(LT)}(x,Q^2) + \frac{F_i^{(HT)}(x,Q^2)}{Q^2} + \cdots . \qquad (25.13)$$

Leading twist (LT) indicates a term whose behavior is predicted by perturbative QCD. These corrections are numerically important only for $Q^2 < \mathcal{O}(10\,\mathrm{GeV}^2)$ except for x very close to 1.

A detailed review of the current status of the experimental data can be found, for example, in [14], [15] and only a brief summary will be presented here. Since the last version of this *Review* [16] appeared, the discrepancies between different experiments have mostly been resolved. We shall only include determinations of Λ from the recently published results; the earlier editions of this *Review* should be consulted for the earlier data. In any event, the recent results will dominate the average since their errors are smaller.

From Eq. (25.9), it is clear that a nonsinglet structure function offers in principle the most precise test of the theory, since the Q^2 evolution is independent of the unmeasured gluon distribution. The CCFRR collaboration fit to the Gross-Llewellyn Smith sum rule [17] is known to order α_s^3 [18]

$$\int_0^1 dx(F_3^{\bar{\nu}p}(x,Q^2) + F_3^{\nu p}(x,Q^2)) =$$
$$3\left[(1 - \frac{\alpha_s}{\pi}(1 + 3.58\frac{\alpha_s}{\pi} + 19.0(\frac{\alpha_s}{\pi})^2) - \Delta HT\right] . \qquad (25.14)$$

Where the higher-twist contribution $\Delta HT = 0.032 \pm 0.016$ [18] Using the CCFRR data [19] this gives $\alpha_s(1.73\ \mathrm{GeV}) = 0.320 \pm 0.043(\mathrm{expt.}) \pm 0.029(\mathrm{theory})$. The error from higher-twist terms dominates the theoretical error, the higher-twist term being approximately 50% larger than the α_s^3 term. Recently a measurement of Λ has been made using F_3 in neutrino scattering [20]. The result is $\Lambda^{(4)}_{\overline{\mathrm{MS}}} = 179 \pm 36 \pm 41$ MeV. The errors are statistical and systematic but do not include (theoretical) errors arising from the choice of μ^2. Measurements involving singlet-dominated structure functions such as F_2 result in correlated measurements of $\Lambda^{(4)}_{\overline{\mathrm{MS}}}$ and the gluon distribution. By utilizing high-statistics data at large x (> 0.25) and large Q^2, where F_2 behaves like an nonsinglet and F_3 at smaller x a nonsinglet fit can be performed with better statistical precision and hence the error on the measured value of $\Lambda^{(4)}_{\overline{\mathrm{MS}}}$ is much reduced. CCFRR gives $\Lambda^{(4)}_{\overline{\mathrm{MS}}} = 210 \pm 28 \pm 41$ MeV [20] from $F_2(\nu N)$ and $F_3(\nu N)$. There is an additional uncertainty of ± 59 MeV from the choice of scale. The NMC collaboration [21] gives $\alpha_s(7\ \mathrm{GeV}^2) = 0.264 \pm 0.018(\mathrm{stat.}) \pm 0.070(\mathrm{syst.}) \pm 0.013(\mathrm{higher\text{-}twist})$. The systematic error is larger than the CCFRR result, partially because the data are at smaller values of x and the gluon distribution is more important. A reanalysis [22] of EMC data [23] gives $\Lambda^{(4)}_{\overline{\mathrm{MS}}} = 211 \pm 80 \pm 80$ MeV from $F_2(\nu N)$. Finally a combined analysis [24] of SLAC [25] and BCDMS [26] data gives $\Lambda^{(4)}_{\overline{\mathrm{MS}}} = 263 \pm 42 \pm 55$ MeV. Here the systematic error is an estimate of the uncertainty due to the choice of Q^2 used in the argument of α_s and in the scale at which the structure functions (factorization scale) used in the QCD calculation are evaluated.

The results from [20–22] and [24] can be combined to give $\alpha_s(M_Z) = 0.112 \pm 0.002 \pm 0.004$ or equivalently $\Lambda^{(4)}_{\overline{\mathrm{MS}}} = 234 \pm 26 \pm 50$ MeV. Here the former error is a combination of statistical and systematic errors and the second error is due to the scale uncertainty. This result is an average of the results weighted by their statistical and systematic errors. The scale error which is common to all is then reapplied to the average.

Typically, Λ is extracted from the data by parametrizing the parton densities in a simple analytic way at some Q_0^2, evolving to higher Q^2 using the next-to-leading-order evolution equations, and fitting globally to the measured structure functions to obtain $\Lambda^{(4)}_{\overline{\mathrm{MS}}}$. Thus an important by-product of such studies is the extraction of parton densities at a fixed-reference value of Q_0^2. These can then be evolved in Q^2 and used as input for phenomenological studies in hadron-hadron collisions (see below). To avoid having to evolve from the starting Q_0^2 value each time, a parton density is required; it is useful to have available a simple analytic approximation to the densities valid over a range of x and Q^2 values. A package is available in the from the CERN computer library that includes an exhaustive set of fits [27]. Some of these fits are obsolete. In using a parameterization to predict event rates, a next-to-leading order fit must be used if the process being calculated is known to next-to-leading order in QCD perturbation theory. In such a case there is an additional scheme dependence; this scheme dependence is reflected in the $\mathcal{O}(\alpha_s)$ corrections that appear in the relations between the structure functions and the quark distribution functions. There are two common schemes, a deep-inelastic scheme where there are no order α_s corrections in the formula for $F_2(x,Q^2)$ and the minimal subtraction scheme. It is important, when these next-to-leading order fits are used in other processes (see below), that the same scheme is used in the calculation of the partonic rates.

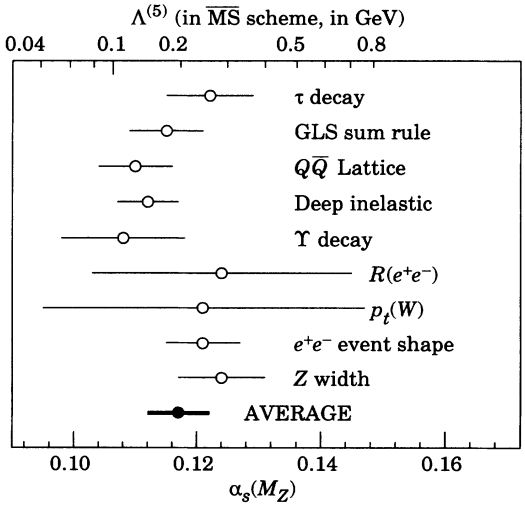

Figure 25.1: Summary of the values of $\alpha_s(M_Z)$ and $\Lambda^{(5)}$ from various processes ordered from top to bottom by increasing energy scale of the measurements. The values shown indicate the process and the measured value of α_s extrapolated up to $\mu = M_Z$. The error shown is the *total* error including theoretical uncertainties. The weighted average is obtained from the above values using the method discussed in the text.

25.4. QCD in decays of the tau lepton

The semi-leptonic branching ratio of the tau (R_τ) is an inclusive quantity. It is related to the contribution of hadrons to the imaginary part of the W self energy ($\Pi(s)$), just as R (see below, Sec. 25.7) is related to the imaginary part of the photon self energy. However it is more inclusive than R since it involves an integral

$$R_\tau \sim \int_0^{m_\tau^2} \frac{ds}{m_\tau^2}(1 - \frac{s}{m_\tau^2})^2 \mathrm{Im}(\Pi(s))$$

Since the scale involved is low, one must take into account nonperturbative (higher-twist) contributions which are suppressed by powers of the tau mass.

$$R_\tau = 3.058\left[1 + \frac{\alpha_s(m_\tau)}{\pi} + 5.2\left(\frac{\alpha_s(m_\tau)}{\pi}\right)^2 + 26.4\left(\frac{\alpha_s(m_\tau)}{\pi}\right)^3 + a\frac{m^2}{m_\tau^2} + b\frac{m\psi\overline{\psi}}{m_\tau^4} + c\frac{\psi\overline{\psi}\psi\overline{\psi}}{m_\tau^6} + \cdots\right]$$

Here a, b, and c are dimensionless constants and m is a light quark mass. The term of order $1/m_\tau^2$ is a kinematical effect due to the light quark masses and is consequently very small. The nonperturbative terms are estimated using sum rules [28]. In total they are estimated to be -0.007 ± 0.004 [29]. This estimate relies on there being no term of order Λ^2/m_τ^2 (note that $\frac{\alpha_s(m_\tau)}{\pi} \sim (\frac{0.5\ \text{GeV}}{m_\tau})^2$). The a, b and c can be determined from the data [30] by fitting to moments of the $\Pi(s)$. The values so extracted [31] are consistent with the theoretical estimates. If the nonperturbative terms are omitted from the fit, the extracted value of $\alpha_s(m_\tau)$ decreases by ~ 0.02.

For $\alpha_s(m_\tau) = 0.36$ the perturbative series for R_τ is $R_\tau \sim 3.058(1 + 0.114 + 0.073 + 0.043)$. The size (estimated error) of the nonperturbative term is 20% (7%) of the size of the order α_s^3 term. The perturbation series in not very well convergent; if the order α_s^3 term is omitted the extracted value of $\alpha_s(m_\tau)$ increases by 0.05. Using the experimental average [32] for R_τ of 3.6174 ± 0.034 gives $\alpha_s(m_\tau) = 0.360 \pm 0.031$ using the experimental error alone. We assign a theoretical error equal to 1/2 of the contribution from the order α^3 and nonperturbative contributions. This then gives $\alpha_s(m_\tau) = 0.360 \pm 0.041$ for the final result. Note that the experimental errors are dominant. The small theoretical errors have been criticised [33]. Here it is claimed that the presence of hadronic resonances limits the applicability of perturbative QCD and that the theoretical errors are underestimated by at least a factor of 2. If this argument is correct the agreement with values of α_s from other processes is accidental.

25.5. QCD in high-energy hadron collisions

There are many ways in which perturbative QCD can be tested in high-energy hadron colliders. The quantitative tests are only useful if the process in question has been calculated beyond leading order in QCD perturbation theory. The production of hadrons with large transverse momentum in hadron-hadron collisions provides a direct probe of the scattering of quarks and gluons: $qq \to qq$, $qg \to qg$, $gg \to gg$, *etc.* The present generation of $p\overline{p}$ colliders provide center-of-mass energies which are sufficiently high that these processes can be unambiguously identified in two-jet production at large transverse momentum. Recent higher-order QCD calculations of the jet rates [34] and shapes are in impressive agreement with data [35]. As an example, Fig. 32.7 in this *Review* shows the inclusive jet cross section at zero pseudorapidity as a function of the jet transverse momentum for $p\overline{p}$ collisions. Data are also available on the angular distribution of jets; these are also in agreement with QCD expectations [36,37].

QCD corrections to Drell-Yan type cross sections (*i.e.*, the production in hadron collisions by quark-antiquark annihilation of lepton pairs of invariant mass Q from virtual photons, or of real W or Z bosons) are known [38]. These $\mathcal{O}(\alpha_s)$ QCD corrections are sizable at small values of Q.

It is interesting to note that the corresponding correction to W and Z production, as measured in $p\overline{p}$ collisions at $\sqrt{s} = 0.63$ TeV and $\sqrt{s} = 1.8$ TeV has essentially the same theoretical form and is of order 30%.

The production of W and Z bosons and photons at large transverse momentum can also be used to determine α_s. The leading-order QCD subprocesses are $q\overline{q} \to \gamma g$ and $qg \to \gamma q$. If the parton distributions are taken from other processes and a value of $\Lambda^{(4)}_{\overline{\text{MS}}}$ assumed, then an absolute prediction is obtained. Conversely, the data can be used to extract information on quark and gluon distributions and on the value of $\Lambda^{(4)}_{\overline{\text{MS}}}$. The next-to-leading-order QCD corrections corrections are known [39,40] (for photons) and for W/Z production [41], and so a precision test is possible in principle. The UA2 collaboration [42] has extracted a value of $\alpha_s(M_W) = 0.123 \pm 0.018(\text{stat.}) \pm 0.017(\text{syst.})$ from the measured ratio $R_W = \frac{\sigma(W + 1jet)}{\sigma(W + 0jet)}$. The result depends on the algorithm used to define a jet, and the dominant systematic errors due to fragmentation and corrections for underlying events are connected to the algorithm (the former causes jet energy to be lost, the latter causes it to be increased). The scale at which $\alpha_s(M)$ is to be evaluated is not clear. A change from $M = M_W$ to $M = M_W/2$ causes a shift of 0.01 in the extracted α_s. The quoted error has been increased to take this into account.

25.6. QCD in heavy quarkonium decay

Under the assumption that the hadronic and leptonic decay widths of heavy $Q\overline{Q}$ resonances can be factorized into a nonperturbative part—dependent on the confining potential—and a calculable perturbative part, the ratios of partial decay widths allow measurements of α_s at the heavy quark mass scale. The most precise data come from the decay widths of the 1^{--} $J/\psi(1S)$ and Υ resonances. The total decay width of the Υ is predicted by perturbative QCD [43]

$$R_\Upsilon = \frac{\Gamma(\Upsilon \to \text{hadrons})}{\Gamma(\Upsilon \to \mu^+\mu^-)}$$
$$= \frac{10(\pi^2 - 9)\alpha_s^3(M)}{9\pi\alpha_{\text{em}}^2}\left[1 + \frac{\alpha_s}{\pi}\left(-19.4 + \frac{3\beta_0}{2}\left(1.162 + \ln\left(\frac{2M}{M_\Upsilon}\right)\right)\right)\right]$$

Data are available for the Υ, Υ', Υ'' and ψ. The result is very sensitive to α_s and the data are sufficiently precise ($R_\mu(\Upsilon) = 32.5 \pm 0.9$) [44] that the theoretical errors will dominate. There are theoretical corrections to this simple formula due to the relativistic nature of the $Q\overline{Q}$ system; $v^2/c^2 \sim 0.1$ for the Υ. They are more severe for the ψ. There are also nonperturbative corrections of the form Λ^2/m_Υ^2; again these are more severe for the ψ. A fit to Υ, Υ', and Υ'' [45] gives $\alpha_s(M_Z) = 0.108 \pm 0.001(\text{expt.})$. The results from each state separately and also from the ψ are consistent with each other. There is an uncertainty of order ± 0.005 from the choice of scale; the error from v^2/c^2 corrections is a little larger. $\alpha_s(M_Z) = 0.108 \pm 0.010$ is a fair representation of the total error including the possibility of nonperturbative corrections.

25.7. Perturbative QCD in e^+e^- collisions

The total cross section for $e^+e^- \to$ hadrons is obtained (at low values of $\sqrt{s}$) by multiplying the muon-pair cross section by the factor $R = 3\Sigma_q e_q^2$. The higher-order QCD corrections to this quantity have been calculated, and the results can be expressed in terms of the factor:

$$R = R^{(0)}\left[1 + \frac{\alpha_s}{\pi} + C_2\left(\frac{\alpha_s}{\pi}\right)^2 + C_3\left(\frac{\alpha_s}{\pi}\right)^3 + \cdots\right], \qquad (25.15)$$

where $C_2 = 1.411$ and $C_3 = -12.8$ [46].

$R^{(0)}$ can be obtained from the formula for $d\sigma/d\Omega$ for $e^+e^- \to f\overline{f}$ by integrating over Ω. The formula is given in Sec. 24.2 of this *Review*. This result is strictly only correct in the zero-quark-mass limit. The $\mathcal{O}(\alpha_s)$ corrections are also known for massive quarks [47].

A comparison of the theoretical prediction of Eq. (25.15) (corrected for the b-quark mass) with all the available data at values of $\sqrt{s}$ between 20 and 65 GeV gives [48] $\alpha_s(35\ \text{GeV}) = 0.146 \pm 0.030$. The principal advantage of determining α_s from R in e^+e^- annihilation is that there is no dependence on fragmentation models, jet algorithms, *etc.* The size of the order α_s^3 term is of order 40% of that of the order α_s^2 and 3% of the order α_s. If the order α_s^3 term is not included a fit to the data yields $\alpha_s(34\ \text{GeV}) = 0.142 \pm 0.03$, indicating that the theoretical uncertainty is smaller than the experimental error.

Measurements of the ratio of hadronic to leptonic width of the Z at LEP Γ_h/Γ_μ probe the same quantity as R. Using the average of $\Gamma_h/\Gamma_\mu = 20.781 \pm 0.049$ gives $\alpha_s(M_Z) = 0.124 \pm 0.007$ [49]. There are theoretical errors arising from the values of the top quark and Higgs masses which enter due to electroweak corrections to the Z width and from the choice of scale. The dominant error is the first of these (± 0.005).

An alternative method of determining α_s in e^+e^- annihilation is from measuring quantities that are sensitive to the relative rates of two-, three-, and four-jet events. In addition to simply counting jets, there are many possible choices of such "shape variables": thrust [50], energy-energy correlations [51], planar triple-energy correlations [52], average jet mass, *etc.* All of these are infrared safe, which means they can be reliably calculated in perturbation theory. The starting point

for all these quantities is the multijet cross section. For example, at order α_s, for the process $e^+e^- \to qqg$:

$$\frac{1}{\sigma}\frac{d^2\sigma}{dx_1 dx_2} = \frac{2\alpha_s}{3\pi}\frac{x_1^2+x_2^2}{(1-x_1)(1-x_2)}\,, \tag{25.16}$$

where

$$x_i = \frac{2E_i}{\sqrt{s}} \tag{25.17}$$

are the center-of-mass energy fractions of the final-state (massless) quarks. A distribution in a "three-jet" variable, such as those listed above, is obtained by integrating this differential cross section over an appropriate phase space region for a fixed value of the variable. The order α_s^2 corrections to this process have been computed as well as the 4-jet final states such as $e^+e^- \to qqgg$.

There are many methods used by the LEP groups [53–56] to determine α_s from the event topology. The jet-counting algorithm originally introduced by the JADE collaboration [57] has been used by the LEP groups. Here particles of momenta p_i and p_j are combined into a pseudo-particle of momentum $p_i + p_j$ if the invariant mass of the pair is less than $y_0\sqrt{s}$. The process is then iterated until no more pairs of particles or pseudo-particles remain. The remaining number is then defined to be the number of jets in the event and can be compared to the QCD prediction.

There are theoretical ambiguities in the way that this process is carried out; quarks and gluons are massless whereas the observed hadrons are not. So that the massive jets that result from this scheme cannot be compared directly to the massless jets of perturbative QCD. Different recombination schemes have been tried, for example combining 3-momenta and then rescaling the energy of the cluster so that it remains massless, and these result in the same data giving a slightly different value [58] of α_s. These differences can be used to determine a systematic error. In addition, since what is observed is hadrons rather than quarks and gluons, a model is needed to describe the evolution of a partonic final state into one involving hadrons so that detector corrections can be applied. The second-order matrix elements are combined with a parton-fragmentation model. This model can then be used to correct the data for a direct comparison with the parton calculation. The different hadronization models that are used [59–62] model the dynamics that are controlled by nonperturbative QCD effects which we cannot yet calculate. The fragmentation parameters of these Monte Carlos are tuned to get agreement with the observed data. The differences between these models contribute to the systematic errors. The systematic errors from recombination schemes and fragmentation effects dominate over the statistical and other errors of the LEP experiments.

The scale M at which $\alpha_s(M)$ is to be evaluated is not clear. The invariant mass of a typical jet (or $\sqrt{sy_0}$) is probably a more appropriate choice than the e^+e^- center of mass energy. If the value is allowed to float in the fit to the data, the data tend to prefer values of order $\sqrt{s}/10$ [63]; the exact value depends on the variable that is fitted. The dominant uncertainties arise from the choice of M and from the freedom in the fragmentation Monte Carlos. An average of many variables and all the LEP experiments [65] gives $\alpha_s(M_Z) = 0.119 \pm 0.006$. The dominant error is theoretical. The situation might improve if complete perturbative calculations to order α_s^3 became available.

The perturbative QCD formulae can break down in special kinematical configurations. For example, the thrust distribution contains terms of the type $\alpha_s \ln^2(1-T)$. The higher orders in the perturbation expansion contains terms of order $\alpha_s^n \ln^m(1-T)$. For $T \sim 1$ (the region populated by 2-jet events) the perturbation expansion is unreliable. The terms with $n \leq m$ can be summed to all orders in α_s [66]. The resummed results give better agreement with the data at large values of T [67]. Such resummed results are not available for all of the shape variables [69], but fits using those available yields a LEP average of $\alpha_s(M_Z) = 0.124 \pm 0.006$ [65]. Some caution should be exercised in using these resummed results because of the possibility of overcounting; the showering Monte Carlos that are used for the fragmentation corrections also generate some of these leading log corrections. The errors in the values of $\alpha_s(M_Z)$ from these shape variables are totally dominated by the theoretical uncertainties associated with the choice of scale and the effects of hadronization Monte Carlos. It is gratifying that the shift from the result using the unresummed formulae is less than the error. Since the data fitted to the resummed and not-resummed formulae are the same. We will use the average of $\alpha_s(M_Z) = 0.121 \pm 0.006$. Since the error is dominantly theoretical, it does not reduce in the average.

Similar studies on event shapes have been undertaken at TRISTAN and at PEP/PETRA. A combined result from various shape parameters by the TOPAZ collaboration gives $\alpha_s(58\ \text{GeV}) = 0.125 \pm 0.009$ using the fixed order QCD result and $\alpha_s(58\ \text{GeV}) = 0.132 \pm 0.008$ using the resummed result [70]. We average these and use $\alpha_s(58\ \text{GeV}) = 0.128 \pm 0.009$. The AMY group has fitted a next to leading order QCD Monte Carlo [68] to the single particle momentum distribution inside jets. The analysis is analogous to the fitting of moments in deep-inelastic scattering. They quote $\alpha_s(58\ \text{GeV}) = 0.134 \pm 0.006$ [71]. Jets are selected so that they are dominantly quark jets since the Monte Carlo does not well describe gluon jets. No systematic error is included for the contribution of gluon jets to the result. The errors could be understated therefore and we have chosen to use $\alpha_s(58\ \text{GeV}) = 0.134 \pm 0.008$ in order to be conservative.

The measurements of event shapes at PEP/PETRA are summarized in earlier editions of this note. The results are consistent with those from Z decay, but have larger errors. We use $\alpha_s(34\ \text{GeV}) = 0.14 \pm 0.02$ [72] Since the errors in the event shape measurements are dominantly systematic, the results from PEP/PETRA, TRISTAN and LEP are combined to give $\alpha_s(M_Z) = 0.121 \pm 0.006$. This result is then used in forming the final average value of α_s.

There are many other ways in which QCD can be tested in electron-positron collisions. Mention should be made in particular of the interesting and important results from "two-photon" processes. See the previous edition of this *Review* [16] for more information. There are no new results and the data do not contribute significantly to the average.

25.8. Lattice QCD

Lattice gauge theory calculations can be used to calculated the energy levels of a $Q\overline{Q}$ system and then extract α_s. The FNAL group [73] uses the splitting between the $1S$ and $1P$ in the charmonium system $[m_{h_c} - (3m_\psi + m_{\eta_c})/4 = 456.6 \pm 0.4\ \text{MeV}]$. to determine α_s. The result quoted is $\alpha_s(M_Z) = 0.108 \pm 0.006$. The splitting is almost independent of the charm-quark mass and is therefore dependent only on Λ. The calculation does not rely on perturbation theory or on nonrelativistic approximation. The main errors are systematic associated with the finite lattice spacing (a), the matching to the perturbatively defined α_s, and quenched approximation used in the calculation. The extrapolation to zero-lattice spacing produces a shift in Λ of order 5% and is therefore quite small. The quenched approximation is more serious. No light quarks are allowed to propagate and hence the extracted value of Λ corresponds to the case of zero flavors. $\alpha_s(M)$ is evolved down from the scale (~ 2.3 GeV) of the lattice used to the scale of momentum transfers appropriate to the charmonium system (~ 700 MeV). The resulting coupling is then evolved back up with the correct number of quark flavors. This produces a shift in $\alpha_s(5\ \text{GeV})$ of order 25%, with a claimed uncertainty of 7%. This error dominates and could be an underestimate as the perturbative running of $\alpha_s(M)$ has to be used at small M. In addition a recent calculation [74] using the strength of the force between two heavy quarks computed in the quenched approximation obtains a value of $\alpha_s(5\ \text{GeV})$ that is consistent with this result. Calculations based on the Υ spectrum using non-relativistic lattice theory give $\alpha_s(M_Z) = 0.112 \pm 0.004$ [75]. Here again the dominant error arises from the quenched approximation. We average the two results since they have a common systematic error and use $\alpha_s(M_Z) = 0.110 \pm 0.006$ in the final average.

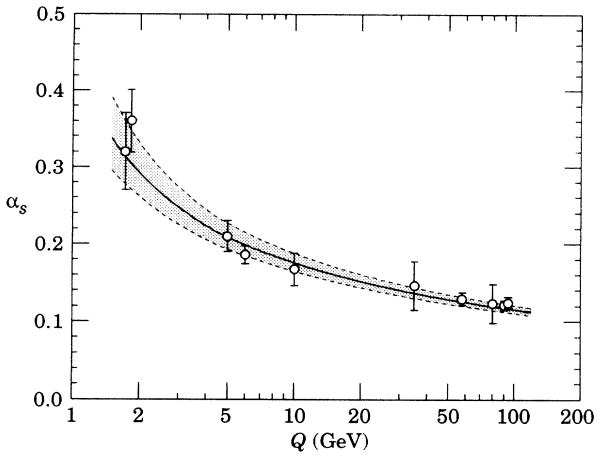

Figure 25.2: Summary of the values of $\alpha_s(\mu)$ at the values of μ where they are measured. The lines show the central values and the $\pm 1\sigma$ limits of our average. The figure clearly shows the decrease in $\alpha_s(\mu)$ with increasing μ.

25.9. Conclusions

The need for brevity has meant that many other important topics in QCD phenomenology have had to be omitted from this review. One should mention in particular the study of exclusive processes (form factors, elastic scattering, ...), the behavior of quarks and gluons in nuclei, the spin properties of the theory and the importance of polarized scattering data, the interface of soft and hard QCD as manifest, for example, by minijet production and hard diffractive processes, and QCD effects in hadron spectroscopy.

In this short review we have focused on those high-energy processes which currently offer the most quantitative tests of perturbative QCD. Emphasis has been given to the recent data from LEP and deep-inelastic scattering. Figure 25.1 shows the values of $\alpha_s(M_Z)$ deduced from the various experiments. Figure 25.2 shows the values and the values of Q where they are measured. This figure clearly shows the experimental evidence for the variation of $\alpha_s(Q)$ with Q.

An average of the values in Fig. 25.1 gives $\alpha_s(M_z) = 0.117$ with a total χ^2 of 5.9 for nine fitted points. The error on the average assuming that all of the errors in the contributing results are uncorrelated is ± 0.0023 and is surely an underestimate. Since, in most cases the dominant error is systematic (mainly theoretical), a more reasonable estimate is to use the smallest of the individual errors on the experimental results *i.e.* ± 0.005. Our value is then $\alpha_s(M_z) = 0.117 \pm 0.005$ which corresponds to $\Lambda^{(5)} = 195 + 65 - 50$ MeV.

The prospects for improvement in the error are controlled mainly by the potential improvements in the theoretical errors. Lattice calculations that do not resort to the quenched approximation offer one of the best opportunities. On the experimental side, the direct determination of the top quark mass and a smaller error on the hadronic width of the Z should result in a significantly reduced error on α_s.

26. STANDARD MODEL OF ELECTROWEAK INTERACTIONS

This section prepared May 1994 by P. Langacker and J. Erler.

The standard electroweak model is based on the gauge group [1] SU(2) × U(1), with gauge bosons W_μ^i, $i = 1,2,3$, and B_μ for the SU(2) and U(1) factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields $\psi_i = \begin{pmatrix} \nu_i \\ \ell_i^- \end{pmatrix}$ and $\begin{pmatrix} u_i \\ d_i' \end{pmatrix}$ of the i^{th} fermion family transform as doublets under SU(2), where $d_i' \equiv \sum_j V_{ij}\, d_j$, and V is the Cabibbo-Kobayashi-Maskawa mixing matrix.* The right-handed fields are SU(2) singlets. In the minimal model there are three fermion families and a single complex Higgs doublet $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$.

After spontaneous symmetry breaking the Lagrangian is

$$\begin{aligned}\mathscr{L}_F = &\sum_i \overline{\psi}_i \left(i\, \partial\!\!\!/ - m_i - \frac{g m_i H}{2M_W} \right) \psi_i \\ &- \frac{g}{2\sqrt{2}} \sum_i \overline{\psi}_i\, \gamma^\mu\, (1-\gamma^5)(T^+\, W_\mu^+ + T^-\, W_\mu^-)\, \psi_i \\ &- e \sum_i q_i\, \overline{\psi}_i\, \gamma^\mu\, \psi_i\, A_\mu \\ &- \frac{g}{2\cos\theta_W} \sum_i \overline{\psi}_i\, \gamma^\mu (g_V^i - g_A^i \gamma^5)\, \psi_i\, Z_\mu\ . \end{aligned} \tag{26.1}$$

$\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e = g \sin\theta_W$ is the positron electric charge; and $A \equiv B\cos\theta_W + W^3 \sin\theta_W$ is the (massless) photon field. $W^\pm \equiv (W^1 \mp i W^2)/\sqrt{2}$ and $Z \equiv -B\sin\theta_W + W^3 \cos\theta_W$ are the massive charged and neutral weak boson fields, respectively. T^+ and T^- are the weak isospin raising and lowering operators. The vector and axial couplings are

$$g_V^i \equiv t_{3L}(i) - 2 q_i \sin^2\theta_W \tag{26.2}$$

$$g_A^i \equiv t_{3L}(i)\ , \tag{26.3}$$

where $t_{3L}(i)$ is the weak isospin of fermion i ($+1/2$ for u_i and ν_i; $-1/2$ for d_i and e_i) and q_i is the charge of ψ_i in units of e.

The second term in $\mathscr{L}_F$ represents the charged-current weak interaction [2]. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W} \left[W_\mu^-\, \overline{e}\, \gamma^\mu (1-\gamma^5) \nu + W_\mu^+\, \overline{\nu}\, \gamma^\mu\, (1-\gamma^5) e \right]\ . \tag{26.4}$$

For momenta small compared to M_W, this term gives rise to the effective four-fermion interaction with the Fermi constant given (at tree level, *i.e.*, lowest order in perturbation theory) by $G_F/\sqrt{2} = g^2/8M_W^2$. CP violation is incorporated in the Standard Model by a single observable phase in V_{ij}. The third term in $\mathscr{L}_F$ describes electromagnetic interactions (QED), and the last is the weak neutral-current interaction.

In Eq. (26.1), m_i is the mass of the i^{th} fermion ψ_i. For the quarks these are the current masses. For the light quarks, a typical estimate [3] gives $m_u \approx 5.6 \pm 1.1$ MeV, $m_d \approx 9.9 \pm 1.1$ MeV, $m_s \approx 199 \pm 33$ MeV, and $m_c \approx 1.35 \pm 0.05$ GeV (these are running masses evaluated at 1 GeV). For the heavier quarks $m_b \approx 4.7$ GeV (the "pole" mass), and $m_t > 131$ GeV [4]. (The CDF Collaboration has reported [5] evidence for top events with $m_t = 174 \pm 16$ GeV.) See "The Note on Quark Masses" in the Full Listings for more information.

H is the physical neutral Higgs scalar which is the only remaining part of ϕ after spontaneous symmetry breaking. The Yukawa coupling of H to ψ_i, which is flavor diagonal in the minimal model, is $g m_i/2M_W$. The H mass is not predicted by the model. Experimental limits are given in the Higgs section. In nonminimal models there are additional charged and neutral scalar Higgs particles [6].

26.1. Renormalization and radiative corrections

The Standard Model has three parameters (not counting M_H and the fermion masses and mixings). A particularly useful set is:

(*a*) The fine structure constant $\alpha = 1/137.036$, determined from the quantum Hall effect. In most electroweak-renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with $\alpha^{-1} \sim 137$ appropriate at low energy. At energies of order M_Z, $\alpha^{-1} \sim 128$. For example, in the modified minimal subtraction ($\overline{\rm MS}$) scheme, one has $\widehat{\alpha}(M_Z)^{-1} = 127.9 \pm 0.1$ [7], with the uncertainty due to the low-energy hadronic contribution to vacuum polarization.

(*b*) The Fermi constant, $G_F = 1.16639(2) \times 10^{-5}$ GeV^{-2}, determined from the muon lifetime formula [8]:

$$\tau_\mu^{-1} = \frac{G_F^2 m_\mu^5}{192\pi^3} F\left(\frac{m_e^2}{m_\mu^2}\right) \left(1 + \frac{3}{5}\frac{m_\mu^2}{M_W^2}\right) \times \left[1 + \frac{\alpha(m_\mu)}{2\pi}\left(\frac{25}{4} - \pi^2\right)\right]\ , \tag{26.5a}$$

where

$$F(x) = 1 - 8x + 8x^3 - x^4 - 12x^2 \ln x \tag{26.5b}$$

and

$$\alpha(m_\mu)^{-1} = \alpha^{-1} - \frac{2}{3\pi}\ln\left(\frac{m_\mu}{m_e}\right) + \frac{1}{6\pi} \approx 136\ . \tag{26.5c}$$

The uncertainty in G_F from the input quantities is 1.1×10^{-10} GeV^{-2}. The quoted uncertainty of 2×10^{-10} is dominated by second order radiative corrections, estimated from the magnitude of the known $\alpha^2 \ln(m_\mu/m_e)$ term to be $\sim 1.8 \times 10^{-10}$ (alternately, one can view Eq. (26.5) as the exact definition of G_F; then the theoretical uncertainty appears instead in the formulae for quantities derived from G_F).

(*c*) $\sin^2\theta_W$, determined from the Z mass and other Z-pole observables, the W mass, and neutral-current processes [9]. The value of $\sin^2\theta_W$ depends on the renormalization prescription. There are a number of popular schemes [10–15] leading to $\sin^2\theta_W$ values which differ by small factors which depend on m_t and M_H. The notation for these schemes is shown in Table 26.1. Discussion of the schemes follows the table.

Table 26.1: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin\theta_W$ leads to values that differ by small factors depending on m_t and M_H.

Scheme	Notation
On-shell	$s_W = \sin\theta_W$
NOV	$s_{M_Z} = \sin\theta_W$
$\overline{\rm MS}$	$\widehat{s}_Z = \sin\theta_W$
$\overline{\rm MS}$ ND	$\widehat{s}_{ND} = \sin\theta_W$
Effective angle	$\overline{s}_f = \sin\theta_W$

(*i*) The on-shell scheme promotes the tree-level formula $\sin^2\theta_W = 1 - M_W^2/M_Z^2$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, *i.e.*, $\sin^2\theta_W \to s_W^2 \equiv 1 - M_W^2/M_Z^2$. This scheme is simple conceptually. However, M_W is known much less precisely than M_Z and in practice one extracts s_W^2 from M_Z alone using

$$M_W = \frac{A_0}{s_W (1-\Delta r)^{1/2}} \tag{26.6a}$$

$$M_Z = \frac{M_W}{c_W}\ , \tag{26.6b}$$

where $s_W \equiv \sin\theta_W$, $c_W \equiv \cos\theta_W$, $A_0 = (\pi\alpha/\sqrt{2}G_F)^{1/2} = 37.2802$ GeV, and Δr includes the radiative corrections relating α, $\alpha(M_Z)$, G_F, M_W, and M_Z. One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 \approx 1 - \alpha/\alpha(M_Z) \approx 0.07$ is due to the running of α and $\rho_t = 3G_F\, m_t^2/8\sqrt{2}\pi^2 \approx 0.0031\,(m_t/100\text{ GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on the Higgs mass M_H. For example, $\Delta r = 0.0475 \pm 0.0009$ for $(m_t, M_H) = (150, 300)$, while $\Delta r = 0.0327 \pm 0.0009$ for (190,300), where the 0.0009 uncertainty is from $\alpha(M_Z)$. Thus the value of s^2_W extracted from M_Z includes a large uncertainty (~ 0.002) from the currently allowed range of m_t.

(*ii*) A more precisely determined quantity $s^2_{M_Z}$ can be obtained from M_Z by removing the (m_t, M_H) dependent term from Δr [11], *i.e.*,

$$s^2_{M_Z} c^2_{M_Z} \equiv \frac{\pi\overline{\alpha}}{\sqrt{2}\,G_F\,M_Z^2}\ , \tag{26.7}$$

where $\overline{\alpha}^{-1} = \alpha(M_Z)^{-1} = 128.87 \pm 0.12$. [This is defined using the conventional QED renormalization, and differs by finite constants from $\widehat{\alpha}(M_Z)^{-1}$.] This yields $s^2_{M_Z} = 0.2312 \pm 0.0003$, with most of the uncertainty from $\overline{\alpha}$ rather than M_Z. Scheme (*ii*) is equivalent to using M_Z rather than $\sin^2\theta_W$ as the third fundamental parameter. However, it recognizes that $s^2_{M_Z}$ is still a useful derived quantity. The small uncertainty in $s^2_{M_Z}$ compared to other schemes is because the m_t dependence has been removed by definition. However, the m_t uncertainty reemerges when other quantities (*e.g.*, M_W or other Z-pole observables) are predicted in terms of M_Z. Both s^2_W and $s^2_{M_Z}$ depend not only on the gauge couplings but also on the spontaneous-symmetry breaking, and both definitions are awkward in the presence of any extension of the Standard Model which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$.

(*iii*) In particular, the modified minimal subtraction ($\overline{\rm MS}$) scheme introduces the quantity $\sin^2\widehat{\theta}_W(\mu) \equiv \widehat{g}'^2(\mu)/\left[\widehat{g}^2(\mu) + \widehat{g}'^2(\mu)\right]$, where the couplings $\widehat{g}$ and $\widehat{g}'$ are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for electroweak processes. The value of $\widehat{s}^2_Z = \sin^2\widehat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s^2_W to m_t (by a factor of $\tan^2\theta_W$), and is less sensitive to most types of new physics than s^2_W or $s^2_{M_Z}$. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2\widehat{\theta}_W(M_Z)$, differing according to whether or how finite $\alpha\ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha\ln(m_t/M_Z)$ terms from all electroweak quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha\ln(m_t/M_Z)$ terms from the $\gamma - Z$ mixing [7,12], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in terms of $\widehat{s}^2_Z$. The various definitions are related by

$$\widehat{s}^2_Z = c\,(m_t, M_H) s^2_W = \overline{c}\,(m_t, M_H)\, s^2_{M_Z}\ , \tag{26.8}$$

where $c = 1.025\,(1.041)$ for $m_t = 150\,(190)$ GeV and $M_H = 300$ GeV. Similarly $\overline{c}\,(150, 300) = 1.006$ and $\overline{c}\,(190, 300) = 1.0003$. The quadratic m_t dependence is given by $c \sim 1 + \rho_t/\tan^2\theta_W$. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\widehat{s}_Z(1 - \Delta\widehat{r}_W)^{1/2}} \tag{26.9a}$$

$$M_Z = \frac{M_W}{\widehat{\rho}^{1/2}\widehat{c}_Z}\ . \tag{26.9b}$$

One predicts $\Delta\widehat{r}_W = 0.0703\,(0.0708) \pm 0.0009$ for $m_t = 150\,(190)$ GeV and $M_H = 300$ GeV. $\Delta\widehat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F, so that $\Delta\widehat{r}_W$ is dominated by $\Delta r_0 = 1 - \alpha/\alpha(M_Z)$. Similarly, $\widehat{\rho} \sim 1 + \rho_t$. Including bosonic loops, $\widehat{\rho} = 1.0072\,(1.0118)$ for $m_t = 150\,(190)$ GeV.

(*iv*) A variant $\overline{\rm MS}$ quantity $\widehat{s}^2_{\rm ND}$ (used in the previous edition of this *Review*) does not decouple the $\alpha\ln(m_t/M_Z)$ terms [13]. It is related to $\widehat{s}^2_Z$ by

$$\widehat{s}^2_Z = \widehat{s}^2_{\rm ND}/\left(1 + \frac{\widehat{\alpha}}{\pi}d\right) \tag{26.10a}$$

$$d = \frac{1}{3}\left(\frac{1}{\widehat{s}^2} - \frac{8}{3}\right)\left[(1 + \frac{\widehat{\alpha}_s}{\pi})\ln\frac{m_t}{M_Z} - \frac{15\widehat{\alpha}_s}{\pi}\right]\ , \tag{26.10b}$$

where $\widehat{\alpha}_s$ is the QCD coupling at M_Z. Thus, $\widehat{s}^2_Z - \widehat{s}^2_{\rm ND} \sim -0.0001(-0.0002)$ for $m_t = 150\,(190)$ GeV and $M_H = 300$ GeV.

(*v*) Yet another definition, the effective angle [14,15] $\overline{s}^2_f$ for Z coupling to fermion f, is described below.

Experiments are now at such a level of precision that complete $\mathcal{O}(\alpha)$ radiative corrections must be applied. These corrections are conveniently divided into two classes:

1. QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs yield finite and gauge-invariant contributions to observable processes. However, they are dependent on energies, experimental cuts, *etc.*, and must be calculated individually for each experiment.
2. Electroweak corrections, including $\gamma\gamma$, γZ, ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs, *etc.*, involving virtual W's and Z's. Many of these corrections are absorbed into the renormalized Fermi constant defined in Eq. (26.5). Others modify the tree-level expressions for Z-pole observables and neutral-current amplitudes in several ways [9]. One-loop corrections are included for all processes. In addition, certain two-loop corrections are also important. In particular, two-loop corrections involving the top-quark [16] modify ρ_t in $\widehat{\rho}$, Δr, and elsewhere by

$$\rho_t \to \rho_t[1 + R(M_H/m_t)\rho_t/3]\ , \tag{26.11}$$

where R is strongly dependent om M_H/m_t, with $R(0) = 19 - 2\pi^2$. Similarly, mixed $(\alpha\alpha_s\, m_t^2)$ QCD-electroweak loops [17] multiply ρ_t by $1 - \alpha_s(m_t)(\pi^2 + 3)/9\pi \sim 0.9$, increasing the predicted value of m_t by $\sim 5\%$. Analogous mixed terms modify the $Z \to b\overline{b}$ vertex [18]. Recently, there has been discussion of threshold or higher-order corrections to this term, which have been estimated by both dispersion relation and perturbative methods [19,20]. One estimate [20] suggests that $\alpha_s(m_t)$ should be replaced by $\alpha_s(0.15\, m_t)$, raising the predicted m_t by ~ 3 GeV. However, these threshold effects are still uncertain and are therefore not included here.

26.2. Cross section and asymmetry formulas

It is convenient to write the four-fermion interactions relevant to ν-hadron, νe, and parity-violating e-hadron neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has

$$-\mathcal{L}^{\nu\text{Hadron}} = \frac{G_F}{\sqrt{2}}\,\overline{\nu}\,\gamma^\mu\,(1 - \gamma^5)\nu$$

$$\times\sum_i\left[\epsilon_L(i)\,\overline{q}_i\,\gamma_\mu(1 - \gamma^5)q_i + \epsilon_R(i)\,\overline{q}_i\,\gamma_\mu(1 + \gamma^5)q_i\right]\ , \tag{26.12}$$

$$-\mathcal{L}^{\nu e} = \frac{G_F}{\sqrt{2}}\,\overline{\nu}_\mu\,\gamma^\mu(1 - \gamma^5)\nu_\mu\,\overline{e}\,\gamma_\mu(g_V^{\nu e} - g_A^{\nu e}\gamma^5)e \tag{26.13}$$

(for $\nu_e e$ or $\overline{\nu}_e e$, the charged-current contribution must be included), and

$$-\mathscr{L}^{e\text{Hadron}} = -\frac{G_F}{\sqrt{2}} \times \sum_i \left[C_{1i}\, \overline{e}\, \gamma_\mu\, \gamma^5\, e\, \overline{q}_i\, \gamma^\mu\, q_i + C_{2i}\, \overline{e}\, \gamma_\mu\, e\, \overline{q}_i\, \gamma^\mu\, \gamma^5\, q_i\right] \quad (26.14)$$

(One must add the parity-conserving QED contribution.)

The Standard Model expressions for $\epsilon_{L,R}(i)$, $g_{V,A}^{\nu e}$, and C_{ij} are given in Table 26.2. Note that $g_{V,A}^{\nu e}$ and the other quantities are coefficients of effective four-fermi operators, which differ from the quantities defined in Eq. (26.2) and Eq. (26.3) in the radiative corrections and in the presence of possible physics beyond the Standard Model.

A precise determination of the on-shell s_W^2, which depends only very weakly on m_t and M_H, is obtained from deep inelastic neutrino scattering from (approximately) isoscalar targets. The ratio $R_\nu \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ of neutral- to charged-current cross sections has been measured to 1% accuracy by the CDHS [21] and CHARM [22] collaborations [23,24] at CERN, and the CCFR collaboration at Fermilab [25] has recently reported an even more precise result, so it is important to obtain theoretical expressions for R_ν and $R_{\overline{\nu}} \equiv \sigma_{\overline{\nu}N}^{NC}/\sigma_{\overline{\nu}N}^{CC}$ (as functions of $\sin^2\theta_W$) to comparable accuracy. Fortunately, most of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio.

Table 26.2: Standard Model expressions for the neutral-current parameters for ν-hadron, νe, and e-hadron processes. If radiative corrections are ignored, $\rho = \kappa = 1$, $\lambda = 0$. At $\mathcal{O}(\alpha)$ in the on-shell scheme, $\rho_{\nu N}^{NC} = 1.0083$, $\kappa_{\nu N} = 1.0330$, $\lambda_{u_L} = -0.0032$, $\lambda_{d_L} = -0.0026$, and $\lambda_{u_R} = 1/2\,\lambda_{d_R} = 3.6\times10^{-5}$ for $m_t = 169$ GeV, $M_H = 300$ GeV, $M_Z = 91.187$ GeV, and $\langle Q^2\rangle = 20$ GeV^2. For νe scattering, $\kappa_{\nu e} = 1.0332$ and $\rho_{\nu e} = 1.0131$ (at $\langle Q^2\rangle = 0$.). For atomic parity violation, $\rho'_{eq} = 0.9874$ and $\kappa'_{eq} = 1.033$. For the SLAC polarized electron experiment, $\rho'_{eq} = 0.978$, $\kappa'_{eq} = 1.031$, $\rho_{eq} = 1.001$, and $\kappa_{eq} = 1.06$ after incorporating additional QED corrections, while $\lambda_{2u} = -0.013$, $\lambda_{2d} = 0.003$. The dominant m_t dependence is given by $\rho \sim 1 + \rho_t$, while $\kappa \sim 1 + \rho_t/\tan^2\theta_W$ (on-shell) or $\kappa \sim 1(\overline{\text{MS}})$.

Quantity	Standard Model Expression
$\epsilon_L(u)$	$\rho_{\nu N}^{NC}\left(\frac{1}{2} - \frac{2}{3}\kappa_{\nu N}\,\sin^2\theta_W + \lambda_{uL}\right)$
$\epsilon_L(d)$	$\rho_{\nu N}^{NC}\left(-\frac{1}{2} + \frac{1}{3}\kappa_{\nu N}\,\sin^2\theta_W + \lambda_{dL}\right)$
$\epsilon_R(u)$	$\rho_{\nu N}^{NC}\left(-\frac{2}{3}\kappa_{\nu N}\,\sin^2\theta_W + \lambda_{uR}\right)$
$\epsilon_R(d)$	$\rho_{\nu N}^{NC}\left(\frac{1}{3}\kappa_{\nu N}\,\sin^2\theta_W + \lambda_{dR}\right)$
$g_V^{\nu e}$	$\rho_{\nu e}\left(-\frac{1}{2} + 2\kappa_{\nu e}\,\sin^2\theta_W\right)$
$g_A^{\nu e}$	$\rho_{\nu e}\left(-\frac{1}{2}\right)$
C_{1u}	$\rho'_{eq}\left(-\frac{1}{2} + \frac{4}{3}\kappa'_{eq}\,\sin^2\theta_W\right)$
C_{1d}	$\rho'_{eq}\left(\frac{1}{2} - \frac{2}{3}\kappa'_{eq}\,\sin^2\theta_W\right)$
C_{2u}	$\rho_{eq}\left(-\frac{1}{2} + 2\kappa_{eq}\,\sin^2\theta_W\right) + \lambda_{2u}$
C_{2d}	$\rho_{eq}\left(\frac{1}{2} - 2\kappa_{eq}\,\sin^2\theta_W\right) + \lambda_{2d}$

A simple zeroth-order approximation is

$$R_\nu = g_L^2 + g_R^2 r \quad (26.15a)$$

$$R_{\overline{\nu}} = g_L^2 + \frac{g_R^2}{r}\,, \quad (26.15b)$$

where

$$g_L^2 \equiv \epsilon_L\,(u)^2 + \epsilon_L\,(d)^2 \approx \frac{1}{2} - \sin^2\theta_W + \frac{5}{9}\sin^4\theta_W \quad (26.16a)$$

$$g_R^2 \equiv \epsilon_R\,(u)^2 + \epsilon_R\,(d)^2 \approx \frac{5}{9}\sin^4\theta_W\,, \quad (26.16b)$$

and $r \equiv \sigma_{\overline{\nu}N}^{CC}/\sigma_{\nu N}^{CC}$ is the ratio of $\overline{\nu}$ and ν charged-current cross sections, which can be measured directly. [In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3} + \epsilon)/(1 + \frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by antiquarks to that carried by quarks.] In practice, Eq. (26.15) must be corrected for quark mixing, the s and c seas, c-quark threshold effects, nonisoscalar target effects, W-Z propagator differences, and radiative corrections (which lower the extracted value of $\sin^2\theta_W$ by ~ 0.009). Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. The largest theoretical uncertainty is associated with the c threshold, which mainly affects σ^{CC}. Using the slow rescaling prescription [9] the central value of $\sin^2\theta_W$ varies as 0.013 $[m_c(\text{GeV})$–$1.3]$, where m_c is the effective mass. For $m_c = 1.31 \pm 0.24$ GeV (determined from ν-induced dimuon production [25]) this contributes ±0.003 to the total theoretical uncertainty $\Delta\sin^2\theta_W \sim \pm0.004$. This would require a high-energy neutrino beam for improvement. (The experimental uncertainty is ±0.003). The CCFR group quotes $s_W^2 = 0.2218 \pm 0.0059$ for $(m_t, M_H) = (150, 100)$, but this result is insensitive to (m_t, M_H). Combining all of the precise deep-inelastic measurements, one obtains $s_W^2 = 0.2260 \pm 0.0048$ for (m_t, M_H) in the allowed range.

The laboratory cross section for $\nu_\mu e \to \nu_\mu e$ or $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ elastic scattering is

$$\frac{d\sigma_{\nu_\mu,\overline{\nu}_\mu}}{dy} = \frac{G_F^2 m_e E_\nu}{2\pi} \times \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2(1-y)^2 - (g_V^{\nu e 2} - g_A^{\nu e 2})\frac{y\, m_e}{E_\nu}\right], \quad (26.17)$$

where the upper (lower) sign refers to $\nu_\mu(\overline{\nu}_\mu)$, and $y \equiv E_e/E_\nu$ [which runs from 0 to $(1 + m_e/2E_\nu)^{-1}$] is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_\nu \gg m_e$ this yields a total cross section

$$\sigma = \frac{G_F^2\, m_e\, E_\nu}{2\pi}\left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3}(g_V^{\nu e} \mp g_A^{\nu e})^2\right]. \quad (26.18)$$

The most accurate leptonic measurements [26–28] of $\sin^2\theta_W$ are from the ratio $R \equiv \sigma_{\nu_\mu e}/\sigma_{\overline{\nu}_\mu e}$ in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2\theta_W$. The most precise (CHARM II) experiment [28] determined not only $\sin^2\theta_W$ but $g_{V,A}^{\nu e}$ as well. The cross sections for $\nu_e e$ and $\overline{\nu}_e e$ may be obtained from Eq. (26.17) by replacing $g_{V,A}^{\nu e}$ by $g_{V,A}^{\nu e} + 1$, where the 1 is due to the charged-current contribution.

The SLAC polarized-electron experiment [29] measured the parity-violating asymmetry

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L}\,, \quad (26.19)$$

where $\sigma_{R,L}$ is the cross section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N \to e\text{X}$. In the quark parton model

$$\frac{A}{Q^2} = a_1 + a_2\,\frac{1-(1-y)^2}{1+(1-y)^2}\,, \quad (26.20)$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar target, one has, neglecting the s quark and antiquarks,

$$a_1 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(C_{1u} - \frac{1}{2}C_{1d}\right) \approx \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(-\frac{3}{4} + \frac{5}{3}\sin^2\theta_W\right) \quad (26.21a)$$

$$a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(C_{2u} - \frac{1}{2}C_{2d}\right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha}\left(\sin^2\theta_W - \frac{1}{4}\right) . \quad (26.21b)$$

Radiative corrections (other than m_t effects) lower the extracted value of $\sin^2\theta_W$ by $\sim$ 0.005.

Experiments measuring atomic parity violation [30] are now quite precise, and the uncertainties associated with atomic wave functions are relatively small (especially for cesium, for which the theoretical uncertainty is $\sim 1\%$ [31]). For heavy atoms one determines the "weak charge"

$$Q_W = -2\left[C_{1u}\,(2Z+N) + C_{1d}(Z+2N)\right]$$
$$\approx Z(1 - 4\sin^2\theta_W) - N . \quad (26.22)$$

Radiative corrections increase the extracted $\sin^2\theta_W$ by ~ 0.008.

The forward-backward asymmetry for $e^+e^- \to \ell\bar{\ell}$, $\ell = \mu$ or τ, is defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B} , \quad (26.23)$$

where $\sigma_F(\sigma_B)$ is the cross section for ℓ^- to travel forward (backward) with respect to the e^- direction. A_{FB} and R, the total cross section relative to pure QED, are given by

$$R = F_1 \quad (26.24)$$

$$A_{FB} = 3F_2/4F_1 , \quad (26.25)$$

where

$$F_1 = 1 - 2\chi_0\, g_V^e\, g_V^\ell\, \cos\delta_R + \chi_0^2\left(g_V^{e2} + g_A^{e2}\right)\left(g_V^{\ell 2} + g_A^{\ell 2}\right) \quad (26.26a)$$

$$F_2 = -2\chi_0\, g_A^e\, g_A^\ell\, \cos\delta_R + 4\chi_0^2\, g_A^e\, g_A^\ell\, g_V^e\, g_V^\ell , \quad (26.26b)$$

where

$$\tan\delta_R = \frac{M_Z\Gamma_Z}{M_Z^2 - s} \quad (26.27)$$

$$\chi_0 = \frac{G_F}{2\sqrt{2}\pi\alpha}\frac{sM_Z^2}{\left[(M_Z^2 - s)^2 + M_Z^2\Gamma_Z^2\right]^{1/2}} \quad (26.28)$$

and $\sqrt{s}$ is the CM energy. Eq. (26.26) is valid at tree level. If the data are radiatively corrected for QED effects (as described above), then the remaining electroweak corrections can be incorporated [32] (in an approximation adequate for existing PEP, PETRA, and TRISTAN data, which are well below the Z pole) by replacing χ_0 by $\chi(s) \equiv (1+\rho_t)\chi_0(s)\alpha/\widehat{\alpha}(s)$, where $\widehat{\alpha}(s)$ is the running QED coupling, and evaluating g_V in the $\overline{\rm MS}$ scheme. Formulas for $e^+e^- \to$ *hadrons* may be found in Ref. 33.

At LEP and SLC, there are high-precision measurements of various Z-pole observables. These include the Z mass and total width Γ_Z, and partial widths $\Gamma(f\bar{f})$ for $Z \to f\bar{f}$ for fermion f ($f = e$, μ, τ, hadrons, b, c, and ν). The data is consistent with lepton-family universality $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-) = \Gamma(\tau^+\tau^-)$, so one may work with an average width $\Gamma(\ell\bar{\ell})$. It is convenient to use the variables M_Z, Γ_Z, $R \equiv \Gamma(\text{had})/\Gamma(\ell\bar{\ell})$, $\sigma_{\rm had} \equiv 12\pi\Gamma(e^+e^-)\Gamma(\text{had})/M_Z^2\Gamma_Z^2$, $R_b \equiv \Gamma(b\bar{b})/\Gamma(\text{had})$, and $R_c \equiv \Gamma(c\bar{c})/\Gamma(\text{had})$, which are weakly correlated experimentally. ($\Gamma(\text{had})$ is the partial width into hadrons.) R is insensitive to m_t (except for $Z \to b\bar{b}$ vertex corrections) and is especially useful for constraining α_s. The width for invisible decays, $\Gamma(\text{inv}) = \Gamma_Z - 3\Gamma(\ell\bar{\ell}) - \Gamma(\text{had}) = 498.2 \pm 4.2$ MeV, can be used to determine the number of neutrino flavors lighter than $M_Z/2$, $N_\nu = \Gamma_{\rm inv}/\Gamma(\nu\bar{\nu}) \sim 2.98 \pm 0.03$.

There are also measurements of various asymmetries. These include the polarization or left-right asymmetry

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R} , \quad (26.29)$$

where $\sigma_L(\sigma_R)$ is the cross section for a left- (right)-handed incident electron. A_{LR} has been measured precisely by the SLD collaboration at SLC [34] and has the advantages of being extremely sensitive to $\sin^2\theta_W$ and insensitive to QED radiative corrections. Other asymmetries are the forward-backward asymmetries $A_{FB}^{(0,f)}$ for $f = e$, μ, τ, b, c ($A_{FB}^{(0,e)}$, $A_{FB}^{(0,\mu)}$, $A_{FB}^{(0,\tau)}$ are consistent with lepton-family universality, allowing an average value $A_{FB}^{(0,\ell)}$), the jet-charge asymmetry, the τ polarization P_τ, and its angular distribution. Further details, including references to the data from the LEP experiments (ALEPH, DELPHI, L3, OPAL) may be found in the Full Listings in the 'Note on the Z Boson.' At tree level and neglecting QED effects and terms of order $(\Gamma_Z/M_Z)^2$, one has

$$A_{FB}^{(0,f)} \approx \frac{3}{4}A_f\frac{A_e + P_e}{1 + P_eA_e} \quad (26.30)$$

$$A_{LR} \approx A_eP_e , \quad (26.31)$$

where P_e is the initial e^- polarization and

$$A_f \equiv \frac{2g_V^f\, g_A^f}{g_V^{f2} + g_A^{f2}} . \quad (26.32)$$

Similarly, A_τ is given by the negative total τ polarization, and A_e can be extracted from the angular distribution of the polarization.

It has become customary for the experimental groups to present corrected asymmetries A^0, in which photon exchange and γ-Z interference, QED corrections, and corrections for $\sqrt{s} \neq M_Z$ are removed from the data, leaving the pure electroweak asymmetries. Ignoring negligible electroweak boxes, these corrected asymmetries are expressed using effective tree-level expression *e.g.*, $A_{FB}^{(0,f)} = \frac{3}{4}\overline{A}_f\overline{A}_e$ (for $P_e = 0$) and $A_{LR}^0 = \overline{A}_e$, where

$$\overline{A}_f = \frac{2\overline{g}_V^f\,\overline{g}_A^f}{\overline{g}_V^{f2} + \overline{g}_A^{f2}} , \quad (26.33a)$$

and

$$\overline{g}_V^f = \sqrt{\rho_f}\,(t_{3L}^{(f)} - 2q_f\kappa_f\sin^2\theta_W) \quad (26.33b)$$

$$\overline{g}_A^f = \sqrt{\rho_f}\,t_{3L}^{(f)} . \quad (26.33c)$$

The electroweak-radiative corrections have been absorbed into corrections $\rho_f - 1$ and $\kappa_f - 1$, which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is give by $\rho_f \sim 1 + \rho_t$, $\kappa_f \sim \kappa_f^{os} \sim 1 + \rho_t/\tan^2\theta_W$, while in $\overline{\rm MS}$, $\rho_f \sim \widehat{\rho}$, $\kappa_f \equiv \widehat{\kappa}_f \sim 1$. In practice, additional bosonic loops, vertex corrections, *etc.*, must be included. For example, in the $\overline{\rm MS}$ scheme one has, for $(m_t, M_H) = (169, 300)$, $\rho_\ell = 1.0045$ and $\widehat{\kappa}_\ell = 1.0009$. It is convenient to define an effective angle $\overline{s}_f^2 \equiv \sin^2\overline{\theta}_{Wf} \equiv \widehat{\kappa}_f\widehat{s}_Z^2 = \kappa_f^{os}\,s_W^2$, in terms of which $\overline{g}_V^f$ and $\overline{g}_A^f$ are given by $\sqrt{\rho_f}$ times their tree-level formulae. Because $\overline{g}_V^\ell$ is very small, not only A_{LR}^0 $A_{FB}^{(0,\ell)}$, and P_τ^0, but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, and the jet-charge asymmetry are mainly sensitive to $\overline{s}_\ell^2$. One finds that $\widehat{\kappa}_f$ is almost independent of (m_t, M_H), so that

$$\overline{s}_\ell^2 \sim \widehat{s}_Z^2 + 0.0002 \quad (26.34)$$

using Ref. 15, or $\overline{s}_\ell^2 \sim \widehat{s}_Z^2 + 0.00028$ from Ref. 14 (the small difference is an indication of theoretical uncertainties from higher-order terms, *etc.*). In any case, the asymmetries determine values of $\overline{s}_\ell^2$ and $\widehat{s}_Z^2$ almost independent of m_t, while the κ's for the other schemes are m_t dependent.

26.3. *W* and *Z* decays

The partial decay width for gauge bosons to decay into massless fermions $f_1\overline{f}_2$ is

$$\Gamma(W^+ \to e^+\nu_e) = \frac{G_F M_W^3}{6\sqrt{2}\pi} \approx 227 \pm 1 \text{ MeV} \quad (26.35a)$$

$$\Gamma(W^+ \to u_i\overline{d}_i) = \frac{CG_F M_W^3}{6\sqrt{2}\pi} |V_{ij}|^2 \approx (707 \pm 3)\,|V_{ij}|^2 \text{ MeV} \quad (26.35b)$$

$$\Gamma(Z \to \psi_i\overline{\psi}_i) = \frac{CG_F M_Z^3}{6\sqrt{2}\pi}\left[g_V^{i2} + g_A^{i2}\right] \quad (26.35c)$$

$$\approx \begin{cases} 167.1 \pm 0.3 \text{ MeV } (\nu\overline{\nu}),\ 83.9 \pm 0.2 \text{ MeV } (e^+e^-), \\ 298.0 \pm 0.6 \text{ MeV } (u\overline{u}),\ 384.5 \pm 0.8 \text{ MeV } (d\overline{d}), \\ 375.2 \mp 0.4 \text{ MeV } (b\overline{b}). \end{cases}$$

For leptons $C = 1$, while for quarks $C = 3\Big(1+\alpha_s(M_V)/\pi + 1.409\alpha_s^2/\pi^2 - 12.77\alpha_s^3/\pi^3\Big)$, where the 3 is due to color and the factor in parentheses is a QCD correction. Corrections to Eq. (26.35) for massive fermions are given in Refs. 10 and 35 and the mass/Yukawa effects in the QCD corrections in Refs. [18,36]. Expressing the widths in terms of $G_F M_{W,Z}^3$ incorporates the bulk of the low-energy radiative corrections [10,35]. The $Z \to f\overline{f}$ widths have an additional QED correction $1 + 3\alpha\, q_f^2/4\pi$. The electroweak corrections are incorporated by replacing $g_{V,A}^{i2}$ by $\overline{g}_{V,A}^{i2}$. Hence, the widths are proportional to $\rho_i \sim 1 + \rho_t$. There is additional (negative) quadratic m_t dependence in the $Z \to b\overline{b}$ vertex corrections [37] which causes $\Gamma(b\overline{b})$ to decrease with m_t. The dominant effect is to multiply $\Gamma(b\overline{b})$ by the vertex correction $1 + \delta\rho_{b\overline{b}}$, where $\delta\rho_{b\overline{b}} \sim 10^{-2}(-\frac{1}{2}\frac{m_t^2}{M_Z^2} + \frac{1}{5})$. In practice, the corrections are included in ρ_b and κ_b.

For 3-fermion families the total widths are predicted to be

$$\Gamma_Z \approx 2.493 \pm 0.004 \text{ GeV} \quad (26.36)$$

$$\Gamma_W \approx 2.09 \pm 0.01 \text{ GeV} \ . \quad (26.37)$$

The numerical values for the widths assume $M_Z = 91.187 \pm 0.007$ GeV, $M_W = 80.29 \pm 0.11$ GeV, $\alpha_s = 0.120$, and $m_t = 169^{+16}_{-18}$ GeV, where the M_W, α_s, and m_t values are predicted by the global fits for $M_H = 300$ GeV. The uncertainties for Γ_W and Γ_Z are dominated by ΔM_W and Δm_t, respectively. The uncertainty in α_s, ± 0.007, introduces an additional uncertainty of 0.2% in the hadronic widths, corresponding to ± 4 MeV in Γ_Z.

These predictions are to be compared with the experimental results $\Gamma_Z = 2.490 \pm 0.007$ GeV and $\Gamma_W = 2.08 \pm 0.07$ GeV.

26.4. Experimental results

The values of the principal Z-pole observables are listed in Table 26.3, along with the Standard Model predictions for $M_Z = 91.187 \pm 0.007$, $m_t = 169^{+16}_{-18}$ GeV (for $M_H = 300$ GeV), 60 GeV $< M_H < 1$ TeV, and $\alpha_s = 0.120 \pm 0.007$. The values and predictions of M_W, M_W/M_Z, the Q_W for cesium [30,31], and recent results from deep inelastic and $\nu_e e$ scattering are also listed. The agreement is generally excellent, although $\Gamma_b = \Gamma(b\overline{b})/\Gamma(\text{had})$ is $\sim 1.8\sigma$ above the Standard Model prediction, and the left-right A_{LR}^0 is 2σ above the Standard Model prediction. There is also an experimental difference of $\sim 2\sigma$ between the SLD value of $A_e^0 = A_{LR}^0$ and the LEP value $A_{\ell\text{LEP}}^0 \sim 0.1434 \pm 0.0073$ obtained from $A_{FB}^{(0,\ell)}$, $A_e^0(P_\tau)$, $A_\tau^0(P_\tau)$ assuming lepton family universality. The observables in Table 26.3 (including correlations on the LEP observables), as well as all low-energy neutral-current data [9], are used in the global fits described below. The parameter $\sin^2\theta_W$ can be determined from the Z-pole observables and M_W, and from a variety of neutral-current processes spanning a very wide Q^2 range. The results [9], shown in Table 26.4, are in impressive agreement with each other, indicating the quantitative success of the Standard Model. The one discrepancy is the value $\widehat{s}_Z^2 = 0.2292 \pm 0.0010$ from A_{LR}^0 which is 2.4σ below the value (0.2319 ± 0.0005) from the global fit to all data and 2.8σ below the value 0.2323 ± 0.0005 obtained from all data other than A_{LR}^0.

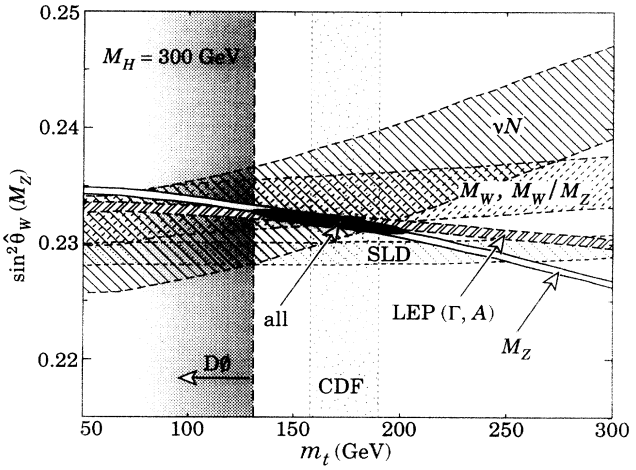

Figure 26.1: One-standard-deviation uncertainties in $\sin^2\widehat{\theta}_W$ as a function of m_t, the direct constraint $m_t > 131$ GeV, the CDF range 174 ± 16 GeV, and the 90% CL region in $\sin^2\widehat{\theta}_W - m_t$ allowed by all data, assuming $M_H = 300$ GeV.

The data allow a simultaneous determination of $\sin^2\theta_W$, m_t, and the strong coupling $\alpha_s(M_Z)$. The latter is determined mainly from Γ_Z and R, and is almost uncorrelated from the other variables. The global fit to all indirect data yields

$$\widehat{s}_Z^2 = 0.2319 \pm 0.0005 \pm 0.0002$$

$$m_t = 169^{+16+17}_{-18-20} \text{ GeV}$$

$$\alpha_s(M_Z) = 0.120 \pm 0.007 \pm 0.002\ , \quad (26.38)$$

where the central values are for a Higgs mass of 300 GeV, and the second error bars are for $M_H \to 1000(+)$ or $60(-)$ GeV. In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The $\widehat{s}_Z^2$ error is dominated by m_t, and $\widehat{s}_Z^2$ and m_t have a strong negative correlation of ~ -0.85. In the on-shell scheme one has $s_W^2 = 0.2247 \pm 0.0019$, the larger error due to the stronger sensitivity to m_t. The extracted value of α_s is based on a formula which has almost no theoretical uncertainty, and is in excellent agreement with the values 0.121 ± 0.006 from jet-event shapes, at the Z pole, and 0.116 ± 0.005 extracted from low-energy and jet data (see the section on Quantum Chromodynamics). Including the latter value as a separate constraint in the fits has negligible effect on $\sin^2\theta_W$ and m_t.

The value of m_t predicted by the precision data is in remarkable agreement with the value $m_t = 174 \pm 16$ GeV suggested by the CDF candidate top events. (The indirect prediction is for the pole mass, which should correspond approximately to the kinematic mass extracted from the CDF events.) One can carry out a combined fit of the indirect and direct (CDF) data, with the result $m_t = 172^{+11+8}_{-12-9}$ GeV, with little change in the $\sin^2\theta_W$ and α_s values. The results of fits to various combinations of the data are shown in Table 26.5 and the relation between $\widehat{s}_Z^2$ and m_t for various observables in Fig. 26.1.

The data indicate a preference for a small Higgs mass. This is because there is a strong correlation between the quadratic ρ_t terms and logarithmic M_H effects in all of the indirect data except the $Z \to b\overline{b}$ vertex. The latter favor a smaller m_t and therefore a smaller M_H. The difference in χ^2 for the global fit is $\Delta\chi^2 = \chi^2(M_H = 1000 \text{ GeV}) - \chi^2(M_H = 60 \text{ GeV}) = 2.9$. However, this sensitivity is reduced to $\Delta\chi^2 \sim 2.1$ when the direct CDF value of m_t is included. Hence, the data favor a small value of M_H, as in supersymmetric extensions of the Standard Model, and m_t on the lower side of the allowed range; but the effect is marginal statistically:

including the direct constraint $M_H \geq 60$ GeV, the best fit is for $M_H = 60$ GeV, with the weak limit $M_H < 840$ GeV at 90% CL. The value of $\widehat{s}^2_Z = 0.2319 \pm 0.0005$ is in striking agreement with the prediction 0.233 ± 0.003 of grand unified theories based on the minimal supersymmetric extension of the Standard Model, but disagrees with the prediction 0.210 ± 0.003 of nonsupersymmetric unified theories.

One can also determine the radiative correction parameters Δr: including the CDF data, one obtains $\Delta r = 0.040 \pm 0.004$ and $\Delta \widehat{r}_W = 0.068 \pm 0.003$, where the error includes m_t and M_H, in excellent agreement with the predictions 0.041 ± 0.007 and 0.0705 ± 0.0003.

Table 26.3: Principal LEP and other recent observables, compared with the Standard Model predictions for $M_Z = 91.187 \pm 0.007$ GeV, 60 GeV $< M_H <$ 1 TeV, the global best fit value $m_t = 169^{+16}_{-18}$ GeV (for $M_H = 300$ GeV), and $\alpha_s = 0.012 \pm 0.007$. The LEP averages [38] of the ALEPH, DELPHI, L3, and OPAL results include common systematic errors and correlations [38]. $\overline{s}_\ell(A^{(0,q)}_{FB})$ is the effective angle extracted from the quark-charge asymmetry. A^0_{LR} includes both 1992 and 1993 data. The more accurate 1993 run only yields 0.1656 ± 0.0076. In the fits, the values of $A^0_e(P_\tau)$ and A^0_{LR} are combined to give 0.161 ± 0.012, including a scale factor of 1.7. The values of $\Gamma(\ell\overline{\ell})$, Γ(had), and Γ(inv) are not independent of Γ_Z, R, and $\sigma_{\rm had}$. The M_W and M_W/M_Z values are from the PDG fit. In the fits shown here the (uncorrelated) values from the individual experiments are used. The two values of s^2_W from deep-inelastic scattering are from CCFR [25] and the global average, respectively. The $g^{\nu e}_{V,A}$ are from CHARM II [28]. The second error in Q_W (for cesium) is theoretical [31]. Older low-energy results are not listed but are included in the fits. In the Standard Model predictions, the first uncertainty is from M_Z and Δr, while the second is from m_t and M_H. The $\Delta\alpha_s = 0.007$ uncertainty leads to additional errors of 0.004 (Γ_Z), 0.05 (R), 0.04 (σ), 3.7 (Γ(had)).

Quantity	Value	Standard Model

SLD + M_Z	0.2294(9)(1) (0.2154 ± 0.0032)	—	238^{+20+17}_{-23-20}
Z pole (LEP + SLD)	0.2318(5)(2) (0.2241 ± 0.0021)	0.120(7)(2)	175^{+18+17}_{-19-20}

26.5. Deviations from the Standard Model

The Z pole, W mass, and neutral-current data can be used to search for and set limits on deviations from the Standard Model. For example, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin $> 1/2$ with significant vacuum expectation values. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters. It is convenient to take these as α, G_F, M_Z, and M_W, since M_W and M_Z are directly measurable. Then $\widehat{s}^2_Z$ and ρ_0 can be considered dependent parameters defined by

$$\widehat{s}^2_Z \equiv A^2_0/M^2_W(1 - \Delta\widehat{r}_W) \tag{26.39}$$

and

$$\rho_0 \equiv M^2_W/(M^2_Z \widehat{c}^2_Z \widehat{\rho}) \,. \tag{26.40}$$

Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect the radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (26.12)–(26.14), (26.28), and Γ_Z in

Eq. (26.35). (Also, the expression for M_Z is divided by $\sqrt{\rho_0}$; the M_W formula is unchanged.) There is now enough data to determine ρ_0, $\sin^2\theta_W$, m_t, and α_s simultaneously. In particular, R_b and the CDF events yield m_t independent of ρ_0, the asymmetries yield $\hat{s}^2_Z$, R gives α_s, and M_Z and the widths constrain ρ_0. From the global fit (including CDF),

$$\rho_0 = 1.0004 \pm 0.0022 \pm 0.002 \tag{26.41}$$

$$\hat{s}^2_Z = 0.2318 \pm 0.0005 \tag{26.42}$$

$$\alpha_s = 0.120 \pm 0.007 \tag{26.43}$$

$$m_t = 170^{+16}_{-15}\ , \tag{26.44}$$

where the second error on ρ_0 is from M_H (the other parameters are insensitive to M_H). This is in remarkable agreement with the Standard Model expectation $\rho_0 = 1$, and constrains any higher-dimensional Higgs representation to have vacuum expectation values of less than a few percent of those of the doublets. The allowed regions in the $\rho_0 - \hat{s}^2_Z$ plane are shown in Fig. 26.2.

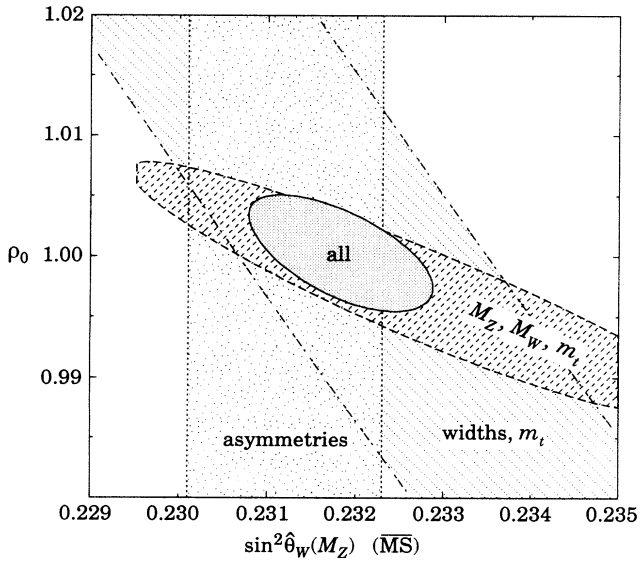

Figure 26.2: The allowed regions in $\sin^2\hat{\theta}_W - \rho_0$ at 90% CL. m_t is a free parameter and $M_H = 300$ GeV is assumed. (Varying M_H in the range 60–1000 GeV moves the contour down or up by 0.002.)

Most of the parameters relevant to ν-hadron, νe, e-hadron, and e^+e^- processes are determined uniquely and precisely from the data in "model independent" fits (*i.e.*, fits which allow for an arbitrary electroweak gauge theory). The values for the parameters defined in Eqs. (26.12)–(26.14) are given in Table 26.6 along with the predictions of the Standard Model. The agreement is excellent. The low-energy e^+e^- results are difficult to present in a model-independent way because Z-propagator effects are non-negligible at TRISTAN, PETRA, and PEP energies. However, assuming e-μ-τ universality, the lepton asymmetries imply [33] $4(g^e_A)^2 = 0.99 \pm 0.05$, in good agreement with the Standard Model prediction $\simeq 1$. The much more precisely measured Z-pole parameters in Table 26.3 are in excellent agreement with the Standard Model.

* Constraints on V are discussed in the section on the Cabibbo-Kobayashi-Maskawa mixing matrix.

Table 26.6: Values of the model-independent neutral-current parameters, compared with the Standard Model prediction using $M_Z = 91.187$ GeV for $m_t = 169^{+16}_{-18}$ GeV and $M_H = 300$ GeV. There is a second $g^{\nu e}_{V,A}$ solution, given approximately by $g^{\nu e}_V \leftrightarrow g^{\nu e}_A$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z. θ_i, $i = L$ or R, is defined as $\tan^{-1}[\epsilon_i(u)/\epsilon_i(d)]$.

Quantity	Experimental Value	Standard Model Prediction		Correlation
$\epsilon_L(u)$	0.332 ± 0.016	0.345 ± 0.001		
$\epsilon_L(d)$	-0.438 ± 0.012	-0.429 ± 0.001		non-
$\epsilon_R(u)$	-0.178 ± 0.013	-0.155		Gaussian
$\epsilon_R(d)$	$-0.026\ ^{+0.075}_{-0.048}$	0.078		
g^2_L	0.3017 ± 0.0033	0.303 ± 0.001		
g^2_R	0.0326 ± 0.0033	0.030		small
θ_L	2.50 ± 0.035	2.46		
θ_R	$4.58\ ^{+0.46}_{-0.28}$	5.18		
$g^{\nu e}_A$	-0.506 ± 0.015	-0.506 ± 0.001		-0.04
$g^{\nu e}_V$	-0.039 ± 0.017	-0.037 ± 0.001		
C_{1u}	-0.214 ± 0.046	-0.189 ± 0.001	-0.995	-0.79
C_{1d}	0.359 ± 0.041	0.341 ± 0.002		0.79
$C_{2u} - \frac{1}{2}C_{2d}$	-0.04 ± 0.13	-0.051 ± 0.002

27. CONSTRAINTS ON NEW PHYSICS FROM ELECTROWEAK ANALYSES

This section prepared May 1994 by P. Langacker and J. Erler.

Precision electroweak experiments are sensitive to loop effects, allowing a prediction of the top quark mass m_t, constraints on the Higgs mass M_H, and a search for certain types of new physics that have not been directly detected. This article will mainly discuss m_t, M_H, and the effects of exotic particles with masses large compared to M_Z on the gauge boson self-energies. Brief remarks are made on new physics which is not of this type. The effects of m_t and M_H on the radiative corrections are treated exactly to one-loop order. This can in principle be done for other types of new physics, but this necessitates a case-by-case discussion. Instead, the article will discuss in detail only the constraints on particles with heavy masses $M_{\rm new} \gg M_Z$ in an expansion in $M_Z/M_{\rm new}$. In this case, most of the effects on precision measurements can be described by three gauge self-energy parameters S, T, and U, and a $Zb\bar{b}$ vertex correction parameter γ_b.

A large value of $|m_t - m_b|$ breaks vector SU(2) symmetry and significantly affects many precision electroweak observables. The major sensitivity for processes involving light external fermions is through t- and b-quark loop contributions to the W and Z self-energies [1]. Most of the shift in M_W is absorbed into the measured value of the Fermi constant G_F, while the prediction for M_Z,

$$M_Z = \frac{M_W}{\widehat{\rho}^{1/2}\widehat{c}_Z} , \tag{27.1}$$

decreases rapidly for large m_t. In Eq. (27.1) $\widehat{\rho} \simeq 1 + \rho_t$, where

$$\rho_t = \frac{3G_F m_t^2}{8\sqrt{2}\pi^2} \sim 0.0031 \left(\frac{m_t}{100\ {\rm GeV}}\right)^2 , \tag{27.2}$$

and $\widehat{c}_Z = \cos\widehat{\theta}_W(M_Z)$, the cosine of the weak angle in the $\overline{\rm MS}$ scheme evaluated at M_Z [2]. In addition to M_Z itself, neutral current amplitudes and the coefficient of $G_F M_Z^3$ in the expression for Γ_Z are multiplied by $\widehat{\rho}$. There is additional logarithmic m_t dependence in these quantities and in M_W. Vertex and box diagrams also introduce large (quadratic) m_t dependence, which is especially important in quantities involving external b quarks (in order to avoid mixing angle suppressions), such as in the $Z \to b\bar{b}$ partial width or in $B - \overline{B}$ mixing. Finally, in the on-shell renormalization scheme, significant but somewhat artificial m_t dependence is introduced into Z vertices through the definition [2] $s_W^2 \equiv 1 - M_W^2/M_Z^2$.

The CDF collaboration has recently presented [3] a number of candidate top quark events, with a mass $m_t = 174 \pm 16$ GeV. However, they have not yet claimed a definite discovery. Therefore, the indirect constraints on m_t from precision experiments will first be summarized, and then the results when the CDF value is combined with the indirect constraints.

As discussed in the section on the Standard Model of Electroweak Interactions (see especially Figure 1 of that section), the consistency of the various observables allows a prediction for m_t. A global fit to all data (see Table 26.5 of the Standard Model Section) yields

$$m_t = 169^{+16+17}_{-18-20}\ {\rm GeV} , \tag{27.3}$$

where the central value is for a Higgs mass $M_H = 300$ GeV and the second uncertainty is from varying M_H in the range 60 GeV (−) to 1000 GeV (+). One can also use the indirect data to set upper limits on m_t. Taking the DØ lower limit $m_t > 131$ GeV [4] into account, one finds $m_t < 205\,(210)$ GeV at 90 (95)% CL for $M_H \leq 1000$ GeV.

The upper limit on m_t is unchanged or strengthened in the presence of many types of new physics. For example, nondegenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W. A nondegenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a positive contribution to ρ_t of [1]

$$\frac{CG_F}{8\sqrt{2}\pi^2}\Delta m^2 , \tag{27.4}$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2 m_2^2}{m_1^2 - m_2^2}\ln\frac{m_1}{m_2} \geq (m_1 - m_2)^2 , \tag{27.5}$$

and $C = 1$ (3) for color singlets (triplets). Thus, to a good first approximation (*i.e.*, except for $\Gamma(Z \to b\bar{b})$ and logarithmic effects) the 90% CL upper limit $m_t < 205$ GeV in the Standard Model can be reinterpreted as

$$m_t^2 + \sum_i \frac{C_i}{3}\Delta m_i^2 < (205\ {\rm GeV})^2 , \tag{27.6}$$

where the sum includes fourth-family quark or lepton doublets, $\binom{t'}{b'}$ or $\binom{E^0}{E^-}$, and scalar doublets such as $\binom{\tilde{t}}{\tilde{b}}$ in supersymmetry (in the absence of $L - R$ mixing). Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally strengthen the m_t limit [5]. Additional Higgs doublets which participate in spontaneous symmetry breaking [6], heavy lepton doublets involving Majorana neutrinos [7], and the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) can weaken the limits on m_t, though the effect is usually small for reasonable parameter ranges. The only known way to significantly weaken the limits is to allow for the presence of Higgs triplets (or higher-dimensional representations), whose vacuum expectation values can cancel all of the quadratic m_t dependence except for the $b\bar{b}$ vertex. Even in that case one has an upper limit of 220 (237) GeV at 90 (95)% CL, mainly from $R_b \equiv \Gamma(Z \to b\bar{b})/\Gamma(Z \to {\rm had})$ [2,8].

All of these constraints become much tighter when one incorporates the mass $m_t = 174 \pm 16$ GeV of the CDF candidate events [3], which is remarkably consistent with the prediction in Eq. (27.3). (The indirect prediction is for the pole mass, which should approximately coincide with the kinematic mass determined by CDF.) The joint fit to indirect and direct data yields [2] $m_t = 172^{+11+8}_{-12-9}$ GeV, again with the central value for $M_H = 300$ GeV.

As discussed in Ref. 2, the combination of indirect data with the CDF value for m_t allows stringent limits on new physics. In particular, many extensions of the Standard Model are described by the ρ_0 parameter:

$$\rho_0 \equiv M_W^2/(M_Z^2\,\widehat{c}_Z^2\,\widehat{\rho}) , \tag{27.7}$$

which describes new sources of SU(2) breaking that cannot be accounted for by Higgs doublets or m_t effects. It has previously been difficult to distinguish ρ_0 from $\widehat{\rho} \simeq 1 + \rho_t$ experimentally, though some separation could be done utilizing R_b [8]. Using the CDF m_t value as an independent constraint, however, one can calculate $\widehat{\rho}$ and thus obtain the precise value [2] $\rho_0 = 1.0004 \pm 0.0022 \pm 0.002$, where the second error is from M_H. In Ref. 2, this result was used to constrain the vacuum expectation values of higher-dimensional Higgs representations. It can also be used to constrain Δm^2 from nondegenerate SU(2) multiplets, as defined in Eq. (27.5). That is, in the presence of such multiplets, one has

$$\frac{3G_F}{8\sqrt{2}\pi^2}\sum_i \frac{C_i}{3}\Delta m_i^2 = \rho_0 - 1 , \tag{27.8}$$

implying

$$\sum_i \frac{C_i}{3}\Delta m_i^2 < (95\ {\rm GeV})^2 ,\ (111\ {\rm GeV})^2 ,\ (128\ {\rm GeV})^2 \tag{27.9}$$

for $M_H = 60$, 300, or 1000 GeV at 90% CL.

As discussed in the Standard Model of Electroweak Interactions section, the indirect data exhibit a moderate preference for a smaller Higgs mass. The best fit to m_t as a function of M_H is roughly

$$m_t \sim 169^{+16}_{-18} + 13\ \ln\left(\frac{M_H}{300\ {\rm GeV}}\right) \tag{27.10}$$

without the direct CDF constraint or

$$m_t \sim 172^{+11}_{-12} + 6\ \ln\left(\frac{M_H}{300\ {\rm GeV}}\right) \tag{27.11}$$

with it. The χ^2 for $M_H = 60$ GeV is lower by 2.9 (2.1) than that for $M_H = 1000$ GeV for the two cases, implying $M_H \lesssim 840$ GeV at 90% CL. While not compelling statistically, this result is consistent with the minimal supersymmetric extension of the Standard Model, which acts much like the Standard Model with a light Higgs as far as precision experiments are concerned. Of course, the conclusions for M_H could be invalidated if other new physics modifies the precision observables significantly.

A number of authors [9–14] have considered the general effects on neutral current and Z and W-pole observables of various types of heavy (*i.e.*, $M > M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to nondegenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators. The effects of one degenerate chiral doublet are small, but in technicolor theories there may be many chiral doublets and therefore significant effects [9].

All such effects can be described by just three parameters, S, T, and U. T is proportional to the difference between the W and Z self-energies at $Q^2 = 0$ (*i.e.*, vector SU(2)-breaking), while S ($S + U$) is associated with the difference between the Z (W) self-energy at $Q^2 = M_{Z,W}^2$ and $Q^2 = 0$ (axial SU(2)-breaking). In the $\overline{\rm MS}$ scheme [10]

$$\alpha T \equiv \frac{\Pi_{WW}^{\rm new}(0)}{M_W^2} - \frac{\Pi_{ZZ}^{\rm new}(0)}{M_Z^2}$$

$$\frac{\alpha}{4\hat{s}_Z^2\hat{c}_Z^2} S \equiv \frac{\Pi_{ZZ}^{\rm new}(M_Z^2) - \Pi_{ZZ}^{\rm new}(0)}{M_Z^2}$$

$$\frac{\alpha}{4\hat{s}_Z^2}(S+U) \equiv \frac{\Pi_{WW}^{\rm new}(M_W^2) - \Pi_{WW}^{\rm new}(0)}{M_W^2} \ , \qquad (27.12)$$

where $\Pi_{WW}^{\rm new}$ and $\Pi_{ZZ}^{\rm new}$ are respectively the contributions of the new physics to the W and Z self-energies, $\hat{s}_Z^2 = \sin^2\hat{\theta}_W(M_Z)$, $\hat{c}_Z^2 = 1 - \hat{s}_Z^2$, and α is the running coupling evaluated at M_Z. S, T, and U are defined with a factor of α removed, so that they are expected to be of order unity in the presence of new physics. S, T, and U are related to other parameters ($\hat{\epsilon}_i$, h_i, S_i) defined in [10–12] by

$$T = h_V = \hat{\epsilon}_1/\alpha$$

$$S = h_{AZ} = S_Z = 4\hat{s}_Z^2\hat{\epsilon}_3/\alpha$$

$$U = h_{AW} - h_{AZ} = S_W - S_Z = -4\hat{s}_Z^2\hat{\epsilon}_2/\alpha \ . \qquad (27.13)$$

A heavy nondegenerate multiplet of fermions or scalars contributes to T as

$$\rho_0 = \frac{1}{1-\alpha T} \simeq 1 + \alpha T \ , \qquad (27.14)$$

where ρ_0 is given in Eq. (27.8). If there are non-doublet Higgs representations, their vacuum expectation values also contribute to ρ_0. The effects of such nonstandard Higgs representations cannot be separated from heavy nondegenerate multiplets unless the new physics has other consequences, such as vertex corrections.

A multiplet of heavy degenerate chiral fermions yields

$$S = C\sum_i \Big(t_{3L}(i) - t_{3R}(i)\Big)^2/3\pi \ , \qquad (27.15)$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left- (right-) handed component of fermion i and C is the number of colors. For example, a heavy degenerate family would contribute $2/3\pi$ to S. In technicolor models with QCD-like dynamics, one expects [9] $S \sim 0.45$ for an isodoublet of technifermions, assuming $N_{TC} = 4$ technicolors, while $S \sim 1.62$ for a full technigeneration with $N_{TC} = 4$; T is harder to estimate because it is model dependent. In these examples one has $S \geq 0$. However, it is possible to find situations in which $S < 0$ [15]. In particular, these estimates do not apply to models of walking technicolor, for which S can be smaller or even negative [16]. Supersymmetric extensions of the Standard Model generally give very small effects [17]. Most simple types of new physics yield $U = 0$, although there are counter-examples, such as the effects of anomalous triple-gauge vertices [12].

It is also possible to parametrize the effects of large $m_t \gg M_Z$ (except for the $b\bar{b}$ vertex) or $M_H \gg M_Z$ in terms of S, T, and U. If one takes $m_t = m_t^{\rm ref}, M_H = M_H^{\rm ref}$ as a reference point, then other values of m_t and M_H can be expressed for large m_t, M_H as [11]

$$\Delta T = \frac{\rho_t(m_t) - \rho_t(m_t^{\rm ref})}{\alpha} - \frac{3G_F}{4\sqrt{2}\alpha\pi^2}(M_Z^2 - M_W^2)\ln(M_H/M_H^{\rm ref})$$

$$\Delta S = c_S \ln(m_t/m_t^{\rm ref}) + \frac{1}{6\pi}\ln(M_H/M_H^{\rm ref})$$

$$\Delta U = c_U \ln(m_t/m_t^{\rm ref}) \ , \qquad (27.16)$$

where the coefficients c_S and c_U depend on the renormalization scheme. Various authors use different reference values for m_t and M_H when determining S, T, and U from the data. In the following $M_H^{\rm ref} = 300$ GeV and the global best fit value $m_t^{\rm ref} = 169$ GeV will be used when the CDF constraint is not imposed. The allowed ranges of the parameters will then represent both the effects of new physics and of values of m_t and M_H different from the reference values, *i.e.*, $S = S_{\rm new} + \Delta S$, $T = T_{\rm new} + \Delta T$, $U = U_{\rm new} + \Delta U$. For later use, note that $\Delta S = \Delta S_t + \Delta S_{\rm Higgs}$ and similarly for ΔT.

The Standard Model expressions for observables are replaced by

$$M_Z^2 = M_{Z0}^2 \frac{1-\alpha T}{\rho_0} \frac{1}{1 - G_F M_{Z0}^2 S/2\sqrt{2}\pi}$$

$$M_W^2 = M_{W0}^2 \frac{1}{1 - G_F M_{W0}^2 (S+U)/2\sqrt{2}\pi} \ , \qquad (27.17)$$

where M_{Z0} and M_{W0} are the Standard Model expressions in the $\overline{\rm MS}$ scheme. Furthermore,

$$\Gamma_Z = \frac{\rho_0}{1-\alpha T} M_Z^3 \beta_Z$$

$$\Gamma_W = M_W^3 \beta_W$$

$$A_i = \frac{\rho_0}{1-\alpha T} A_{i0} \ , \qquad (27.18)$$

where β_Z and β_W are the Standard Model expressions for the reduced widths Γ_{Z0}/M_{Z0}^3 and Γ_{W0}/M_{W0}^3, M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral current amplitude (in the Standard Model).

The $Z \to b\bar{b}$ vertex is sensitive to certain types of new physics which primarily couple to heavy families [18,19]. It is useful to introduce an additional parameter γ_b by [20]

$$\Gamma(Z \to b\bar{b}) = \Gamma^0(Z \to b\bar{b})(1 + \gamma_b) \ , \qquad (27.19)$$

where Γ^0 is the Standard Model expression (or the expression modified by S, T, U, and ρ_0). Experimentally, $R_b \equiv \Gamma(Z \to b\bar{b})/\Gamma({\rm had})$ is about 1.8σ above the Standard Model expectations, favoring a positive γ_b. Extended technicolor models generally yield negative values of γ_b of a few percent [18], while supersymmetry can yield (typically small) contributions of either sign [19].

The indirect data allow a simultaneous determination of $\hat{s}_Z^2$ (*e.g.*, from the Z-pole asymmetries), S (from M_Z), U (from M_W), T (*e.g.*, from the Z-decay widths), α_s (from $\Gamma(Z \to {\rm had})/\Gamma(\ell\bar{\ell})$, and γ_b (from R_b) with little correlation. For the reference values for m_t and M_H, one obtains

$$S = -0.42 \pm 0.36$$

$$T = -0.37 \pm 0.39$$

$$U = -1.3 \ \pm 1.3$$

$$\gamma_b = \ 0.032 \pm 0.016 \ , \qquad (27.20a)$$

and $\widehat{s}^2_Z = 0.2311 \pm 0.0007$, $\alpha_s = 0.099 \pm 0.013$. Combining with the CDF direct value of m_t, one does not need to introduce a reference value for m_t. That is, one can determine $S_{\rm new}$, $T_{\rm new}$, $U_{\rm new}$, and γ_b directly, in a simultaneous fit with $\widehat{s}^2_Z$, α_s, and m_t. One obtains

$$S_{\rm new} = -0.42 \pm 0.36^{-0.08}_{+0.17}$$

$$T_{\rm new} = -0.35 \pm 0.44^{+0.18}_{-0.11}$$

$$U_{\rm new} = -1.3 \ \pm 1.3$$

$$\gamma_b = \ 0.032 \pm 0.017 \ , \qquad (27.20b)$$

and the allowed region in $S'_{\rm new}$–$T'_{\rm new}$ is shown in Figure 1. ($S'_{\rm new}$ includes the M_H dependence explicitly, $S'_{\rm new} \equiv S_{\rm new} + \Delta S_{\rm Higgs}$, and similarly for $T'_{\rm new}$, see Eq. (27.16).) The values in Eq. (27.20*b*) are almost identical to those in Eq. (27.20*a*) except for a small increase in the errors due to the variation of m_t around the best fit value 175 ± 16. The second error bars represent the uncertainty due to M_H ranging from the reference value of 300 GeV to 1000 (upper) or 60 (lower) GeV. From Eq. (27.20*b*) one obtains $S_{\rm new} < 0.09\,(+0.23)$, and $T < 0.27\,(0.43)$ at 90 (95)% CL. If one requires the constraint $S_{\rm new} \geq 0$ then (as in QCD-like technicolor models) $S_{\rm new} < 0.38\,(0.46)$. Allowing arbitrary $S_{\rm new}$, only one heavy generation of ordinary fermions is allowed at 95% CL. The favored value of $S_{\rm new}$ is problematic for technicolor models with many techni-doublets and QCD-like dynamics, as is the value of γ_b. Although $S_{\rm new}$ is consistent with zero, the electroweak asymmetries, especially the SLD left-right asymmetry, favor $S_{\rm new} < 0$. The simplest origin of $S_{\rm new} < 0$ would probably be an additional heavy Z' boson [5], which could mimic $S_{\rm new} < 0$.

There is no simple parametrization that is powerful enough to describe the effects of every type of new physics on every possible observable. The S, T, and U formalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons or mixing with exotic fermions cannot be fully parametrized in the S, T, and U framework. It is convenient to treat these types of new physics by parametrizations that are specialized to that particular class of theories (*e.g.*, extra Z' bosons), or to consider specific models (which might contain, *e.g.*, Z' bosons and exotic fermions with correlated parameters). An alternate formalism [21] defines parameters, ϵ_1, ϵ_2, ϵ_3, ϵ_b in terms of the specific observables M_W/M_Z, the leptonic Z width $\Gamma_{\ell\ell}$, the forward-backward asymmetry [2] at the Z pole, $A_{FB}^{(0,\ell)}$, and R_b. The definitions coincide with those for $\widehat{\epsilon}_i$ in Eqs. (27.12) and (27.13) for physics which affects gauge self-energies only, but the ϵ's now parametrize arbitrary types of new physics and can also incorporate all of the effects of m_t and M_H on the four basic observables. However, the ϵ's are not related to other observables unless additional model-dependent assumptions are made. Another approach [22] parametrizes new physics in terms of gauge-invariant sets of operators. It is especially powerful in studying the effects of new physics on nonabelian gauge vertices. The most general approach introduces deviation vectors [24]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its Standard Model prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

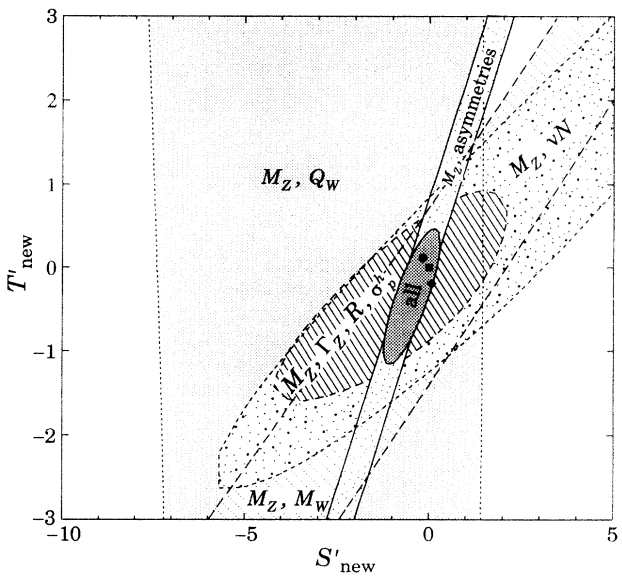

Figure 27.1: 90% CL limits on $S'_{\rm new}$ and $T'_{\rm new}$ from various inputs. $S'_{\rm new}$ and $T'_{\rm new}$ have the m_t dependence removed (it is fit separately), but contain the small M_H dependence. In the Standard Model, one expects $S'_{\rm new} = T'_{\rm new} = 0$ for $M_H = 300$ GeV (indicated by a box). The expected values for $M_H = 60$ GeV (circle) and 1000 GeV (diamond) are also indicated. The fit to M_W and M_Z assumes $U = 0$, while U is arbitrary in the other fits.

28. THE CABIBBO-KOBAYASHI-MASKAWA MIXING MATRIX

Updated 1993 by F.J. Gilman, K. Kleinknecht, and B. Renk.

In the Standard Model with SU(2) × U(1) as the gauge group of electroweak interactions, both the quarks and leptons are assigned to be left-handed doublets and right-handed singlets. The quark mass eigenstates are not the same as the weak eigenstates, and the matrix relating these bases was defined for six quarks and given an explicit parametrization by Kobayashi and Maskawa [1] in 1973. It generalizes the four-quark case, where the matrix is parametrized by a single angle, the Cabibbo angle [2].

By convention, the three charge 2/3 quarks (u, c, and t) are unmixed, and all the mixing is expressed in terms of a 3 × 3 unitary matrix V operating on the charge $-1/3$ quarks (d, s, b):

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} . \tag{28.1}$$

The values of individual matrix elements can in principle all be determined from weak decays of the relevant quarks, or, in some cases, from deep inelastic neutrino scattering. Using the constraints discussed below together with unitarity, and assuming only three generations, the 90% confidence limits on the magnitude of the elements of the complete matrix are:

$$\begin{pmatrix} 0.9747 \text{ to } 0.9759 & 0.218 \text{ to } 0.224 & 0.002 \text{ to } 0.005 \\ 0.218 \text{ to } 0.224 & 0.9738 \text{ to } 0.9752 & 0.032 \text{ to } 0.048 \\ 0.004 \text{ to } 0.015 & 0.030 \text{ to } 0.048 & 0.9988 \text{ to } 0.9995 \end{pmatrix} . \tag{28.2}$$

The ranges shown are for the individual matrix elements. The constraints of unitarity connect different elements, so choosing a specific value for one element restricts the range of the others.

There are several parametrizations of the Cabibbo-Kobayashi-Maskawa matrix. In view of the need for a "standard" parametrization in the literature, we advocate:

$$V = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{13}} \\ -s_{12}c_{23}-c_{12}s_{23}s_{13}e^{i\delta_{13}} & c_{12}c_{23}-s_{12}s_{23}s_{13}e^{i\delta_{13}} & s_{23}c_{13} \\ s_{12}s_{23}-c_{12}c_{23}s_{13}e^{i\delta_{13}} & -c_{12}s_{23}-s_{12}c_{23}s_{13}e^{i\delta_{13}} & c_{23}c_{13} \end{pmatrix} \tag{28.3}$$

proposed by Chau and Keung [3]. The choice of rotation angles follows earlier work of Maiani [4], and the placement of the phase follows that of Wolfenstein [5]. The notation used is that of Harari and Leurer [6] who, along with Fritzsch and Plankl [7], proposed this parametrization as a particular case of a form generalizable to an arbitrary number of "generations." The general form was also put forward by Botella and Chau [8]. Here $c_{ij} = \cos\theta_{ij}$ and $s_{ij} = \sin\theta_{ij}$, with i and j being "generation" labels, $\{i, j = 1, 2, 3\}$. In the limit $\theta_{23} = \theta_{13} = 0$ the third generation decouples, and the situation reduces to the usual Cabibbo mixing of the first two generations with θ_{12} identified with the Cabibbo angle [2]. The real angles θ_{12}, θ_{23}, θ_{13} can all be made to lie in the first quadrant by an appropriate redefinition of quark field phases. Then all s_{ij} and c_{ij} are positive, $|V_{us}| = s_{12}c_{13}$, $|V_{ub}| = s_{13}$, and $|V_{cb}| = s_{23}c_{13}$. As c_{13} is known to deviate from unity only in the fifth decimal place, $|V_{us}| = s_{12}$, $|V_{ub}| = s_{13}$, and $|V_{cb}| = s_{23}$ to an excellent approximation. The phase δ_{13} lies in the range $0 \le \delta_{13} < 2\pi$, with non-zero values generally breaking CP invariance for the weak interactions. The generalization to the n generation case contains $n(n-1)/2$ angles and $(n-1)(n-2)/2$ phases [6,7,8]. The range of matrix elements in Eq. (28.2) corresponds to 90% CL limits on the angles of $s_{12} = 0.218$ to 0.224, $s_{23} = 0.032$ to 0.048, and $s_{13} = 0.002$ to 0.005.

Kobayashi and Maskawa [1] originally chose a parametrization involving the four angles, θ_1, θ_2, θ_3, δ:

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} c_1 & -s_1c_3 & -s_1s_3 \\ s_1c_2 & c_1c_2c_3-s_2s_3e^{i\delta} & c_1c_2s_3+s_2c_3e^{i\delta} \\ s_1s_2 & c_1s_2c_3+c_2s_3e^{i\delta} & c_1s_2s_3-c_2c_3e^{i\delta} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} , \tag{28.4}$$

where $c_i = \cos\theta_i$ and $s_i = \sin\theta_i$ for $i = 1, 2, 3$. In the limit $\theta_2 = \theta_3 = 0$, this reduces to the usual Cabibbo mixing with θ_1 identified (up to a sign) with the Cabibbo angle [2]. Slightly different forms of the Kobayashi-Maskawa parametrization are found in the literature. The CKM matrix used in the 1982 *Review of Particle Properties* is obtained by letting $s_1 \to -s_1$ and $\delta \to \delta + \pi$ in the matrix given above. An alternative is to change Eq. (28.4) by $s_1 \to -s_1$ but leave δ unchanged. With this change in s_1, the angle θ_1 becomes the usual Cabibbo angle, with the "correct" sign (*i.e.* $d' = d\cos\theta_1 + s\sin\theta_1$) in the limit $\theta_2 = \theta_3 = 0$. The angles θ_1, θ_2, θ_3 can, as before, all be taken to lie in the first quadrant by adjusting quark field phases. Since all these parametrizations are referred to as "the" Kobayashi-Maskawa form, some care about which one is being used is needed when the quadrant in which δ lies is under discussion.

Other parametrizations, mentioned above, are due to Maiani [4] and to Wolfenstein [5]. The latter emphasizes the relative sizes of the matrix elements by expressing them in powers of the Cabibbo angle. Still other parametrizations [9] have come into the literature in connection with attempts to define "maximal CP violation". No physics can depend on which of the above parametrizations (or any other) is used as long as a single one is used consistently and care is taken to be sure that no other choice of phases is in conflict.

Our present knowledge of the matrix elements comes from the following sources:

(1) Nuclear beta decay, when compared to muon decay, gives [10–13]

$$|V_{ud}| = 0.9744 \pm 0.0010 . \tag{28.5}$$

This includes refinements in the analysis of the radiative corrections, especially the order $Z\alpha^2$ effects, which have brought the ft-values from low and high Z Fermi transitions into good agreement.

(2) Analysis of K_{e3} decays yields [14]

$$|V_{us}| = 0.2196 \pm 0.0023 . \tag{28.6}$$

(The notation K^+_{e3} refers to $K^+ \to \pi^0 e^+ \nu_e$ and K^0_{e3} refers to $K^0_L \to \pi^\pm e^\mp \nu_e$.) The isospin violation between K^+_{e3} and K^0_{e3} decays has been taken into account, bringing the values of $|V_{us}|$ extracted from these two decays into agreement at the 1% level of accuracy. The analysis of hyperon decay data has larger theoretical uncertainties because of first order SU(3) symmetry breaking effects in the axial-vector couplings, but due account of symmetry breaking [15] applied to the WA2 data [16] gives a corrected value [17] of 0.222 ± 0.003. We average these two results to obtain:

$$|V_{us}| = 0.2205 \pm 0.0018 . \tag{28.7}$$

(3) The magnitude of $|V_{cd}|$ may be deduced from neutrino and antineutrino production of charm off valence d quarks. The dimuon production cross sections of the CDHS group [18] yield $\overline{B}_c |V_{cd}|^2 = 0.41 \pm 0.07 \times 10^{-2}$, where $\overline{B}_c$ is the semileptonic branching fraction of the charmed hadrons produced. The corresponding value from a recent Tevatron experiment [19] is $\overline{B}_c |V_{cd}|^2 = 0.534^{+0.052}_{-0.078} \times 10^{-2}$. Averaging these two results gives $\overline{B}_c |V_{cd}|^2 = 0.47 \pm 0.05 \times 10^{-2}$. Supplementing this with measurements of the semileptonic branching fractions of charmed mesons [20], weighted by a production ratio of $D^0/D^+ = (60 \pm 10)/(40 \mp 10)$, to give $\overline{B}_c = 0.113 \pm 0.015$, yields

$$|V_{cd}| = 0.204 \pm 0.017 \tag{28.8}$$

(4) Values of $|V_{cs}|$ from neutrino production of charm are dependent on assumptions about the strange quark density in the parton-sea. The most conservative assumption, that the strange-quark sea does not exceed the value corresponding to an SU(3) symmetric sea, leads to a lower bound [18], $|V_{cs}| > 0.59$. It is more advantageous to proceed analogously to the method used for extracting $|V_{us}|$ from K_{e3} decay; namely, we compare the experimental value for the width of D_{e3} decay with the expression [21] that follows from the standard weak interaction amplitude:

$$\Gamma(D \to \overline{K} e^+ \nu_e) = |f^D_+(0)|^2 \, |V_{cs}|^2 \, (1.54 \times 10^{11} \text{ s}^{-1}) . \tag{28.9}$$

Here $f_+^D(q^2)$, with $q = p_D - p_K$, is the form factor relevant to D_{e3} decay; its variation has been taken into account with the parametrization $f_+^D(t)/f_+^D(0) = M^2/(M^2 - t)$ and $M = 2.1$ GeV/c^2, a form and mass consistent with Mark III and E691 measurements [22,23]. Combining data on branching ratios for $D_{\ell 3}$ decays from Mark III, E687, E691, and CLEO experiments [22–24] with accurate values [25] for τ_{D^+} and τ_{D^0}, gives the value $(0.762 \pm 0.055) \times 10^{11}$ s^{-1} for $\Gamma(D \to \overline{K} e^+ \nu_e)$. Therefore

$$|f_+^D(0)|^2 \, |V_{cs}|^2 = 0.495 \pm 0.036 \; . \tag{28.10}$$

A very conservative assumption is that $|f_+^D(0)| < 1$, from which it follows that $|V_{cs}| > 0.62$. Calculations of the form factor either performed [26,27] directly at $q^2 = 0$, or done [28] at the maximum value of $q^2 = (m_D - m_K)^2$ and interpreted at $q^2 = 0$ using the measured q^2 dependence, yield $f_+^D(0) = 0.7 \pm 0.1$. It follows that

$$|V_{cs}| = 1.01 \pm 0.18 \; . \tag{28.11}$$

The constraint of unitarity when there are only three generations gives a much tighter bound (see below).

(5) The ratio $|V_{ub}/V_{cb}|$ can be obtained from the semileptonic decay of B mesons produced on the $\Upsilon(4S)$ $b\overline{b}$ resonance by measuring the lepton energy spectrum above the endpoint of the $b \to c\ell\nu$ spectrum. There the $b \to u\ell\nu$ decay rate can be obtained by subtracting the background from nonresonant e^+e^- reactions. This continuum background is determined from auxiliary measurements off the $\Upsilon(4S)$. Both the CLEO [29] and ARGUS [30] collaborations have reported evidence for $b \to u$ transitions in semileptonic B decays. The interpretation of the result in terms of $|V_{ub}/V_{cb}|$ depends fairly strongly on the theoretical model used to generate the lepton energy spectrum, especially for $b \to u$ transitions [27,28,31]. Combining the experimental and theoretical uncertainties, we quote

$$|V_{ub}/V_{cb}| = 0.08 \pm 0.02 \; . \tag{28.12}$$

(6) The magnitude of V_{cb} itself can be determined if the measured semileptonic bottom hadron partial width is assumed to be that of a b quark decaying through the usual $V - A$ interaction:

$$\Gamma(b \to c\ell\overline{\nu}_\ell) = \frac{\mathrm{B}(b \to c\ell\overline{\nu}_\ell)}{\tau_b} = \frac{G_F^2 \, m_b^5}{192\pi^3} F(m_c/m_b) \, |V_{cb}|^2 \; , \tag{28.13}$$

where τ_b is the b lifetime and $F(m_c/m_b)$ is a phase space factor that is approximately one-half. Most of the error on $|V_{cb}|$ derived from Eq. (28.13) is not from the experimental uncertainties, but in the theoretical uncertainties in choosing a value of m_b and in the use of the quark model to represent inclusively semileptonic decays which, at least for the B meson, are dominated by a few exclusive channels. Instead we use the nearly model-independent treatment in the heavy quark effective theory [32], where, in the case of $B \to D^*$ transitions, the decay rates at zero recoil are fixed by a normalization condition, with vanishing $1/m_q$ corrections [33]. From data of the ARGUS [34] and CLEO [35] experiments, we quote a value [36] derived from the decay of $\overline{B} \to D^* \ell \overline{\nu}_\ell$ of

$$|V_{cb}| = 0.040 \pm 0.005 \tag{28.14}$$

that is deduced using a B-lifetime of (1.49 ± 0.04) ps [37]. The central value and the error are now comparable to what is obtained from the inclusive semileptonic decays, but ultimately, with more data, exclusive semileptonic decays should provide the most accurate value of $|V_{cb}|$.

The results for three generations of quarks, from Eqs. 28.5, 28.7, 28.8, 28.11, 28.12, and 28.14 plus unitarity, are summarized in the matrix in Eq. (28.2). The ranges given there are different from those given in Eqs. (28.5)–(28.14) (because of the inclusion of unitarity), but are consistent with the one standard deviation errors on the input matrix elements.

The data do not preclude there being more than three generations. Moreover, the entries deduced from unitarity might be altered when the CKM matrix is expanded to accommodate more generations. Conversely, the known entries restrict the possible values of additional elements if the matrix is expanded to account for additional generations. For example, unitarity and the known elements of the first row require that any additional element in the first row have a magnitude $|V_{ub'}| < 0.07$. When there are more than three generations the allowed ranges (at 90% CL) of the matrix elements connecting the first three generations are

$$\begin{pmatrix} 0.9728 \text{ to } 0.9757 & 0.218 \text{ to } 0.224 & 0.002 \text{ to } 0.005 & \cdots \\ 0.180 \text{ to } 0.228 & 0.800 \text{ to } 0.975 & 0.032 \text{ to } 0.048 & \cdots \\ 0 \text{ to } 0.13 & 0 \text{ to } 0.56 & 0 \text{ to } 0.9995 & \cdots \\ \vdots & \vdots & \vdots & \end{pmatrix} , \tag{28.15}$$

where we have used unitarity (for the expanded matrix) and Eqs. 28.5, 28.7, 28.8, 28.11, 28.12, and 28.14.

Further information on the angles requires theoretical assumptions. For example, $B_d - \overline{B}_d$ mixing, if it originates from short distance contributions to ΔM_B dominated by box diagrams involving virtual t quarks, gives information on $V_{tb} V_{td}^*$ once hadronic matrix elements and the t quark mass are known. A similar comment holds for $V_{tb} V_{ts}^*$ and $B_s - \overline{B}_s$ mixing.

Direct and indirect information on the CKM matrix is neatly summarized in terms of the "unitarity triangle." The name arises since unitarity of the 3×3 CKM matrix applied to the first and third columns yields

$$V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0 \; . \tag{28.16}$$

The unitarity triangle is just a geometrical presentation of this equation in the complex plane [38]. We can always choose to orient the triange so that $V_{cd} V_{cb}^*$ is horizontal; in the parametrization we have chosen, V_{cb} is real, and V_{cd} is real to a very good approximation in any case. Setting cosines of small angles to unity, Eq. (28.16) becomes

$$V_{ub}^* + V_{td} = s_{12} V_{cb}^* \; , \tag{28.17}$$

which is shown as the unitarity triangle in Fig. 28.1(a). Rescaling the triangle by a factor $[1/|s_{12} V_{cb}|]$, the coordinates of the vertices become

$$A\big(\mathrm{Re}(V_{ub})/|s_{12} V_{cb}|, -\mathrm{Im}(V_{ub})/|s_{12} V_{cb}|\big) \; , \; B(1,0) \; , \; C(0,0) \; . \tag{28.18}$$

In the approximation of the Wolfenstein parametrization [5], with matrix elements expressed in powers of the Cabibbo angle, $\lambda \sim s_{12}$:

$$\begin{aligned} V_{us} &\sim \lambda \\ V_{ub} &\sim \lambda^3 A(\rho - i\eta) \\ V_{cb} &\sim \lambda^2 A \\ V_{td} &\sim \lambda^3 A(1 - \rho - i\eta) \; , \end{aligned} \tag{28.19}$$

the coordinates of the vertex A of the unitarity triangle are simply (ρ, η), as shown in Fig. 28.1(b).

CP-violating processes will involve the phase in the CKM matrix, assuming that the observed CP violation is solely related to a nonzero value of this phase. This allows additional constraints to be imposed. More specifically, a necessary and sufficient condition for CP violation with three generations can be formulated in a parametrization-independent manner in terms of the non-vanishing of the determinant of the commutator of the mass matrices for the charge $2e/3$ and charge $-e/3$ quarks [39]. CP violating amplitudes or differences of rates all are proportional to the CKM factor in this quantity. This is the product of factors $s_{12} s_{13} s_{23} c_{12} c_{13}^2 c_{23} s_{\delta_{13}}$ in the parametrization adopted above, and is $s_1^2 s_2 s_3 c_1 c_2 c_3 s_\delta$ in that of Ref. 1. With the approximation of setting cosines to unity, this is just twice the area of the unitarity triangle. While hadronic matrix elements whose values are imprecisely known generally now enter, the constraints from CP violation in the neutral kaon system are tight enough to very much restrict the range of angles and the phase of

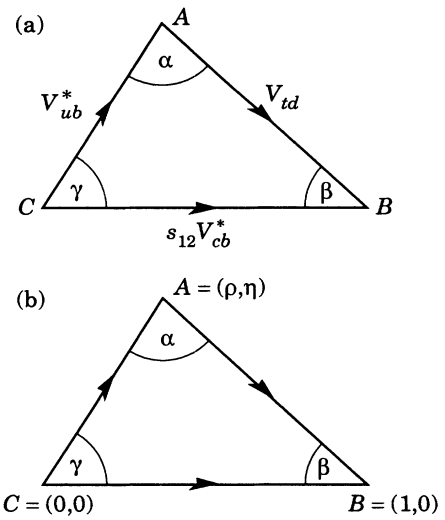

Figure 28.1: (a) Representation in the complex plane of the triangle formed by the CKM matrix elements V_{ub}^*, V_{td}, and $s_{12}V_{cb}$. (b) Rescaled triangle with vertices $A(\rho,\eta)$, $B(1,0)$, and $C(0,0)$.

the CKM matrix. For CP-violating asymmetries of neutral B mesons decaying to CP eigenstates, there is a direct relationship between the magnitude of the asymmetry in a given decay and $\sin 2\phi$, where $\phi = \alpha, \beta, \gamma$ is an appropriate angle of the unitarity triangle [38].

The combination of all the direct and indirect information can be used to find the overall constraints on the CKM matrix and thence the implications for future measurements of CP violation in the B system [40].

29. CP VIOLATION

This section prepared April 1994 by L. Wolfenstein.

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. Then CP violation was observed in K^0 decays at a level given by the parameter $\epsilon = 2.3 \times 10^{-3}$. Larger CP-violation effects are anticipated in B^0 decays.

The eigenstates of the K^0–$\overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle \ , \qquad |K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle \ . \tag{29.1}$$

If CP invariance held, we would have $q = p$ so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in K^0–$\overline{K}^0$ mixing gives

$$\frac{p}{q} = \frac{(1+\widetilde{\epsilon})}{(1-\widetilde{\epsilon})} \ . \tag{29.2}$$

CP violation can also occur in the decay amplitudes

$$A\big(K^0 \to \pi\pi(I)\big) = A_I e^{i\delta_I} \ , \qquad A\big(\overline{K}^0 \to \pi\pi(I)\big) = A_I^* e^{i\delta_I} \ , \tag{29.3}$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The ratios of CP-violating to CP-conserving amplitudes $\eta_{+-} = A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-)$ and $\eta_{00} = A(K_L^0 \to \pi^0\pi^0)/A(K_S^0 \to \pi^0\pi^0)$ can be written as

$$\eta_{+-} = \epsilon + \epsilon' \ , \qquad \eta_{00} = \epsilon - 2\epsilon' \ , \tag{29.4a}$$

$$\epsilon = \widetilde{\epsilon} + i\ (\mathrm{Im}\ A_0/\mathrm{Re}\ A_0) \ , \tag{29.4b}$$

$$|\sqrt{2}\epsilon'| = (\mathrm{Re}\ A_2/\mathrm{Re}\ A_0)\ \big(\mathrm{Im}\ A_2/\mathrm{Re}\ A_2 - \mathrm{Im}\ A_0/\mathrm{Re}\ A_0\big) \ . \tag{29.4c}$$

If CP violation is confined to the mass matrix, as in a superweak theory, ϵ' is zero and $\eta_{+-} = \eta_{00} = \epsilon = \widetilde{\epsilon}$. The measurement of ϵ'/ϵ has as its goal finding an effect that requires CP violation in the decay amplitude; this corresponds to a relative phase between A_2 and A_0 as seen in Eq. (29.4c).

In the Standard Model CP violation arises as a result of a single phase entering the CKM matrix (q.v.). As a result in what is now the standard phase convention, two elements have large phases, $V_{ub} \sim e^{-i\gamma}$, $V_{td} \sim e^{-i\beta}$. Because these elements have small magnitudes and involve the third generation, CP violation in the K^0 system is small. A definite nonzero value for ϵ'/ϵ is expected but hadronic uncertainties allow theoretical values between 10^{-4} and 3×10^{-3}. On the other hand, large effects are expected in the B^0 system, which is a major motivation for B factories.

The most clearcut experiments would be those that measure asymmetries between B^0 and $\overline{B}^0$ decays. The time-dependent rate to a CP eigenstate a is given by

$$\Gamma_a \sim e^{-\Gamma t}\Big(\big[1 + |r_a|^2\big] \pm \big[1 - |r_a|^2\big]\ \cos(\Delta M t) \mp 2\eta_a \mathrm{Im}\ r_a\ \sin(\Delta M t)\Big) \ , \tag{29.5}$$

where the top sign is for B^0 and the bottom for $\overline{B}^0$, η_a is the CP eigenvalue and

$$r_a = (q_B/p_B)\ \overline{A}_a/A_a \ . \tag{29.6}$$

The quantity (q_B/p_B) comes from the analogue for B^0 of Eq. (29.1); however, for B^0 the eigenstates have a negligible lifetime difference and are distinguished only by the mass difference ΔM; also as a result $|q_B/p_B| \approx 1$ so that $\widetilde{\epsilon}_B$ is purely imaginary. A_a ($\overline{A}_a$) are the decay amplitudes to a for B^0 ($\overline{B}^0$). If only one quark weak transition contributes to the decay $|\overline{A}_a/A_a| = 1$ so that $|r_a| = 1$ and the $\cos(\Delta M t)$ term vanishes. The basic goal of the B factories is to observe the asymmetric $\sin(\Delta M t)$ term. For B^0 ($\overline{B}^0$) $\to \psi K_s$ from the transition $b \to c\bar{c}s$, one finds in the Standard Model the asymmetry parameter

$$-2\mathrm{Im}\ r_a = \sin 2\beta \ . \tag{29.7}$$

The asymmetry is given directly in terms of a CKM phase with no hadronic uncertainty and is expected to be between 0.2 and 0.8. For B^0 ($\overline{B}^0$) $\to \pi^+\pi^-$ from the transition $b \to u\bar{u}d$

$$-2\mathrm{Im}\ r_a = \sin 2(\beta + \gamma) \ . \tag{29.8}$$

(This result has some hadronic uncertainty due to penguin contributions, but these should be able to be estimated from other observations.) While either of these asymmetries could be ascribed to $B^0 - \overline{B}^0$ mixing (q_B/p_B or $\widetilde{\epsilon}_B$), the difference between the two asymmetries is evidence for direct CP violation. From Eq. (29.6) (with $\overline{A}_a/A_a = 1$) it is seen this corresponds to a phase difference between $A_{\psi K_S}$ and $A_{\pi^+\pi^-}$. Thus this is analogous to ϵ'. In the standard phase convention 2β in Eq. (29.7) and (29.8) arises from $B^0 - \overline{B}^0$ mixing whereas the 2γ comes from V_{bu} in the transition $b \to u\bar{u}d$.

CP violation in the decay amplitude is also revealed by the $\cos(\Delta M t)$ in Eq. (29.5) or by a difference in rates of B^+ and B^- to charge-conjugate states. These effects, however, require two contributing amplitudes to the decay (such as a tree amplitude plus a penguin) and also require final-state interaction phases. Predicted effects are very uncertain and are generally small.

For further details, see the notes on CP violation in the K_L^0, K_S^0, and B^0 Full Data Listings of this *Review*.

30. QUARK MODEL

30.1. Quantum numbers of the quarks

Each quark has spin 1/2 and baryon number 1/3. Table 30.1 gives the additive quantum numbers (other than baryon number) of the three generations of quarks. Our convention is that the *flavor* of a quark (I_z, S, C, B, or T) has the same sign as its *charge*. With this convention, any flavor carried by a *charged* meson has the same sign as its charge; *e.g.*, the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm *and* strangeness of the D_s^- are each −1.

By convention, each quark is assigned positive parity. Then each antiquark has negative parity.

Table 30.1: Additive quantum numbers of the quarks.

Property \ Quark	d	u	s	c	b	t
Q – electric charge	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$
I_z – isospin z-component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	−1	0	0	0
C – charm	0	0	0	+1	0	0
B – bottomness	0	0	0	0	−1	0
T – topness	0	0	0	0	0	+1

30.2. Mesons: $q\bar{q}$ states

Nearly all known mesons are bound states of a quark q and an antiquark $\bar{q}'$ (the flavors of q and q' may be different). If the orbital angular momentum of the $q\bar{q}'$ state is L, then the parity P is $(-1)^{L+1}$. A state $q\bar{q}$ of a quark and its own antiquark is also an eigenstate of charge conjugation, with $C = (-1)^{L+S}$, where the spin S is 0 or 1. The $L = 0$ states are the pseudoscalars, $J^P = 0^-$, and the vectors, $J^P = 1^-$. Assignments for many of the known mesons are given in Table 30.2. States in the "normal" spin-parity series, $P = (-1)^J$, must, according to the above, have $S = 1$ and hence $CP = +1$. Thus mesons with normal spin-parity and $CP = -1$ are forbidden in the $q\bar{q}'$ model. The $J^{PC} = 0^{--}$ state is forbidden as well. Mesons with such J^{PC} may exist, but would lie outside the $q\bar{q}'$ model.

The nine possible $q\bar{q}'$ combinations containing u, d, and s quarks group themselves into an octet and a singlet:

$$\mathbf{3} \otimes \bar{\mathbf{3}} = \mathbf{8} \oplus \mathbf{1} \tag{30.1}$$

States with the same IJ^P and additive quantum numbers can mix. (If they are eigenstates of charge conjugation, they must also have the same value of C.) Thus the $I = 0$ member of the ground-state pseudoscalar octet mixes with the corresponding pseudoscalar singlet to produce the η and η'. These appear as members of a nonet, which is shown as the middle plane in Fig. 30.1(a). Similarly, the ground-state vector nonet appears as the middle plane in Fig. 30.1(b).

A fourth quark such as charm can be included in this scheme by extending the symmetry to SU(4), as shown in Fig. 30.1. Bottom extends the symmetry to SU(5); to draw the multiplets would require four dimensions.

For the pseudoscalar mesons, the Gell-Mann-Okubo formula is

$$m_\eta^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)\ , \tag{30.2}$$

assuming no octet-singlet mixing. However, the octet η_8 and singlet η_1 mix because of SU(3) breaking. In general, the mixing angle is mass dependent and becomes complex for resonances of finite width.

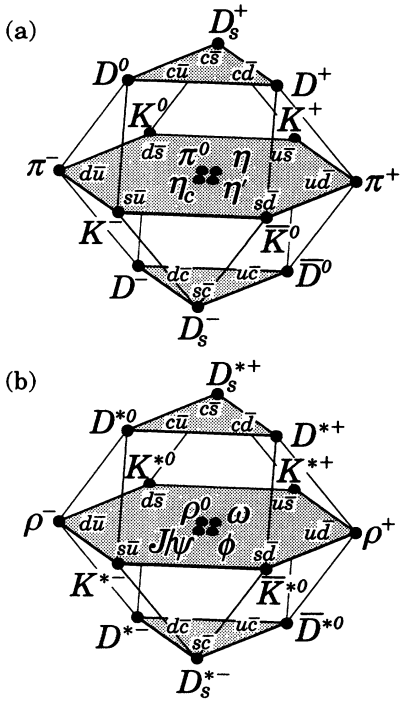

Figure 30.1: SU(4) 16-plets for the (a) pseudoscalar and (b) vector mesons made of u, d, s, and c quarks. The nonets of light mesons occupy the central planes, to which the $c\bar{c}$ states have been added. The neutral mesons at the centers of these planes are mixtures of $u\bar{u}$, $d\bar{d}$, $s\bar{s}$, and $c\bar{c}$ states.

Neglecting this, the physical states η and η' are given in terms of a mixing angle θ_P by

$$\eta = \eta_8 \cos\theta_P - \eta_1 \sin\theta_P \tag{30.3a}$$

$$\eta' = \eta_8 \sin\theta_P + \eta_1 \cos\theta_P\ . \tag{30.3b}$$

These combinations diagonalize the mass-squared matrix

$$M^2 = \begin{pmatrix} M_{11}^2 & M_{18}^2 \\ M_{18}^2 & M_{88}^2 \end{pmatrix}\ , \tag{30.4}$$

where $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)$. It follows that

$$\tan^2\theta_P = \frac{M_{88}^2 - m_\eta^2}{m_{\eta'}^2 - M_{88}^2}\ . \tag{30.5}$$

The sign of θ_P is meaningful in the quark model. If

$$\eta_1 = (u\bar{u} + d\bar{d} + s\bar{s})/\sqrt{3} \tag{30.6a}$$

$$\eta_8 = (u\bar{u} + d\bar{d} - 2s\bar{s})/\sqrt{6}\ , \tag{30.6b}$$

then the matrix element M_{18}^2, which is due mostly to the strange quark mass, is negative. From the relation

$$\tan\theta_P = \frac{M_{88}^2 - m_\eta^2}{M_{18}^2}\ , \tag{30.7}$$

we find that $\theta_P < 0$. However, caution is suggested in the use of the η-η' mixing-angle formulas, as they are extremely sensitive to SU(3)

Table 30.2: Suggested $q\bar{q}$ quark-model assignments for most of the known mesons. Some assignments, especially for the 0^{++} multiplet and for some of the higher multiplets, are controversial. Mesons in bold face are included in the Meson Summary Table. Of the light mesons in the Summary Table, the $f_1(1420)$, $f_0(1590)$, $f_J(1710)$, $f_2(2300)$, $f_2(2340)$, and the two peaks in the $\eta(1440)$ entry are not in this table. Within the $q\bar{q}$ model, it is especially hard to find a place for the first three of these f mesons and for one of the $\eta(1440)$ peaks. See the "Note on Non-$q\bar{q}$ Mesons" at the end of the Meson Listings.

† The K_{1A} and K_{1B} are nearly equal (45°) mixes of the $K_1(1270)$ and $K_1(1400)$.

‡The $K^*(1410)$ could be replaced by the $K^*(1680)$ as the $2\,^3S_1$ state.

breaking. If we allow $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)\,(1+\Delta)$, the mixing angle is determined by

$$\tan^2\theta_P = 0.0319(1+17\Delta) \tag{30.8}$$

$$\theta_P = -10.1^\circ(1+8.5\Delta) \tag{30.9}$$

to first order in Δ. A small breaking of the Gell-Mann-Okubo relation can produce a major modification of θ_P.

For the vector mesons, $\pi \to \rho$, $K \to K^*$, $\eta \to \phi$, and $\eta' \to \omega$, so that

$$\phi = \omega_8 \cos\theta_V - \omega_1 \sin\theta_V \tag{30.10}$$

$$\omega = \omega_8 \sin\theta_V + \omega_1 \cos\theta_V\ . \tag{30.11}$$

For "ideal" mixing, $\phi = s\bar{s}$, so $\tan\theta_V = 1/\sqrt{2}$ and $\theta_V = 35.3^\circ$. Experimentally, θ_V is near 35°, the sign being determined by a formula like that for $\tan\theta_P$. Following this procedure we find the mixing angles given in Table 30.3.

Table 30.3: Singlet-octet mixing angles for several nonets, neglecting possible mass dependence and imaginary parts. The sign conventions are given in the text. The values of $\theta_{\rm quad}$ are obtained from the equations in the text, while those for $\theta_{\rm lin}$ are obtained by replacing m^2 by m throughout. Of the two isosinglets in a nonet, the mostly octet one is listed first.

J^{PC}	Nonet members	$\theta_{\rm quad}$	$\theta_{\rm lin}$
0^{-+}	π, K, η, η'	-10°	-23°
1^{--}	ρ, $K^*(892)$, ϕ, ω	39°	36°
2^{++}	$a_2(1320)$, $K_2^*(1430)$, $f_2'(1525)$, $f_2(1270)$	28°	26°
3^{--}	$\rho_3(1690)$, $K_3^*(1780)$, $\phi_3(1850)$, $\omega_3(1670)$	29°	28°

In the quark model, the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the i-th quark. This provides an alternative characterization of mixing. For example, defining

$$\text{Amp}\,[P \to \gamma(k_1)\,\gamma(k_2)] = M\epsilon^{\mu\nu\alpha\beta}\,\epsilon^*_{1\mu}\,k_{1\nu}\,\epsilon^*_{2\alpha}\,k_{2\beta}\,, \tag{30.12}$$

where $\epsilon_{i\lambda}$ is the λ component of the polarization vector of the i^{th} photon, one finds

$$\frac{M(\eta \to \gamma\gamma)}{M(\pi^0 \to \gamma\gamma)} = \frac{1}{\sqrt{3}}(\cos\theta_P - 2\sqrt{2}\sin\theta_P)$$
$$= \frac{1.73 \pm 0.18}{\sqrt{3}} \tag{30.13a}$$

$$\frac{M(\eta' \to \gamma\gamma)}{M(\pi^0 \to \gamma\gamma)} = 2\sqrt{2/3}\left(\cos\theta_P + \frac{\sin\theta_P}{2\sqrt{2}}\right)$$
$$= 2\sqrt{2/3}\,(0.78 \pm 0.04)\,, \tag{30.13b}$$

where the numbers with errors are experimental. These data favor $\theta_P \approx -20°$, which is compatible with the quadratic mass mixing formula with about 12% SU(3) breaking in M_{88}^2.

30.3. Baryons: *qqq* states

All the established baryons are apparently 3-quark (qqq) states, and each such state is an SU(3) color singlet, a completely antisymmetric state of the three possible colors. Since the quarks are fermions, the state function for any baryon must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus the state function may be written as

$$|\,qqq\,\rangle_A = |\,\text{color}\,\rangle_A \times |\,\text{space, spin, flavor}\,\rangle_S\,, \tag{30.14}$$

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two of the equal-mass quarks. Note the contrast with the state function for the three nucleons in ^{3}H or ^{3}He:

$$|\,NNN\,\rangle_A = |\,\text{space, spin, isospin}\,\rangle_A\,. \tag{30.15}$$

This difference has major implications for internal structure, magnetic moments, *etc.* (For a nice discussion, see Ref. 1.)

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor SU(3), which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \tag{30.16}$$

(see Sec. 22, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The **1** is a uds state (Λ_1) and the octet contains a similar state (Λ_8). If these have the same spin and parity they can mix. An example is the mainly octet D_{03} $\Lambda(1690)$ and mainly singlet D_{03} $\Lambda(1520)$. In the ground state multiplet, the SU(3) flavor singlet Λ is forbidden by Fermi statistics. The mixing formalism is the same as for η-η' or ϕ-ω (see above), except that for baryons the mass M instead of M^2 is used. Section 21, on "SU(3) Isoscalar Factors and Representation Matrices", shows how relative decay rates in, say, $\mathbf{10} \to \mathbf{8} \otimes \mathbf{8}$ decays may be calculated. A summary of results of fits to the observed baryon masses and decay rates for the best-known SU(3) multiplets is given in Appendix II of our 1982 edition [2].

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). Figures 30.2(a) and 30.2(b) show the (badly broken) SU(4) baryon multiplets that have as their "ground floors" the SU(3) octet that contains the nucleons and the SU(3) decuplet that contains the $\Delta(1232)$. All the particles in a given SU(4) multiplet have the same spin and parity. The only charmed baryons that have been discovered each contain one charmed quark. These belong to the first floor of the multiplet shown in Fig. 30.2(a); for details, see

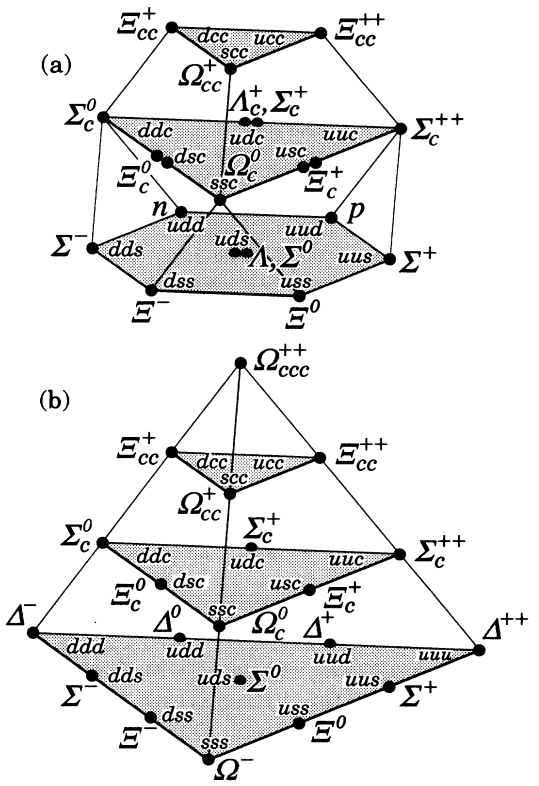

Figure 30.2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

the "Note on Charmed Baryons" in the Baryon Full Listings. The addition of a b quark extends the flavor symmetry to SU(5); it would require four dimensions to draw the multiplets.

For the "ordinary" baryons, flavor and spin may be combined in an approximate flavor-spin SU(6) in which the six basic states are $d\uparrow$, $d\downarrow$, $\cdots$, $s\downarrow$ ($\uparrow$, $\downarrow$ = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A\,. \tag{30.17}$$

These SU(6) multiplets decompose into flavor SU(3) multiplets as follows:

$$\mathbf{56} = {}^4\mathbf{10} \oplus {}^2\mathbf{8} \tag{30.18a}$$

$$\mathbf{70} = {}^2\mathbf{10} \oplus {}^4\mathbf{8} \oplus {}^2\mathbf{8} \oplus {}^2\mathbf{1} \tag{30.18b}$$

$$\mathbf{20} = {}^2\mathbf{8} \oplus {}^4\mathbf{1}\,, \tag{30.18c}$$

where the superscript $(2S+1)$ gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P = 1/2^+$ octet containing the nucleon and the $J^P = 3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The **70** and **20** require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in SU(6)⊗O(3) supermultiplets. Physical baryons with the same quantum numbers do not belong to a single supermultiplet, since SU(6) is broken by spin-dependent interactions, differences in quark masses, *etc.* Nevertheless, the SU(6)⊗O(3) basis provides a suitable framework for describing baryon state functions.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of

supermultiplets, specified by (D, L_N^P), where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to $N = 12$ are given in Ref. 3. The $N = 0$ band, which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The $N = 1$ band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The $N = 2$ band contains five supermultiplets: $(56,0_2^+)$, $(70,0_2^+)$, $(56,2_2^+)$, $(70,2_2^+)$, and $(20,1_2^+)$. Baryons belonging to the $(20,1_2^+)$ supermultiplet are not ever likely to be observed, since a coupling from the ground-state baryons requires a two-quark excitation. Selection rules are similarly responsible for the fact that many other baryon resonances have not been observed [4].

In Table 30.4, quark-model assignments are given for many of the established baryons whose SU(6)⊗O(3) compositions are relatively unmixed. We note that the unestablished resonances $\Sigma(1480)$, $\Sigma(1560)$, $\Sigma(1580)$, $\Sigma(1770)$, and $\Xi(1620)$ in our Baryon Full Listings are too low in mass to be accommodated in most quark models [4,5].

Table 30.4: Quark-model assignments for many of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for some states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses.

The quark model for baryons is extensively reviewed in Ref. 6 and 7.

30.4. Dynamics

Many specific quark models exist, but most contain the same basic set of dynamical ingredients. These include:

i) A confining interaction, which is generally spin-independent.

ii) A spin-dependent interaction, modeled after the effects of gluon exchange in QCD. For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\vec{\sigma}\lambda_a)_i (\vec{\sigma}\lambda_a)_j \ , \tag{30.19}$$

where M is a constant with units of energy, λ_a $(a = 1, \cdots, 8,)$ is the set of SU(3) unitary spin matrices, defined in Sec. 21, on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small.

iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets.

iv) In the case of isoscalar mesons, an interaction for mixing $q\bar{q}$ configurations of different flavors (*e.g.*, $u\bar{u} \leftrightarrow d\bar{d} \leftrightarrow s\bar{s}$), in a manner which is generally chosen to be flavor independent.

These four ingredients provide the basic mechanisms that determine the hadron spectrum.

31.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light (u, d, and s) quarks. Otherwise, the only important change to known hadrons was that the $F^\pm$ became the $D_s^\pm$. None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ, Υ, and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternate, and as the primary name when the spectroscopic identity is not known.

31.2. "Neutral-flavor" mesons ($S=C=B=T=0$)

Table 31.1 shows the naming scheme for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all mesons, whether ordinary or exotic. (This isn't quite true. We haven't proposed names for mesons whose charge Q, strangeness S, or other *additive* quantum numbers can't be matched by a $q\bar{q}$ state. For example, we have no name for a meson with $Q=2$, or for one with $Q=-1$ and $S=+1$.)

First, we assign names to those states with quantum numbers compatible with being $q\bar{q}$ states. The rows of the Table give the possible $q\bar{q}$ content. The columns give the possible parity/charge-conjugation states, $PC = -+$, $+-$, $--$, and $++$; these combinations correspond one-to-one with the angular-momentum state $^{2S+1}L_J$ of the $q\bar{q}$ system being $^1(L\text{ even})_J$, $^1(L\text{ odd})_J$, $^3(L\text{ even})_J$, or $^3(L\text{ odd})_J$. Here S, L, and J are the spin, orbital, and total angular momenta of the $q\bar{q}$ system. The relations between the quantum numbers are $P=(-1)^{L+1}$, $C=(-1)^{L+S}$, and G parity $=(-1)^{L+S+I}$, where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the particle symbols. The meson spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for any meson that decays strongly. However, for the lightest meson resonances, we sometimes omit the mass, as in ρ for $\rho(770)$, ϕ for $\phi(1020)$, *etc.*

Measurements of the mass, quark content (where relevant), and quantum numbers I, J, P, and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\bar{u}$ and $d\bar{d}$ or is mainly $s\bar{s}$. A prime (or symbol ϕ) may be used to distinguish two such mixing states.

Names are assigned for $t\bar{t}$ mesons, even though the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\bar{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\bar{q}$ mesons. Such states will probably be difficult to distinguish from $q\bar{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\bar{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\bar{q}$ system cannot have, namely $J^{PC} = 0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, \cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. Then a caret or "hat" is added; for example, an isospin-1 0^{--} meson would be a $\widehat{\pi}$, an isospin-0 1^{-+} meson would be an $\widehat{\omega}$.

The results of all this are as follows. Established mesons whose names changed slightly in 1986 are:

Old name	New name	Old name	New name
$H(1190)$	$h_1(1170)$	$A_2(1320)$	$a_2(1320)$
$B(1235)$	$b_1(1235)$	$f'(1525)$	$f_2'(1525)$
$A_1(1270)$	$a_1(1260)$	$\omega(1670)$	$\omega_3(1670)$
$f(1270)$	$f_2(1270)$		

Established mesons whose names changed completely are:

Old name	New name	Old name	New name
$S(975)$	$f_0(980)$	$g(1690)$	$\rho_3(1690)$
$\delta(980)$	$a_0(980)$	$\theta(1690)$	$f_J(1710)$
$D(1285)$	$f_1(1285)$	$X(1850)$	$\phi_3(1850)$
$\epsilon(1200)$	$f_0(1300)$	$g_T(2010)$	$f_2(2010)$
$E(1420)$	$f_1(1420)$	$h(2030)$	$f_4(2050)$
$\iota(1440)$	$\eta(1440)$	$g_T'(2300)$	$f_2(2300)$
$D(1530)$	$f_1(1510)$	$g_T''(2340)$	$f_2(2340)$
$A_3(1680)$	$\pi_2(1670)$		

The old $S(975)$, $D(1285)$, $\epsilon(1200)$, $E(1420)$, $D(1530)$, $\theta(1690)$, $g_T(2010)$, $h(2030)$, $g_T'(2300)$, and $g_T''(2340)$ all became f mesons; the new scheme revealed that they are all $PC = ++$, $^3(L\text{ odd})_J$ states.

31.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

1. The main symbol is an upper-case italic letter indicating the heavier quark as follows:

   $s \to \overline{K}$ $\quad c \to D$ $\quad b \to \overline{B}$ $\quad t \to T$.

   We use the convention that *the flavor and the charge of a quark have the same sign.* Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: *Any flavor carried by a charged meson has the same sign as its charge.* Thus the K^+, D^+, and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3. The D_s^+ has positive charm *and* strangeness. Furthermore, the $\Delta(\text{flavor}) = \Delta Q$ rule, best known for the kaons, applies to every flavor.
2. If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s^+ is an example.
3. If the spin-parity is in the "normal" series, $J^P = 0^+, 1^-, 2^+, \cdots$, a superscript "*" is added.
4. The spin is added as a subscript unless the meson is a pseudoscalar or a vector particle.

Thus the pseudoscalar and vector K, K^*, D, D^*, and B mesons did not change names. Established mesons whose names did change were:

Old name	New name	Old name	New name
$Q_1(1280)$	$K_1(1270)$	$L(1770)$	$K_2(1770)$
$Q_2(1400)$	$K_1(1400)$	$K^*(1780)$	$K_3^*(1780)$
$\kappa(1350)$	$K_0^*(1430)$	$K^*(2060)$	$K_4^*(2045)$
$K^*(1430)$	$K_2^*(1430)$	F	D_s

Most notably, the F (the $c\bar{s}$ state) became the D_s.

31.4. Baryons

The symbols N, Δ, Λ, Σ, Ξ, and Ω used for 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols now used for the baryons containing one or more heavy quarks (c, b, and t quarks). The rules are:

1. Baryons with *three* u and/or d quarks are N's (isospin 1/2) or Δ's (isospin 3/2).
2. Baryons with *two* u and/or d quarks are Λ's (isospin 0) or Σ's (isospin 1). If the third quark is a c, b, or t quark, its identity is given by a subscript.
3. Baryons with *one* u or d quark are Ξ's (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus Ξ_c, Ξ_{cc}, Ξ_b, *etc.*
4. Baryons with *no* u or d quarks are Ω's (isospin 0), and subscripts indicate any heavy-quark content.

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0, *etc.*

32. MONTE CARLO PARTICLE NUMBERING SCHEME

Written April 1988 by G.R. Lynch and T.G. Trippe.

Most particle physics Monte Carlo and analysis systems use a numbering scheme to represent particles. The lack of standardization of such schemes inhibits interfacing different programs. The following table proposes a standard numbering scheme. Some of the properties of this scheme are:

1. Quarks and leptons are ordered by family, and within the family, by isospin. This puts the u and d in the opposite order than is often used in other numbering schemes. In our scheme we call the highest numbered quark the heaviest quark.
2. For multiple quark systems (mesons, baryons, and diquarks), the rightmost digit is generally $L = 2J + 1$. (The K_S^0 and K_L^0 are exceptions.) Particles with $J > 4$ have not been assigned numbers.
3. Mesons are represented by the form NML and baryons by $NMKL$, where N, M, and K are quark numbers.
4. For these systems the heaviest quark is usually on the left and the quarks are in decreasing mass order from left to right. One exception to this convention is the K_L^0-K_S^0 pair. A second exception is for the Λ's for which we invert the up and down quarks to distinguish the Λ from the Σ^0.
5. The other exception to this mass order rule is for some N's and Δ's. For N's, the u and d quark are reversed for spins 3/2 and 7/2. For Δ's, they are reversed for spins 1/2 and 5/2. The quarks are in the normal decreasing order when $I + J$ is odd.
6. Mesons, and only mesons, have the third digit nonzero and the fourth digit zero. (We designate the rightmost digit as the first digit.)
7. Only baryons and diquarks have the fourth digit nonzero.
8. Only quarks and diquarks have the second digit equal to zero.
9. Particles have positive numbers; each antiparticle has the negative of its counterpart.
10. The particle-antiparticle convention is the one used by the Particle Data Group, so that the K^+ and B^+ are particles.
11. The above rules imply that for mesons (as opposed to antimesons), when the number of the leftmost (heaviest) quark is even, it is a quark, and when the number of the leftmost quark is odd, it is an antiquark.
12. The gluon has two numbers. Its official number is 21 to place it with the other gauge bosons. Its number is also 9 so that a glueball is specified as 99.
13. The fifth digit is used to differentiate different particles with the same quark content and spin.
14. Although isospin is not manifest in this scheme, the isospin of any hadron can be determined from the number. Mesons with $11L$ are isospin 1 and those with $22L$ are isospin 0. For nonstrange baryons, if the quarks are in the normal decreasing order, then $I + J$ is odd, otherwise $I + J$ is even. If a strange baryon does not have the normal decreasing quark order, it has $I = 0$.

More details about the motivation behind, and properties of, this scheme can be found in Ref. 1. Although this scheme has the advantage that a particle's number has considerable physics content, it has the disadvantage that it is not compact. An algorithm that translates this scheme into a more compact scheme is needed for its implementation. Contact the Berkeley Particle Data Group for further information on such an algorithm.

A list of particle numbers follows.

33. PLOTS OF CROSS SECTIONS AND RELATED QUANTITIES

NOTE: THE FIGURES IN THIS SECTION ARE INTENDED TO SHOW THE REPRESENTATIVE DATA.
THEY ARE NOT MEANT TO BE COMPLETE COMPILATIONS OF ALL THE WORLD'S RELIABLE DATA

Structure Functions

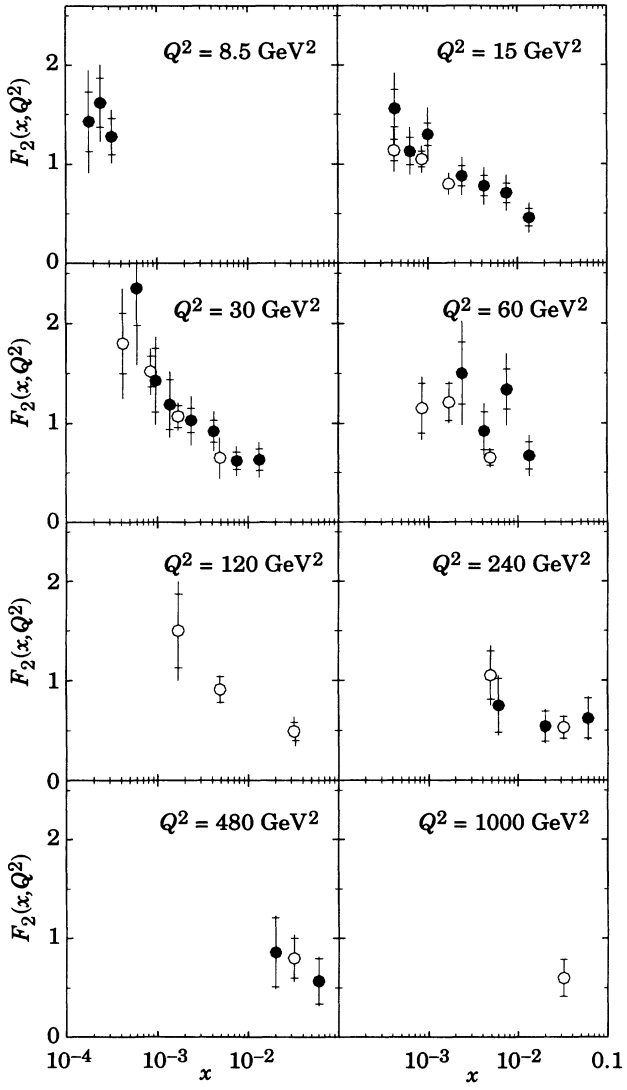

Figure 32.1: The proton structure function F_2^p measured in electromagnetic scattering of 26.7 GeV electrons on 820 GeV protons by the HERA experiments, versus x, for fixed bins of Q^2. The closed symbols show H1 and the open symbols ZEUS data obtained with luminosities of 22.5 nb^{-1} and 24.7 nb^{-1}, respectively. A QCD prescription for $R = \sigma_L/\sigma_T$ was used to extract the structure function from the measured cross sections. The inner error bars are statistical, the outer error bars are statistical and systematic errors combined in quadrature. An overall normalization error of $\approx 8\%$ is not shown in the figure. References: **H1**—I. Abt *et al.*, Nucl. Phys. **B407**, 515 (1993) and G. Bernardi, *Proceedings International Europhysics Conference on High Energy Physics*, (Marseille 1993), ed. by J. Carr and M. Perrottet; **ZEUS**—M. Derrick *et al.*, Phys. Lett. **B316**, 412 (1993). (Courtesy of M. Virchaux and R. Voss, 1994.)

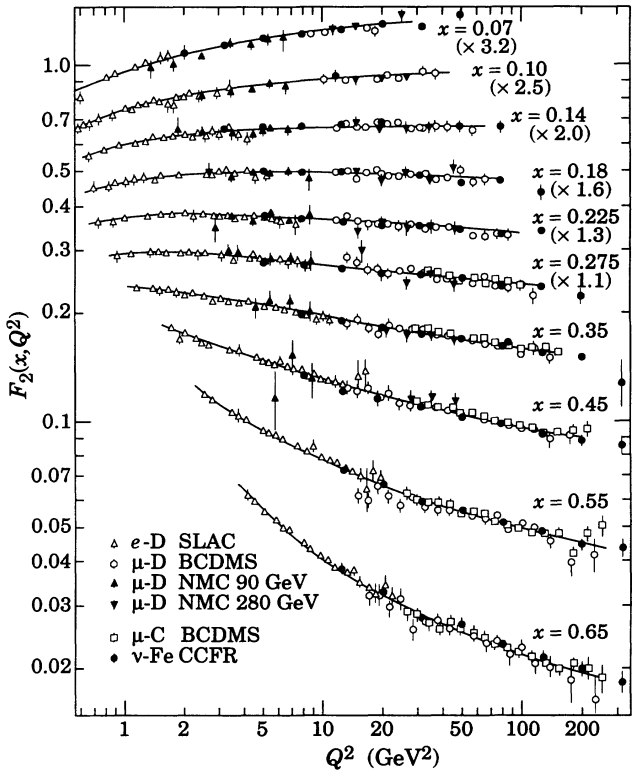

Figure 32.2: The nucleon structure function F_2 measured in deep inelastic scattering of electrons (SLAC), muons (BCDMS, NMC), and neutrinos (CCFR) on deuterium (BCDMS, NMC, SLAC), carbon (BCDMS C), and iron (CCFR Fe) targets. The data are shown versus Q^2, for fixed bins of x, and have been scaled by the factors shown in parentheses for convenience in plotting. The error bars show statistical and systematic errors combined in quadrature. The heavy target data were corrected for nuclear effects and the neutrino data for electromagnetic quark charges and the excess of the strange quark sea. The overall normalization of the BCDMS, CCFR, and NMC data has been adjusted by typically 1%. The solid line represents a perturbative QCD fit which includes a parameterization of higher twist effects (M. Virchaux and A. Milsztajn, Phys. Lett. **B274**, 221 (1992)). References: **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B237**, 592 (1990); **BCDMS C**—A.C. Benvenuti *et al.*, Phys. Lett. **B195**, 91 (1987); **CCFR**—S.R. Mishra *et al.*, NEVIS-1465 (1992); **NMC**— P. Amaudruz *et al.*, Phys. Lett. **B295**, 159 (1992); **SLAC**—L.W. Whitlow *et al.*, Phys. Lett. **B282**, 475 (1992). (Courtesy of M. Virchaux and R. Voss, 1994.)

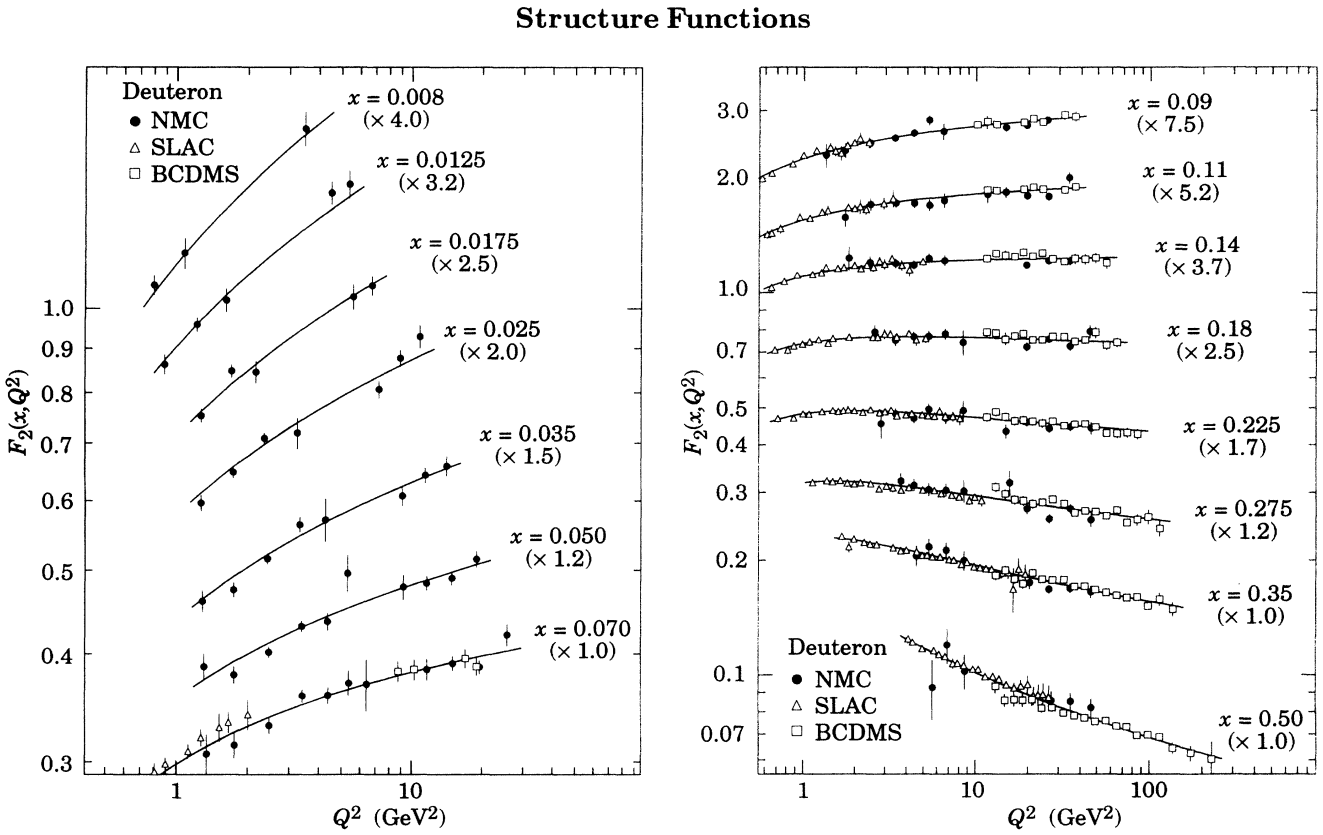

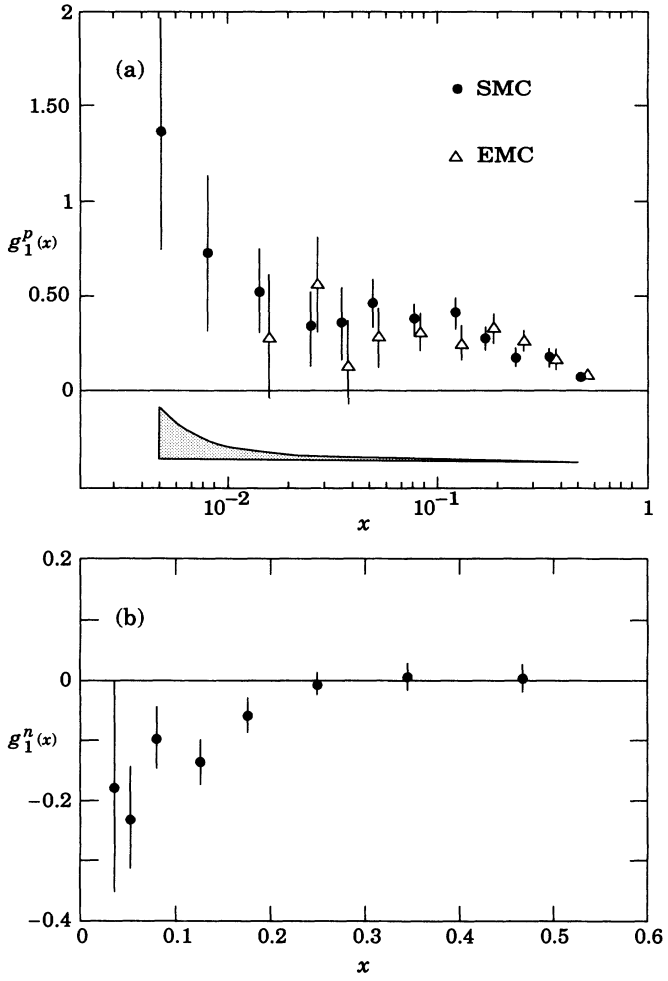

Figure 32.3: The deuteron structure function F_2^d measured in electromagnetic scattering of electrons (SLAC) and muons (BCDMS, NMC) on deuterium targets, versus Q^2, for fixed bins of x. The data have been scaled by the factors shown in parentheses for convenience in plotting. The error bars show statistical and systematic errors combined in quadrature. A phenomenological parameterization of $R = \sigma_L/\sigma_T$ (L.W. Whitlow *et al.*, Phys. Lett. **B250**, 193 (1990)) was used in the analysis of the SLAC and the NMC data and a QCD prescription for R in the analysis of the BCDMS data. Where necessary, the SLAC and BCDMS data were interpolated to the x bins of the NMC data; SLAC and BCDMS data at $x > 0.5$ are not shown in this figure. The solid lines represent a QCD inspired phenomenological fit. References: **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B237**, 592 (1990); **NMC**—P. Amaudruz *et al.*, Phys. Lett. **B295**, 159 (1992); **SLAC**—L.W. Whitlow *et al.*, Phys. Lett. **B282**, 475 (1992). Similar data are available for the proton structure function F_2^p (**NMC** and **SLAC**—same references; **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B223**, 485 (1989)). (Courtesy of M. Virchaux and R. Voss, 1994.)

Structure Functions

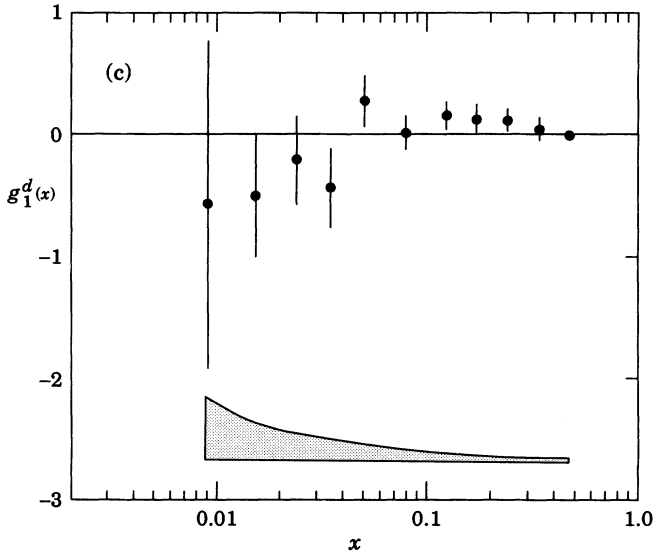

Figure 32.4: The spin-dependent structure function g_1 measured in deep inelastic scattering of polarised electrons (b) and muons (a,c) on polarised protons (a, EMC and SMC), neutrons (b, E142), and deuterons (c, SMC). For the muon data, only statistical errors are are shown with the data points and the size of the systematic errors is indicated by the shaded bands. For the electron data, statistical and systematic errors are combined in quadrature. The data are shown versus x; for each of the four experiments, the Q^2 of the data increases with increasing x. The average Q^2 is also different for each of the four experiments; all data in this plot are at 1 GeV^2 < Q^2 < 60 GeV^2. References: **E142**—P.L. Anthony *et al.*, Phys. Rev. Lett. **71**, 959 (1993); **EMC**—J. Ashman *et al.*, Nucl. Phys. **B328**, 1 (1989); **SMC**—B. Adeva *et al.*, Phys. Lett. **B302**, 533 (1993); D. Adams *et al.*, CERN-PPE/94-57. (Courtesy of M. Virchaux and R. Voss, 1994.)

Jet Production in pp and $\overline{p}p$ Interactions

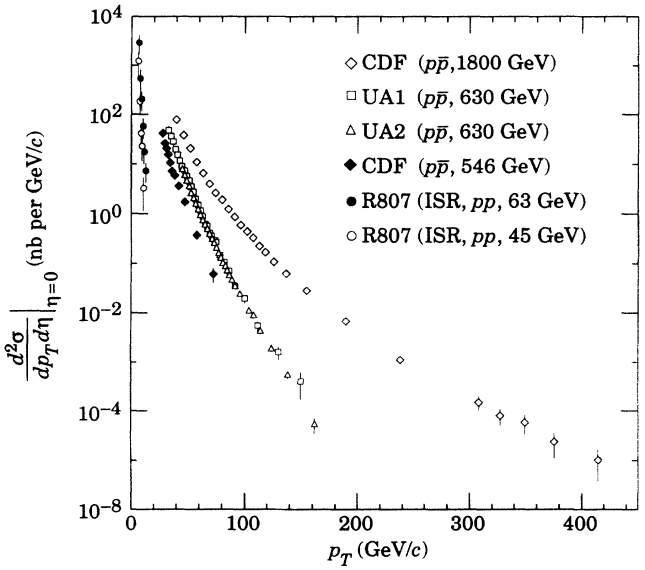

Figure 32.5: Differential cross sections for observation of a single jet of pseudorapidity $\eta = 0$ as a function of the jet transverse momentum. **CDF**—F. Abe *et al.*, Phys. Rev. Lett. **70**, 1376 (1993); **UA1**—G. Arnison *et al.*, Phys. Lett. **B172**, 461 (1986); **UA2**—J. Alitti *et al.*, Phys. Lett. **B257**, 232 (1991); **R807**—T. Akesson *et al.*, Phys. Lett. **B123**, 133 (1983). (Courtesy of S. Geer, FNAL, 1994.)

Direct γ Production in $\overline{p}p$ Interactions

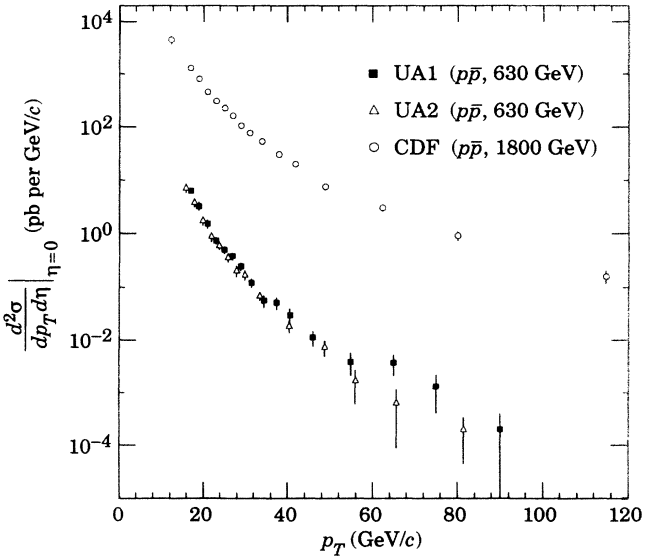

Figure 32.6: Differential cross sections for observation of a single photon of pseudorapidity $\eta = 0$ as a function of the photon transverse momentum **UA1**—C. Albajar *et al.*, Phys. Lett. **B209**, 385 (1988); **UA2**—J. Alitti *et al.*, Phys. Lett. **B288**, 386 (1992); **CDF**—Fermilab-CONF-94/148-E. (Courtesy of S. Geer, FNAL, 1994.)

Pseudorapidity Distributions in $\overline{p}p$ Interactions

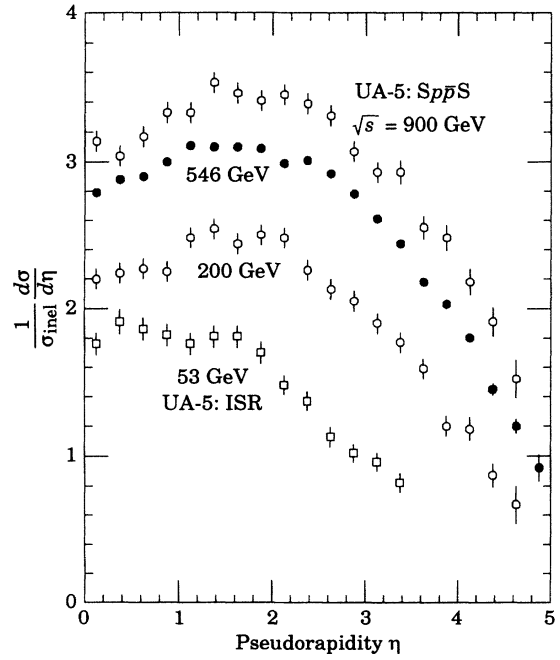

Figure 32.7: Charge particle pseudorapidity distributions in $p\bar{p}$ collisions for 53 GeV $\leq \sqrt{s} \leq$ 900 GeV. The number per pseudorapidity interval is about 10% higher if the rate is normalized excluding singly diffractive events rather than to the total inelastic rate. S$p\bar{p}$S data are from G.J. Alner *et al.*, Z. Phys. **C33**, 1 (1986), and ISR data are from K. Alpgård *et al.*, Phys. Lett. **112B**, 193 (1982). CDF nonsingle-diffractive results at $\sqrt{s}$ = 630 and 1800 GeV are given in F. Abe *et al.*, Phys. Rev. **D41**, 2330 (1990). (Courtesy of D.R. Ward, Cambridge Univ., 1991.)

Average Hadron Multiplicities in e^+e^- Annihilation Events

Table 33.1: Average hadron multiplicity per e^+e^- annihilation event at $\sqrt{s} \approx 10$, 29–35, and 91 GeV. The rates given include decay products from resonances with $c\tau < 10$ cm, and include charge conjugated states. (Updated April 1994 by S. Bethke and O. Biebel.)

(a) Extrapolation to the unobserved region using the shape predicted by JETSET.

(b) The Standard Model branching ratio B($Z \to b\bar{b}$) = 0.220 was used.

(c) Mass of $\rho(770)$ determined to 757 ± 2 MeV/c^2. The reason for that is possibly the Bose-Einstein effect affecting the pions from the $\rho(770)$ decay.

(d) The value was taken from the cross section of the $\Lambda_c^+ \to p\pi K$, assuming the branching fraction to be (3.2$\pm$0.7)% (RPP 1992).

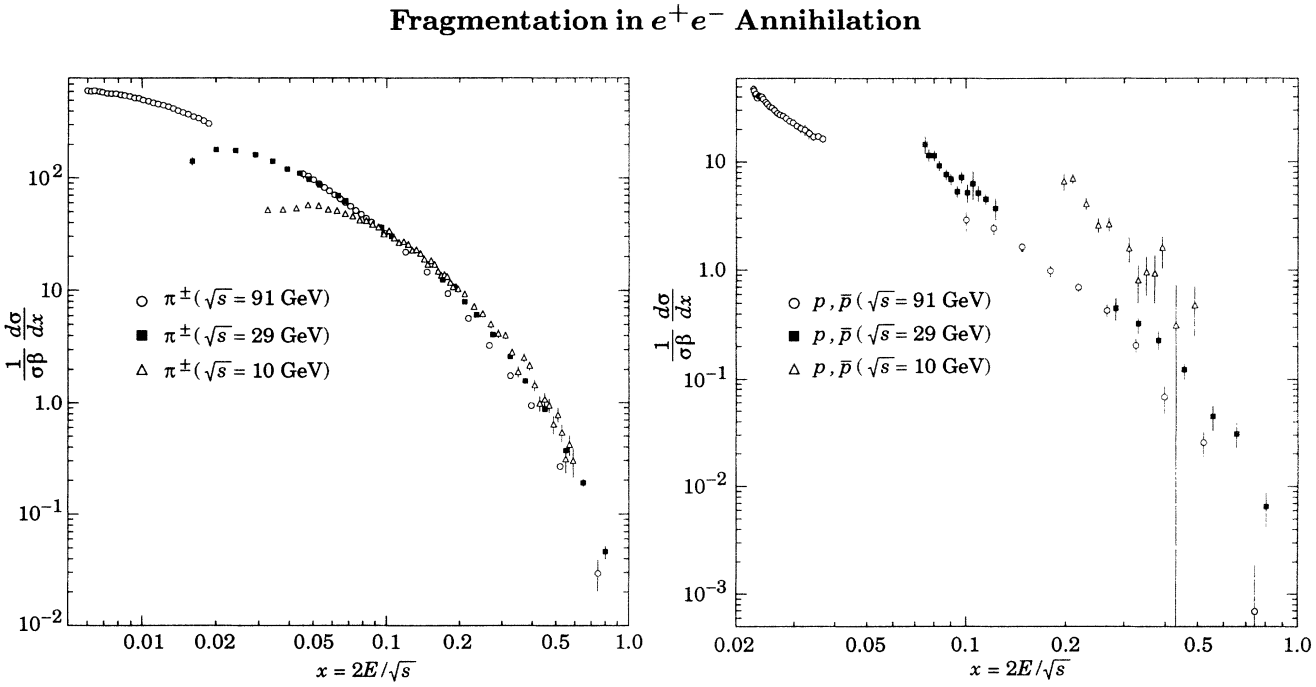

Figure 32.8: Fragmentation into $\pi^\pm$ in e^+e^- annihilations: Inclusive cross sections $(1/\sigma\beta)(d\sigma/dx)$, with $x = 2E/\sqrt{s}$. The indicated errors are statistical and systematic errors added in quadrature. △: rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8% [H. Albrecht *et al.* (ARGUS), Z. Phys. C44, 547 (1989)]. □: rate at $\sqrt{s} = 29$ GeV [**TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988)]. ○: rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV [**OPAL**—R. Akers *et al.*, CERN PPE/94-49 (1994)]. (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1994.)

Figure 32.9: Fragmentation into $p\bar{p}$ in e^+e^- annihilations: Inclusive cross sections $(1/\sigma\beta)(d\sigma/dx)$, with $x = 2E/\sqrt{s}$. The indicated errors are statistical and systematic errors added in quadrature. △: rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8%. This rate is obtained from the measured $\bar{p}$ rate by scaling with a factor of two [H. Albrecht *et al.* (ARGUS), Z. Phys. C44, 547 (1989)]. □: rate at $\sqrt{s} = 29$ GeV [**TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988)]. ○: rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV [**OPAL**—R. Akers *et al.*, CERN PPE/94-49 (1994)]. (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1994.)

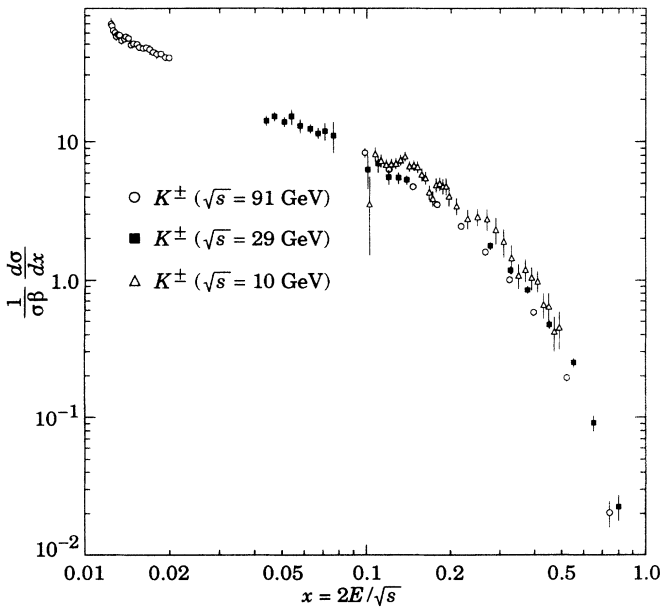

Figure 32.10: Fragmentation into $K^\pm$ in e^+e^- annihilations: Inclusive cross sections $(1/\sigma\beta)(d\sigma/dx)$, with $x = 2E/\sqrt{s}$. The indicated errors are statistical and systematic errors added in quadrature. △: rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8% [**ARGUS**—H. Albrecht *et al.*, Z. Phys. **C44**, 547 (1989)]. □: rate at $\sqrt{s} = 29$ GeV [**TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988)]. ○: rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV [**OPAL**—R. Akers *et al.*, CERN PPE/94-49 (1994)]. (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1994.)

Heavy Quark Fragmentation in e^+e^- Annihilation

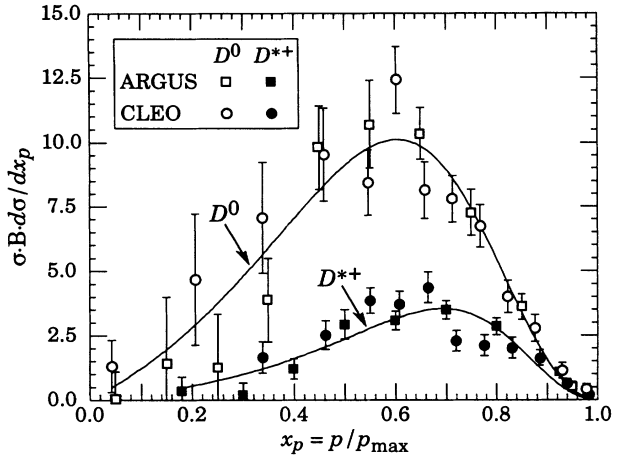

Figure 32.12: Heavy quark fragmentation: Shown are the CLEO (D. Bortoletto *et al.*, Phys. Rev. **D37**, 1719 (1988)) and ARGUS (H. Albrecht *et al.*, Z. Phys. **C52**, 353 (1991)) inclusive cross sections ($\sigma \cdot B \cdot d\sigma/dx_p$, with $x_p = p/p_{max}$) for the production of pseudoscalar D^0 and vector D^{*+} in e^+e^- annihilations at $\sqrt{s} \approx 10$ GeV. These inclusive spectra have not been corrected for cascades from higher states, nor for radiative effects. Many functional forms have been suggested to describe these "hard" spectra, characteristic of charmed particles produced in e^+e^- annihilations. The parameterization given by Peterson *et al.*, (Phys. Rev. **D27**, 105, (1983)) in terms of just one variable ϵ_p ($dN/dx_p = [x_p(1 - 1/x_p - \epsilon_p/(1 - x_p)]^{-2}$) has found the most use. Fits to the combined CLEO and ARGUS D^0 and D^{*+} data give $\epsilon_p(D^0) = 0.135 \pm 0.010$ and $\epsilon_p(D^*) = 0.078 \pm 0.008$; these are indicated by the solid curves.

Spin-dependent effects have been observed in, *e.g.*, the polarization of D^{*+} mesons as a function of x_p. Recent measurements of ϵ_p for D^{**} and D_{sJ} mesons by **CLEO**—J. Alexander *et al.*, Phys. Lett. **B303**, 377 (1993) and **ARGUS**—H. Albrecht *et al.*, Phys. Lett. **B221**, 422 (1989) and Phys. Lett. **B232**, 398, (1989) also indicate that the fragmentation functions of such orbitally excited charmed mesons are distinctly harder than for D or D^* mesons. How much of this is a mass effect and how much is truly a spin effect has not yet been fully determined. (Courtesy of D. Besson, Univ. of Kansas, 1994.)

Average e^+e^-, pp, and $\bar{p}p$ Multiplicity

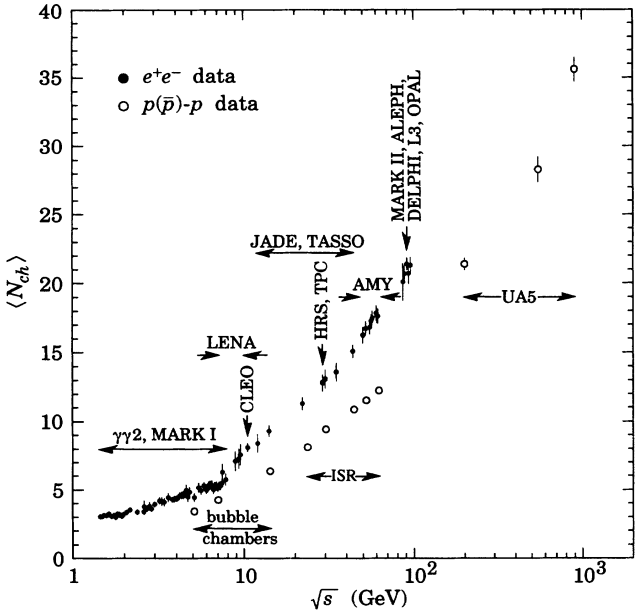

Figure 32.13: Average multiplicity as a a function of $\sqrt{s}$ for e^+e^- and $p\bar{p}$ annihilations and and pp collisions. The indicated errors are statistical and systematic errors added in quadrature, except when no systematic errors are given.
e^+e^-: All measurements include contributions from K^0_S and Λ decays. The $\gamma\gamma$2 and MARK I measurements contain a systematic 5% error. The five points at the Z resonance have been spread horizontally for clarity [**OPAL**—P.D. Acton *et al.*, Z. Phys. **C53**, 539 (1992) and references therein].
$p(\bar{p})$: The values measured by UA5 exclude single diffractive dissociation [J. Benecke *et al.* (bubble chamber), Nucl. Phys. **B76**, 29 (1976), W.M. Morse *et al.* (bubble chamber), Phys. Rev. **D15**, 66 (1977), **ISR**—A. Breakstone *et al.*, Phys. Rev. **D30**, 528 (1984), **UA5**—G.J. Alner *et al.*, Phys. Lett. **167B**, 476 (1986), **UA5**—Ansorge *et al.*, Z. Phys. **C43**, 357 (1989)]. (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1994.)

Annihilation Cross Section Near M_Z

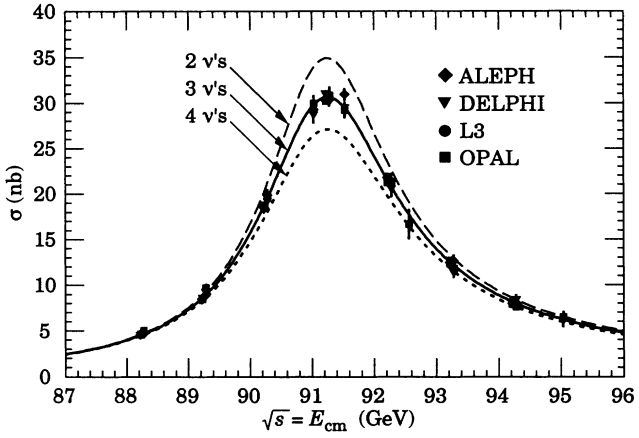

Figure 32.14: Data from the Mark II, ALEPH, DELPHI, L3, and OPAL Collaborations for the cross section in e^+e^- annihilation into hadronic final states as a function of c.m. energy near the Z. LEP detectors obtained data at the same energies; some of the points are obscured by overlap. The curves show the predictions of the Standard Model with three species (solid curve) and four species (dashed curve) of light neutrinos. The asymmetry of the curves is produced by initial-state radiation. References:

ALEPH: D. Decamp *et al.*, Z. Phys. **C53**, 1 (1992).
DEPHI: P. Abreu *et al.*, Nucl. Phys. **B367**, 511 (1992).
L3: B. Adeva *et al.*, Z. Phys. **C51**, 179 (1991).

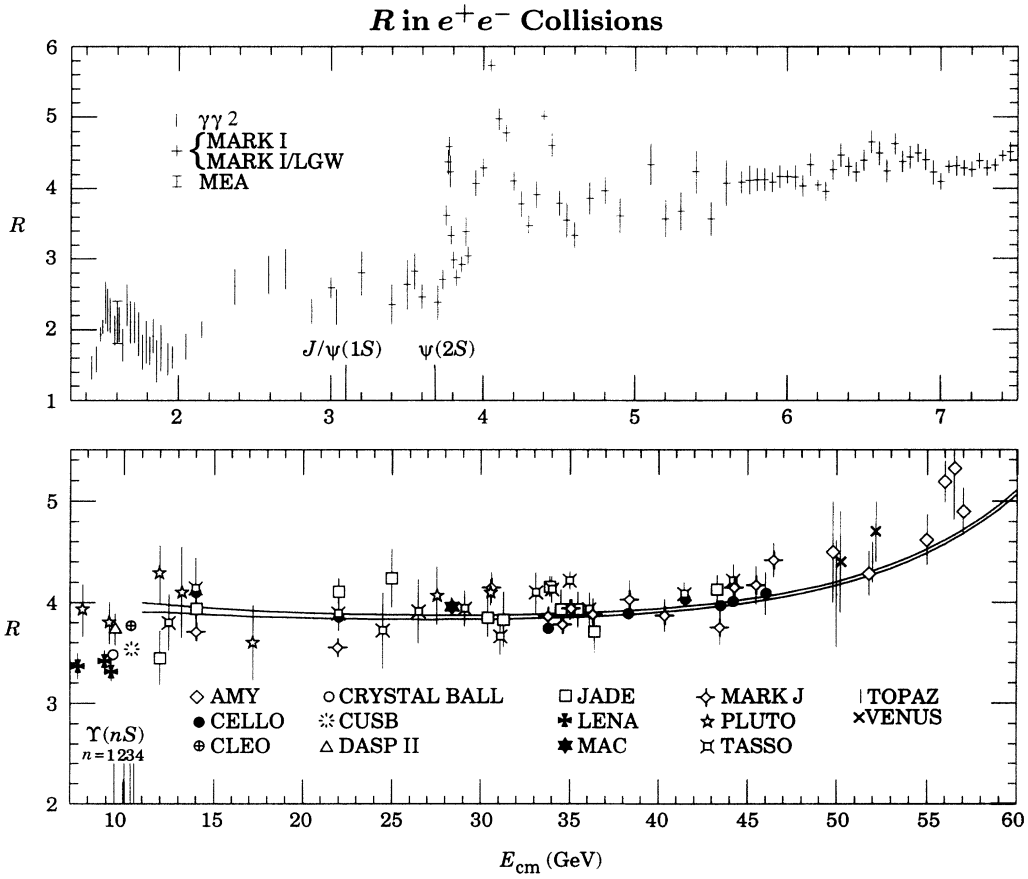

Figure 32.11: Selected measurements of $R \equiv \sigma(e^+e^- \to \text{hadrons})/\sigma(e^+e^- \to \mu^+\mu^-)$, where the annihilation in the numerator proceeds via one photon or via the Z. Measurements in the vicinity of the Z mass are shown in the following figure. The denominator is the calculated QED single-photon process; see the section on Cross-Section Formulae for Specific Processes. Radiative corrections and, where important, corrections for two-photon processes and τ production have been made. Note that the ADONE data ($\gamma\gamma 2$ and MEA) is for ≥ 3 hadrons. The points in the $\psi(3770)$ region are from the MARK I—Lead Glass Wall experiment. To preserve clarity only a representative subset of the available measurements is shown—references to additional data are included below. Also for clarity, some points have been combined or shifted slightly ($< 4\%$) in $E_{\rm cm}$, and some points with low statistical significance have been omitted. Systematic normalization errors are not included; they range from ~5–20%, depending on experiment. We caution that especially the older experiments tend to have large normalization uncertainties. Note the suppressed zero. The horizontal extent of the plot symbols has no significance. The positions of the $J/\psi(1S)$, $\psi(2S)$, and the four lowest Υ vector-meson resonances are indicated. Two curves are overlaid for $E_{\rm cm} > 11$ GeV, showing the theoretical prediction for R, including higher order QCD [M. Dine and J. Sapirstein, Phys. Rev. Lett. **43**, 668 (1979)] and electroweak corrections. The Λ values are for 5 flavors in the $\overline{\rm MS}$ scheme and are $\Lambda^{(5)}_{\overline{\rm MS}} = 60$ MeV (lower curve) and $\Lambda^{(5)}_{\overline{\rm MS}} = 250$ MeV (upper curve). Table 33.2: Regge theory provides a simple and compact description of total cross sections. It is sufficient to write $\sigma_{\text{total}} = X s^{\epsilon} + Y s^{-\eta}$, where the first term arises from pomeron exchange and the second from ρ, ω, f, a exchange. We list the results of A. Donnachie and P.V. Landshoff, Phys. Lett. **B296**, 227 (1992). Simultaneous fits were first made to pp and $\bar{p}p$ data for $\sqrt{s} > 10$ GeV, requiring the same values of X, ϵ, and η for both reactions. They obtained

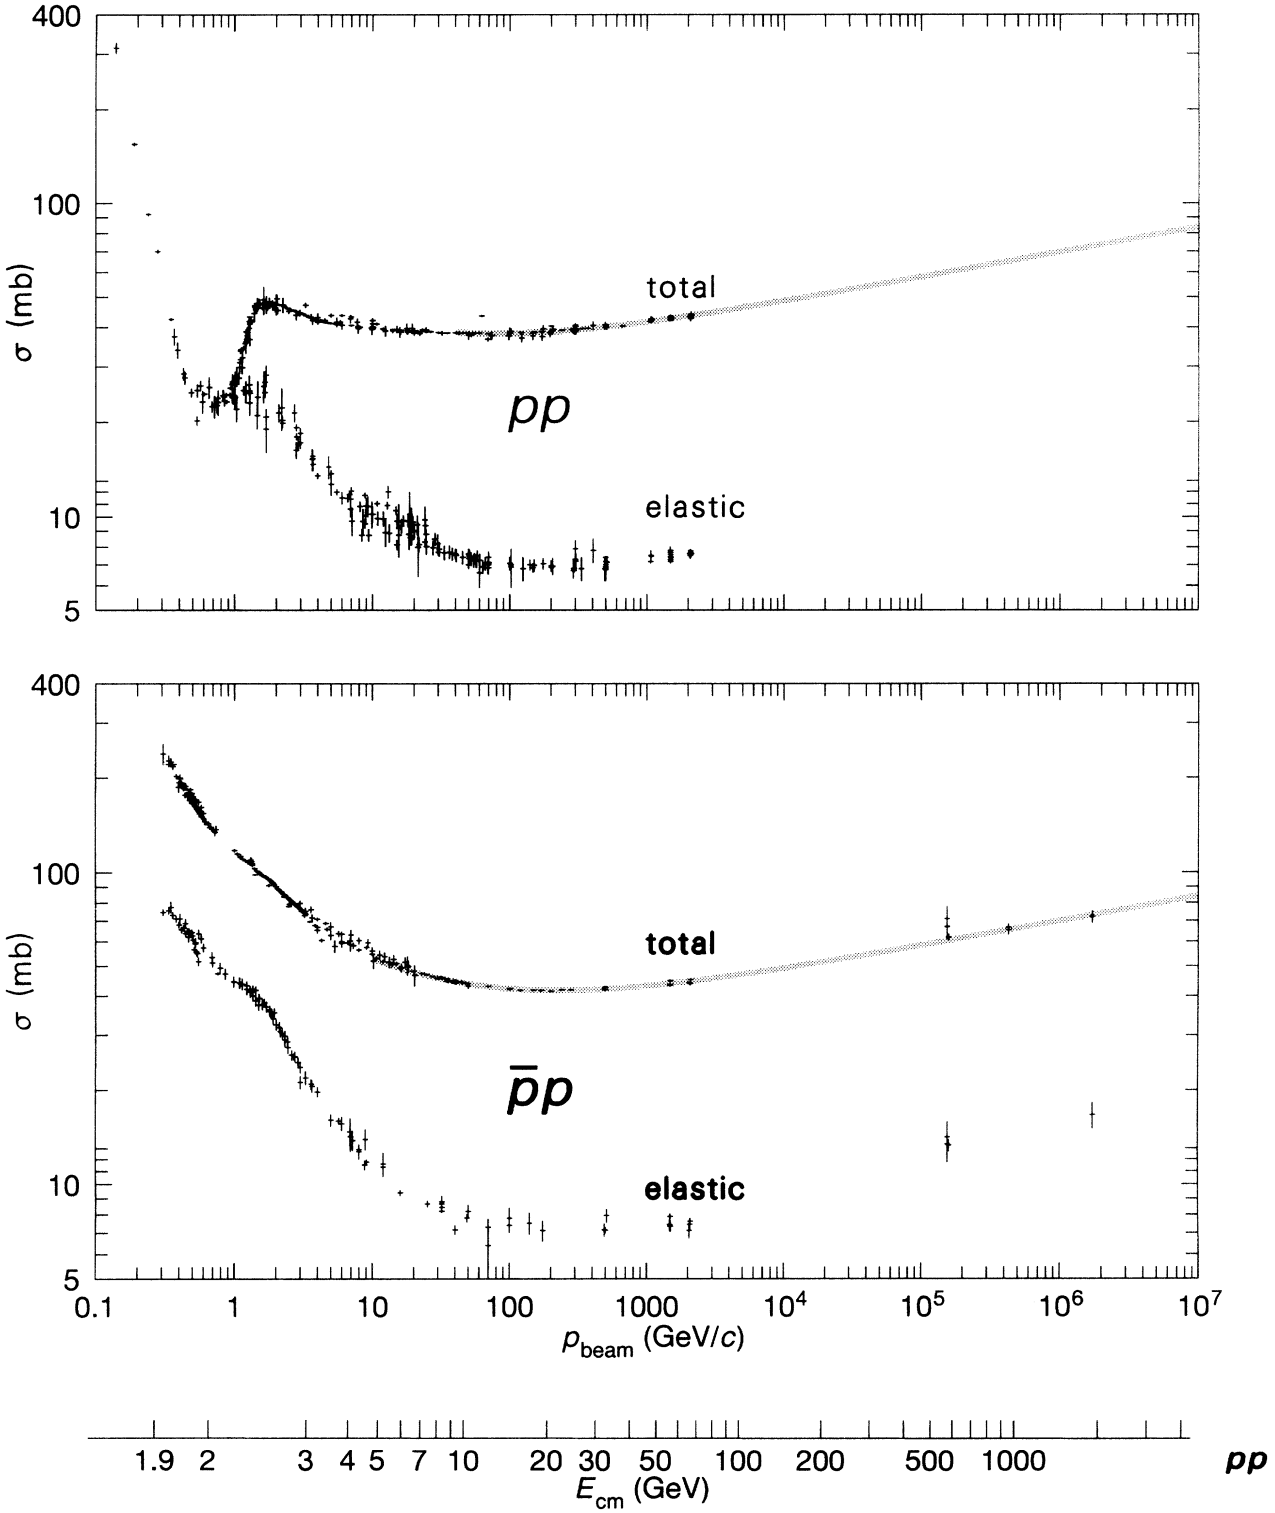
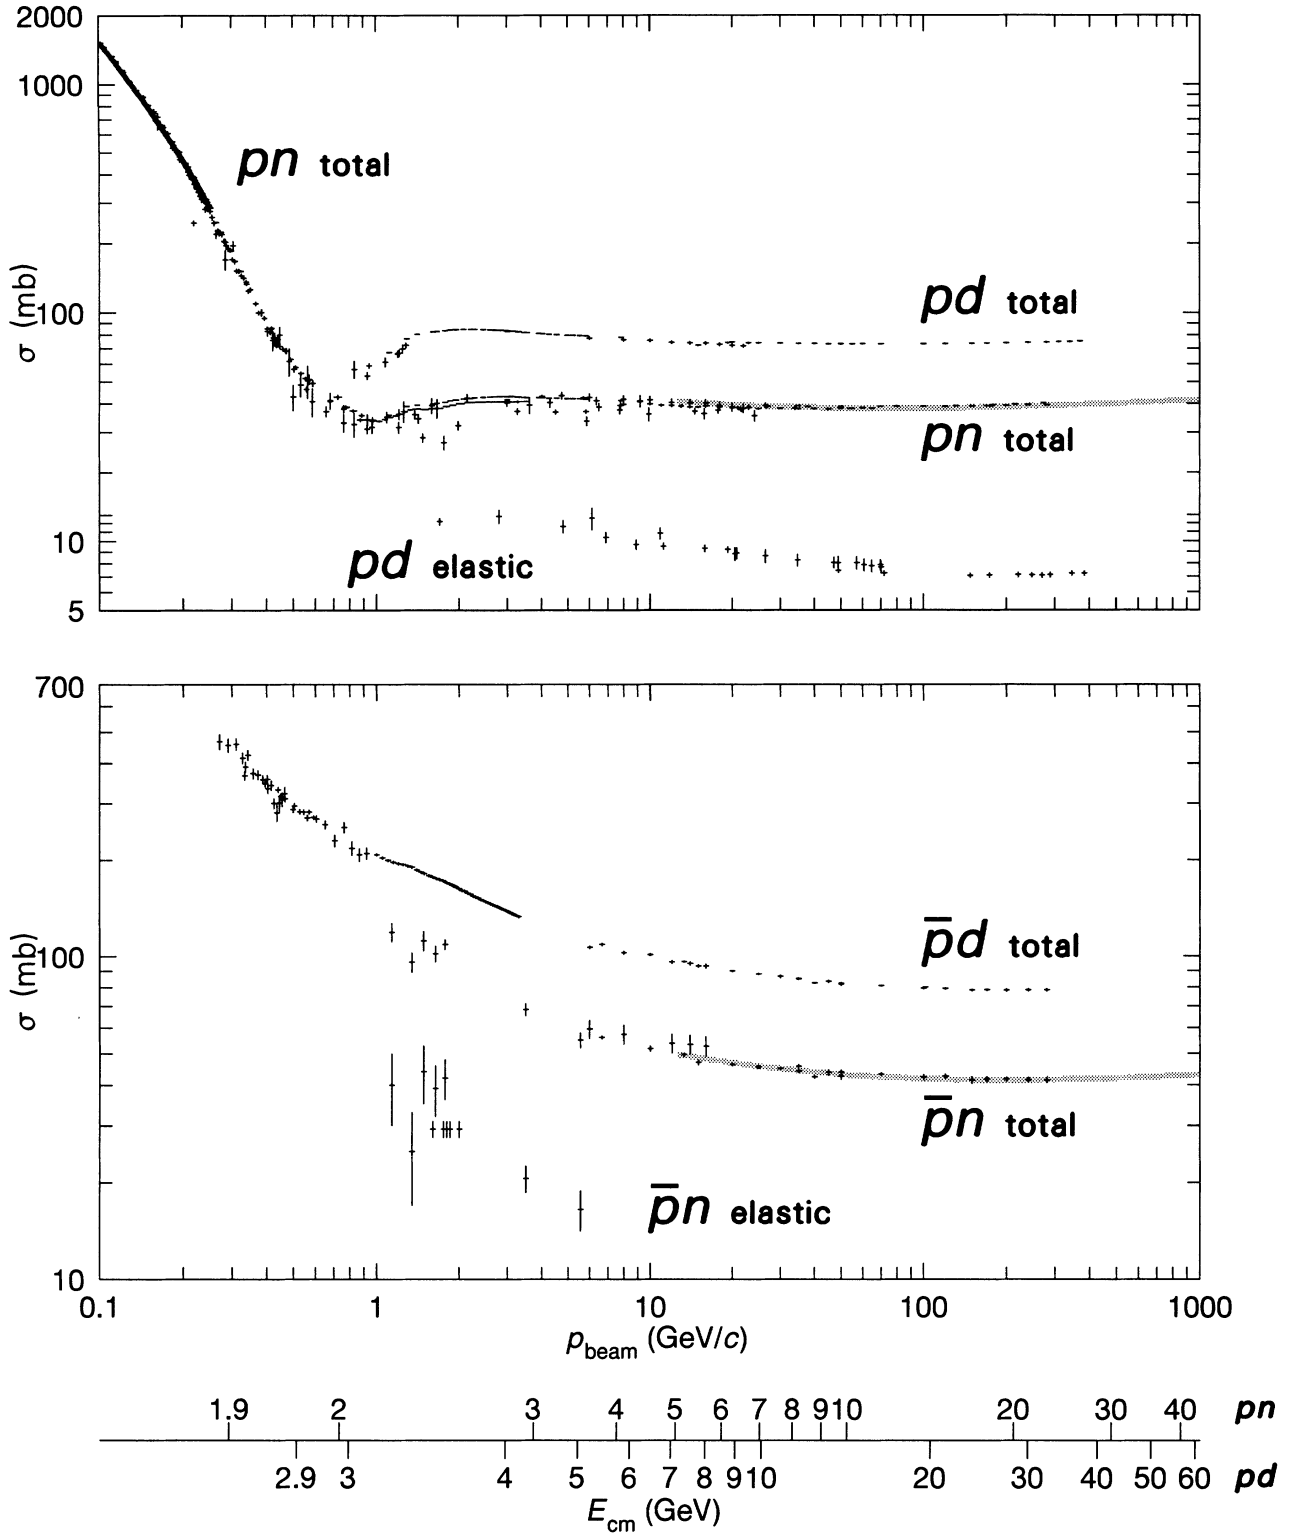
$$\epsilon = 0.0808 \qquad \eta = 0.4525 \ .$$



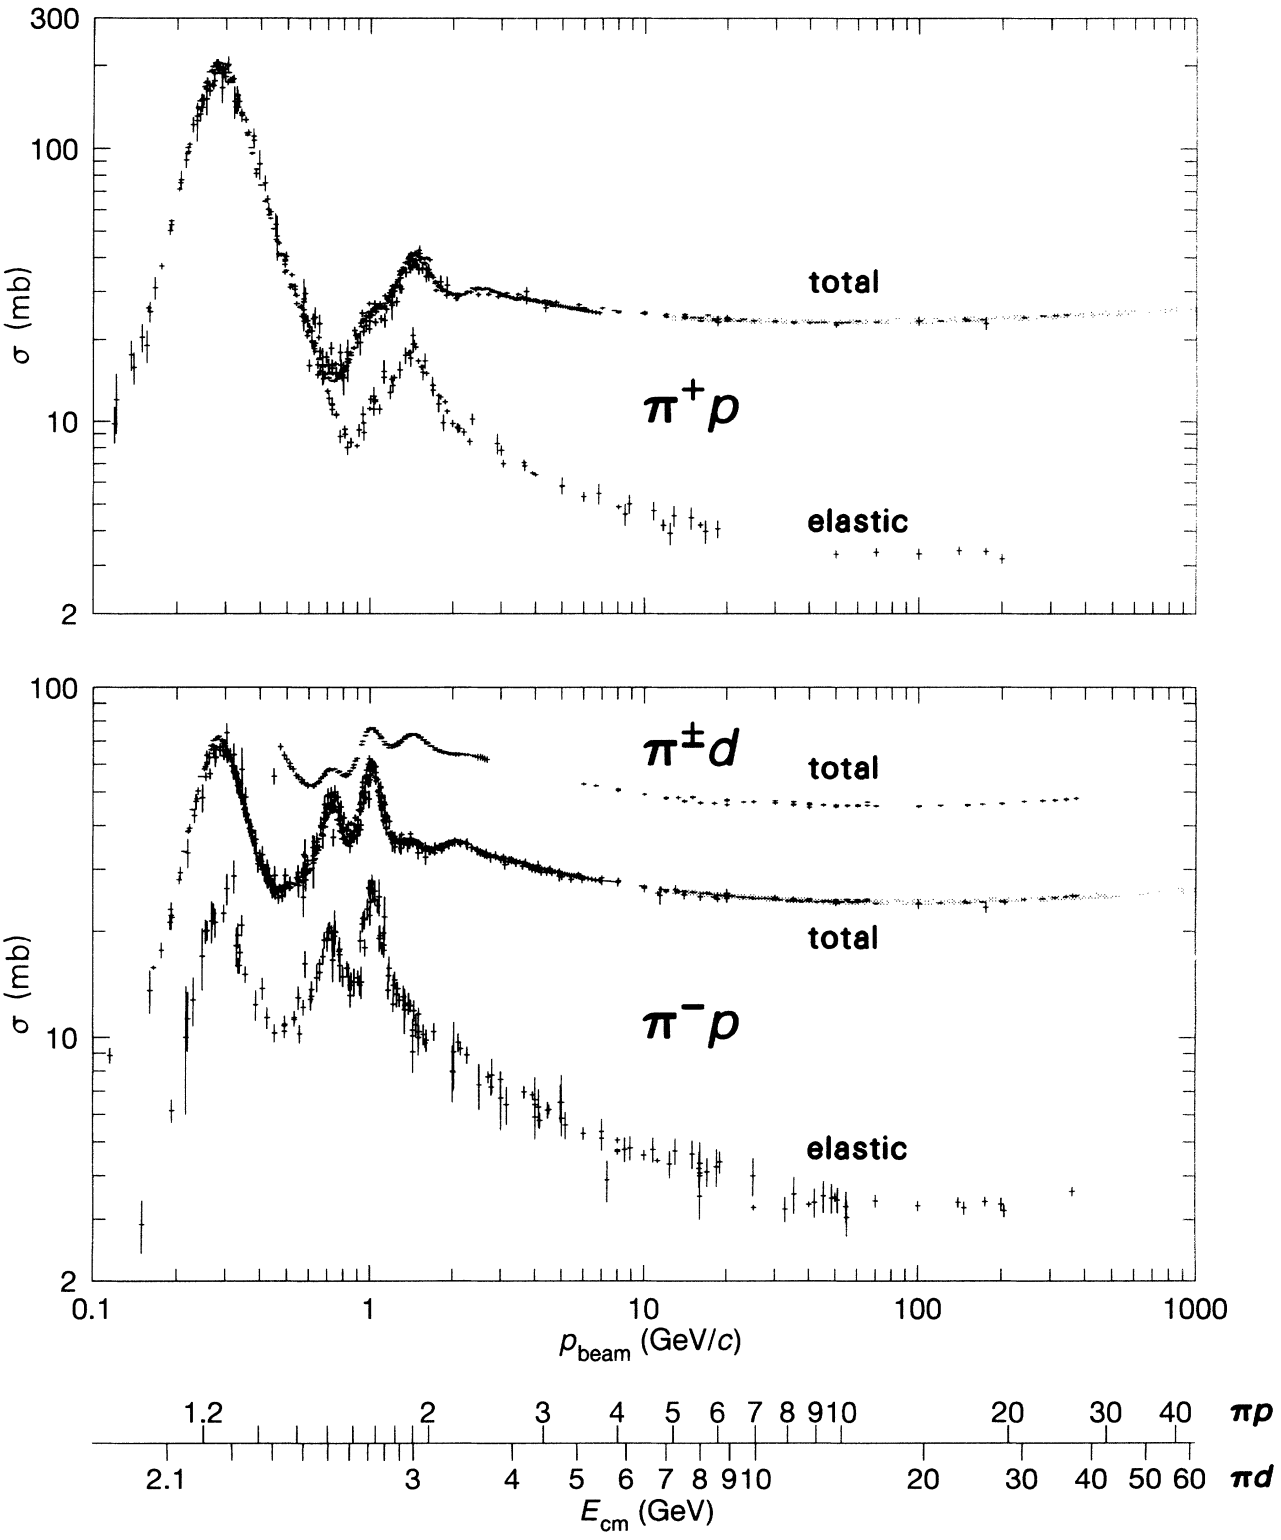
The same values of ϵ and η were used in fits to other reactions. For other pairs of reactions of the form ab and $a\bar{b}$, fits were made for a common value of X and a value of Y, using data with $\sqrt{s} > 6$ GeV. These fits are shown by the gray background curves on the following graphs.

Reaction	X (mb)	Y (mb)
$\bar{p}p$	21.70	98.39
pp	21.70	56.08
$\bar{p}n$	21.70*	92.71
pn	21.70*	54.77
$\pi^- p$	13.63	36.02
$\pi^+ p$	13.63	27.56
$K^- p$	11.82	26.36
$K^+ p$	11.82	8.15
γp	0.0677	0.129



*Requiring the same pomeron exchange coefficient as for $\sigma(pp)$ and $\sigma(\bar{p}p)$. Fits without the constraint result in an almost identical value, $X = 22.15$ mb.

Table 33.3: Extensively revised 1991 by A. Baldini, V. Flaminio, and O. Yushchenko. The CERN-HERA and COMPAS Groups have made least-squares fits to many high-energy cross sections. The parametrization is $\sigma(p) = A + Bp^n + C\ln^2(p) + D\ln(p)$, where σ is in mb and p is in GeV/c. The best-fit coefficients A, B, C, and D, and the exponent n are tabulated below; where indicated, not all the terms in $\sigma(p)$ are included in the fit. The errors on the parameters are highly correlated since the terms in $\sigma(p)$ are far from orthogonal. Also given is the range of momentum over which the fit was done; extrapolation outside this range is likely to give incorrect results.



Reaction	Momentum range (GeV/c)	Fitted parameters				
		A	B	n	C	D

INTRODUCTION TO THE FULL LISTINGS

Illustrative key 1343
Abbreviations 1344

Illustrative Key to the Full Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

Particle quantum numbers (where known).

Indicates particle omitted from Particle Properties Summary Table, implying particle's existence is not confirmed.

General comments on particle.

Quantity tabulated below.

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

"Document id" for this result; full reference given below.

Footnote number linking measurement to text of footnote.

Measurement technique. (See abbreviations on next page.)

Number of events *above background.*

Scale factor > 1 indicates possibly inconsistent data.

Measured value used in averages, fits, limits, etc.

Reaction producing particle, or general comments.

Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

"Change bar" indicates result added or changed since previous edition.

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Charge(s) of particle(s) detected.

Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian = ±error). See Introductory Text for discussion.

Top "data point" indicates average. Width of error bar (and shaded pattern below) is ±error on average, scaled by "scale factor" S.

Value and error for each experiment.

Contribution of experiment to χ^2 (if no entry present, experiment not used in calculating χ^2 or scale factor because of very large error).

Partial decay mode (labeled by Γ_i).

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

Branching ratio.

Our best value (and error) of quantity tabulated, as determined from constrained fit (using *all significant* measured branching ratios for this particle).

Weighted average of measurements of this ratio only.

Footnote (referring to LYNCH 81).

Branching ratio in terms of partial decay mode(s) Γ_i above.

Confidence level for measured upper limit.

References, ordered inversely by year, then author.

Partial list of author(s) in addition to first author.

"Document id" used on data entries above.

Quantum number determinations in this reference.

Journal, report, preprint, etc. (See abbreviations on next page.)

Institution(s) of author(s). (See abbreviations on next page.)

Indicator of Procedure Used to Obtain Our Result

OUR AVERAGE	From a weighted average of selected data.
OUR FIT	From a constrained or overdetermined multiparameter fit of selected data.
OUR EVALUATION	Not from a direct measurement, but evaluated from measurements of other quantities.
OUR ESTIMATE	Based on the observed range of the data. Not from a formal statistical procedure.
OUR LIMIT	For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

Measurement Techniques (i.e., Detectors and Methods of Analysis)

ACCM	ACCMOR Collaboration
AEMS	Argonne effective mass spectrometer
ALEP	ALEPH – CERN LEP detector
AMY	AMY detector at KEK-TRISTAN
ARG	ARGUS detector at DORIS
ARGD	Fit to semicircular amplitude path on Argand diagram
ASP	Anomalous single-photon detector
ASPK	Automatic spark chambers
ASTE	ASTERIX detector at LEAR
ASTR	Astronomy
B845	BNL experiment 845 detector
BAKS	Baksan underground scintillation telescope
BC	Bubble chamber
BDMP	Beam dump
BEBC	Big European bubble chamber at CERN
BES	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BIS2	BIS-2 spectrometer at Serpukhov
BKEI	BENKEI spectrometer system at KEK Proton Synchroton
BONA	Bonanza nonmagnetic detector at DORIS
BPWA	Barrelet-zero partial-wave analysis
CALO	Calorimeter
CBAL	Crystal Ball detector at SLAC-SPEAR or DORIS
CBAR	Crystal Barrel detector at CERN-LEAR
CBOX	Crystal Box at LAMPF
CC	Cloud chamber
CCFR	Columbia-Chicago-Fermilab-Rochester detector
CDF	Collider detector at Fermilab
CDHS	CDHS neutrino detector at CERN
CELL	CELLO detector at DESY
CHER	Cherenkov detector
CHM2	CHARM-II neutrino detector (glass) at CERN
CHRM	CHARM neutrino detector (marble) at CERN
CIBS	CERN-IHEP boson spectrometer
CLE2	CLEO II detector at CESR
CLEO	Cornell magnetic detector at CESR
CMD	Cryogenic magnetic detector at VEPP-2M, Novosibirsk
CNTR	Counters
COSM	Cosmology and astrophysics
CSB2	Columbia U. - Stony Brook BGO calorimeter inserted in NaI array
CUSB	Columbia U. - Stony Brook segmented NaI detector at CESR
D0	D0 detector at Fermilab Tevatron Collider
DASP	DESY double-arm spectrometer
DBC	Deuterium bubble chamber
DLCO	DELCO detector at SLAC-SPEAR or SLAC-PEP
DLPH	DELPHI detector at LEP
DM1	Magnetic detector no. 1 at Orsay DCI collider
DM2	Magnetic detector no. 2 at Orsay DCI collider
DPWA	Energy-dependent partial-wave analysis
E653	Fermilab E653 detector
E687	Fermilab E687 detector
E691	Fermilab E691 detector
E731	Fermilab E731 Spectrometer-Calorimeter
E761	Fermilab E761 detector
E799	Fermilab E799 Spectrometer-Calorimeter
EHS	Four-pi detector at CERN
ELEC	Electronic combination
EMC	European muon collaboration detector at CERN
EMUL	Emulsions
FBC	Freon bubble chamber
FIT	Fit to previously existing data
FMPS	Fermilab Multiparticle Spectrometer
FRAB	ADONE $B\overline{B}$ group detector
FRAG	ADONE $\gamma\gamma$ group detector
FRAM	ADONE MEA group detector
FREJ	FREJUS Collaboration – modular flash chamber detector (calorimeter)
GALX	GALLEX solar neutrino detector in the Gran Sasso Underground Lab.
GAM2	IHEP hodoscope Cherenkov γ calorimeter GAMS-2000
GAM4	CERN hodoscope Cherenkov γ calorimeter GAMS-4000
GOLI	CERN Goliath spectrometer
H1	H1 detector at DESY/HERA
HBC	Hydrogen bubble chamber
HDBC	Hydrogen and deuterium bubble chambers
HEBC	Helium bubble chamber
HEPT	Helium proportional tubes
HLBC	Heavy-liquid bubble chamber
HOME	Homestake underground scintillation detector
HPW	Harvard-Pennsylvania-Wisconsin detector
HRS	SLAC high-resolution spectrometer
HYBR	Hybrid: bubble chamber + electronics
IMB	Irvine-Michigan-Brookhaven underground Cherenkov detector
IMB3	Irvine-Michigan-Brookhaven underground Cherenkov detector
INDU	Magnetic induction
IPWA	Energy-independent partial-wave analysis
JADE	JADE detector at DESY
KAM2	KAMIOKANDE-II underground Cherenkov detector
KAMI	KAMIOKANDE underground Cherenkov detector
KOLR	Kolar Gold Field underground detector
L3	L3 detector at LEP
LASS	Large-angle superconducting solenoid spectrometer at SLAC
LEBC	Little European bubble chamber at CERN
LENA	Nonmagnetic lead-glass NaI detector at DORIS
MAC	MAC detector at PEP/SLAC
MBR	Molecular beam resonance technique
MCRO	MACRO detector in Gran Sasso
MD1	Magnetic detector at VEEP-4, Novosibirsk
MDRP	Millikan drop measurement
MICA	Underground mica deposits
MLEV	Magnetic levitation
MMS	Missing mass spectrometer
MPS	Multiparticle spectrometer at BNL
MPS2	Multiparticle spectrometer upgrade at BNL
MPSF	Multiparticle spectrometer at Fermilab
MPWA	Model-dependent partial-wave analysis
MRK1	SLAC Mark-I detector
MRK2	SLAC Mark-II detector
MRK3	SLAC Mark-III detector
MRKJ	Mark-J detector at DESY
MRS	Magnetic resonance spectrometer
NA14	CERN
NA31	CERN NA31 Spectrometer-Calorimeter
NA32	CERN NA32 Spectrometer
ND	NaI detector at VEPP-2M, Novosibirsk
NICE	Serpukhov nonmagnetic precision spectrometer
NMR	Nuclear magnetic resonance
NUSX	Mont Blanc NUSEX underground detector
OBLX	OBELIX detector at LEAR
OLYA	Detector at VEPP-2M and VEPP-4, Novosibirsk
OMEG	CERN OMEGA spectrometer
OPAL	OPAL detector at LEP
OSPK	Optical spark chamber
PLAS	Plastic detector
PLUT	DESY PLUTO detector
PWA	Partial-wave analysis
REDE	Resonance depolarization
RVUE	Review of previous data
SAGE	US - Russian Gallium Experiment
SFM	CERN split-field magnet
SHF	SLAC Hybrid Facility Photon Collaboration
SIGM	Serpukhov CERN-IHEP magnetic spectrometer (SIGMA)
SILI	Silicon detector
SLD	SLC Large Detector for e^+e^- colliding beams at SLAC
SOUD	Soudan underground detector
SPEC	Spectrometer
SPED	From maximum of speed plot or resonant amplitude
SPRK	Spark chamber
SQID	SQUID device
STRC	Streamer chamber
TASS	DESY TASSO detector

Abbreviations Used in the Full Listings *(Cont'd)*

THEO	Theoretical or heavily model-dependent result
THY	Theory
TOF	Time-of-flight
TOPZ	TOPAZ detector at KEK-TRISTAN
TPC	TPC detector at PEP/SLAC
TPS	Tagged photon spectrometer at Fermilab
TRAP	Penning trap
UA1	UA1 detector at CERN
UA2	UA2 detector at CERN
UA5	UA5 detector at CERN
VES	Vertex Spectrometer Facility at 70 GeV IHEP accelerator
VNS	VENUS detector at KEK-TRISTAN
WA75	CERN WA75 experiment
WA82	CERN WA82 experiment
WIRE	Wire chamber
XEBC	Xenon bubble chamber
ZEUS	ZEUS detector at DESY/HERA

Conferences

Conferences are generally referred to by the location at which they were held (e.g., HAMBURG, TORONTO, CORNELL, BRIGHTON, etc.).

Journals

AA	Astronomy and Astrophysics
ADVP	Advances in Physics
AFIS	Anales de Fisica
AJP	American Journal of Physics
ANP	Annals of Physics
ANPL	Annals of Physics (Leipzig)
ANYAS	Annals of the New York Academy of Sciences
AP	Atomic Physics
APAH	Acta Physica Academiae Scientiarum Hungaricae
APJ	Astrophysical Journal
APP	Acta Physica Polonica
ARNPS	Annual Review of Nuclear and Particle Science
ARNS	Annual Review of Nuclear Science
BAPS	Bulletin of the American Physical Society
BASUP	Bulletin of the Academy of Science, USSR (Physics)
CJP	Canadian Journal of Physics
CNPP	Comments on Nuclear and Particle Physics
CZJP	Czechoslovak Journal of Physics
DANS	Doklady Akademii nauk SSSR
EPL	Europhysics Letters
FECAY	Fizika Elementarnykh Chastits i Atomnogo Yadra
HADJ	Hadronic Journal
IJMP	International Journal of Modern Physics
JAP	Journal of Applied Physics
JETP	English Translation of Soviet Physics ZETF
JETPL	English Translation of Soviet Physics ZETF Letters
JINR	Joint Inst. for Nuclear Research
JPA	Journal of Physics, A
JPB	Journal of Physics, B
JPCRD	Journal of Physical and Chemical Reference Data
JPG	Journal of Physics, G
JPSJ	Journal of the Physical Society of Japan
LNC	Lettere Nuovo Cimento
MNRA	Monthly Notices of the Royal Astronomical Society
MPL	Modern Physics Letters
NAT	Nature
NC	Nuovo Cimento
NIM	Nuclear Instruments and Methods
NP	Nuclear Physics
NPBPS	Nuclear Physics B Proceedings Supplement
PDAT	Physik Daten
PL	Physics Letters
PN	Particles and Nuclei
PPN	Physics of Particles and Nuclei (formerly SJPN)
PPNP	Progress in Particles and Nuclear Physics
PPSL	Proc. of the Physical Society of London
PR	Physical Review
PRAM	Pramana
PRL	Physical Review Letters
PRPL	Physics Reports (Physics Letters C)
PRSE	Proc. of the Royal Society of Edinburgh
PRSL	Proc. of the Royal Society of London, Section A
PS	Physica Scripta
PTP	Progress of Theoretical Physics
PTRSL	Phil. Trans. Royal Society of London
RA	Radiochimica Acta
RMP	Reviews of Modern Physics
RNC	La Rivista del Nuovo Cimento
RPP	Reports on Progress in Physics
RRP	Revue Roumaine de Physique
SCI	Science
SJNP	Soviet Journal of Nuclear Physics
SJPN	Soviet Journal of Particles and Nuclei
SPD	Soviet Physics Doklady (Magazine)
SPU	Soviet Physics - Uspekhi
YAF	Yadernaya Fizika
ZETF	Zhurnal Eksperimental'noi i Teoreticheskoi Fiziki
ZETFP	Zhurnal Eksperimental'noi i Teoreticheskoi Fiziki, Pis'ma v Redakts
ZNAT	Zeitschrift fur Naturforschung
ZPHY	Zeitschrift fur Physik

Institutions

AACH	Phys. Inst. der Techn. Hochschule **Aachen** (Historical, use for general Inst. der Techn. Hochschule)	Aachen, Germany
AACH1	I Phys. Inst. der Techn. Hochschule **Aachen**	Aachen, Germany
AACH3	III Phys. Inst. der Techn. Hochschule **Aachen**	Aachen, Germany
AACHT	Institut für Theoretische Physik	**Aachen**, Germany
AARH	**Aarhus** Univ.	Aarhus C, Denmark
ABO	**Åbo** Akademi University	Åbo (Turku), Finland
ADEL	**Adelphi** Univ.	Garden City, NY, USA
ADLD	The Univ. of **Adelaide**	South Australia, Australia
AERE	Atomic Energy Research Estab.	Didcot, United Kingdom
AFRR	**Armed Forces** Radiobiology Res. Inst.	Bethesda, MD, USA
AHMED	Physical Research Lab.	**Ahmedabad**, Gujarat, India
AICH	**Aichi** Univ. of Education	Aichi, Japan
AKIT	**Akita** Univ.	Akita, Japan
ALAH	Univ. of **Alabama (Huntsville)**	Huntsville, AL, USA
ALAT	Univ. of **Alabama (Tuscaloosa)**	Tuscaloosa, AL, USA
ALBA	**SUNY at Albany**	Albany, NY, USA
ALBE	Univ. of **Alberta**	Edmonton, AB, Canada
AMES	**Ames Lab.**	Ames, IA, USA
AMHT	**Amherst** College	Amherst, MA, USA
AMST	Univ. van **Amsterdam**	Amsterdam, The Netherlands
ANIK	NIKHEF	**Amsterdam**, The Netherlands
ANKA	**Middle East** Technical Univ.	Ankara, Turkey
ANL	**Argonne** National Lab.	Argonne, IL, USA
ANSM	**St. Anselm** Coll.	Manchester, NH, USA
ARCBO	**Arecibo** Observatory	Arecibo, PR, USA
ARIZ	Univ. of **Arizona**	Tucson, AZ, USA
ARZS	**Arizona State** Univ.	Tempe, AZ, USA
ASCI	Academy of Sciences	**Moscow**, Russian Federation
AST	**Inst. of Phys.**	Nankang, Taipei, The Republic of China (Taiwan)
ATEN	NCSR **"Demokritos"**	**Aghia** Paraskevi Attikis, Greece
ATHU	Univ. of **Athens**	Athens, Greece
AUCK	Univ. of **Auckland**	Auckland, New Zealand
BAKU	Inst. of Physics	**Baku**, Azerbaijan
BANGB	**Bangabasi** College	Calcutta, India
BARC	Univ. Autónoma de **Barcelona**	Bellaterra (Barcelona), Spain
BARI	Univ. di **Bari**	Bari, Italy
BART	Univ. of **Delaware**; **Bartol** Research Inst.	Newark, DE, USA
BASL	Inst. für Physik der Univ. **Basel**	Basel, Switzerland
BAYR	Univ. **Bayreuth**	Bayreuth, Germany
BCEN	Centre d'Etudes Nucleaires de **Bordeaux-Gradignan**	Gradignan, France
BELG	Inter-University Inst. for High Energies (ULB-VUB)	**Bruxelles**, Belgium

Abbreviations Used in the Full Listings *(Cont'd)*

BELL	AT & T **Bell** Labs	Murray Hill, NJ, USA
BERG	Univ. of **Bergen**	Bergen, Norway
BERL	**DESY** - Inst. für Hochenergiephysik Zeuthen	**Zeuthen**, Germany
BERN	Univ. of **Berne**	Berne, Switzerland
BGNA	Univ. di **Bologna**	Bologna, Italy
BGUN	**Ben-Gurion** Univ.	Beer-Sheva, Israel
BHAB	**Bhabha Atomic** Research Center	Trombay, Bombay, India
BHEP	**Inst. of High Energy Physics**	**Beijing**, The People's Republic of China
BIEL	Univ. **Bielefeld**	Bielefeld, Germany
BING	**SUNY at Binghamton**	Binghamton, NY, USA
BIRM	Univ. of **Birmingham**	Edgbaston, Birmingham, United Kingdom
BLSU	**Bloomsburg** Univ.	Bloomsburg, PA, USA
BNL	**Brookhaven National Lab.**	Upton, NY, USA
BOCH	**Ruhr** Univ. **Bochum**	Bochum, Germany
BOHR	**Niels Bohr Inst.**	Copenhagen Ø, Denmark
BOIS	**Boise** State Univ.	Boise, ID, USA
BOMB	Univ. of **Bombay**	Bombay, India
BONN	Univ. **Bonn**	Bonn, Germany
BORD	Univ. de **Bordeaux** I	Gradignan, France
BOSE	S.N. **Bose** National Centre for Basis Sciences	Calcutta, India
BOSK	**"Rudjer Bošković"** Inst.	Zagreb, Croatia
BOST	**Boston** Univ.	Boston, MA, USA
BRAN	**Brandeis** Univ.	Waltham, MA, USA
BRCO	Univ. of **British Columbia**	Vancouver, BC, Canada
BRIS	Univ. of **Bristol**	Bristol, United Kingdom
BROW	**Brown** Univ.	Providence, RI, USA
BRUX	Univ. Libre de **Bruxelles**; Service de Physique des Particules Elémentaires	Bruxelles, Belgium
BRUXT	Univ. Libre de **Bruxelles**; Physique Théorique	Bruxelles, Belgium
BUCH	Univ. of **Bucharest**	Bucharest-Magurele, Romania
BUDA	KFKI Research Inst. for Particle & Nuclear Physics	**Budapest**, Hungary
BUFF	**SUNY at Buffalo**	Buffalo, NY, USA
BURE	Inst. des Hautes Etudes Scientifiques	**Bures-sur-Yvette**, France
CAEN	Lab. de Physique Corpusculaire, **ISMRA**	**CAEN**, France
CAGL	Univ. di **Cagliari**	Cagliari, Italy
CAIR	**Cairo** University	Orman, Giza, Cairo, Egypt
CAIW	**Carnegie Inst.** of Washington	Washington, DC, USA
CALC	Univ. of **Calcutta**	Calcutta, India
CAMB	Univ. of **Cambridge**	Cambridge, United Kingdom
CAMP	Univ. de **Campinas**	**Campinas**, SP, Brasil
CANB	**Australian National Univ.**	Canberra, ACT, Australia
CAPE	University of **Capetown**	Rondebosch, Cape, South Africa
CARA	Univ. Central de **Venezuela**	Caracas, Venezuela
CARL	**Carleton** Univ.	Ottawa, ON, Canada
CARLC	**Carleton** College	Northfield, MN, USA
CASE	**Case** Western Reserve Univ.	Cleveland, OH, USA
CAST	**China** Center of Advanced Science and Technology	Beijing, The People's Republic of China
CATA	Univ. di **Catania**	Catania, Italy
CATH	**Catholic** Univ. of America	Washington, DC, USA
CAVE	Univ. of Cambridge	Cambridge, United Kingdom
CBNM	CBNM	**Geel**, Belgium
CCAC	**Allegheny** College	Meadville, PA, USA
CDEF	**College de France**	Paris, France
CEA	Cambridge Electron Accelerator (Historical in *Review*)	**Cambridge, MA**, USA
CENG	Centre d'Etudes Nucleaires	**Grenoble**, France
CERN	**CERN**, European Laboratory for Particle Physics	Genève, Switzerland
CFPA	Univ. of **California, Berkeley**)	Berkeley, CA, USA
CHIC	Univ. of **Chicago**	Chicago, IL, USA
CINC	Univ. of **Cincinnati**	Cincinnati, OH, USA
CINV	CINVESTAV-IPN, Centro de Investigacion y de Estudios Avanzados del IPN	**México**, DF, Mexico
CIT	**California Inst. of Tech.**	Pasadena, CA, USA
CLER	Univ. de **Clermont-Ferrand**	Aubière, France
CLEV	**Cleveland** State Univ.	Cleveland, OH, USA
CMNS	**Comenius** Univ.	**Bratislava**, Slovak Republic
CMU	**Carnegie Mellon** Univ.	Pittsburgh, PA, USA
CNEA	**Comisión Nacional de Energía Atómica**	Buenos Aires, Argentina
CNRC	Centre for Research in Particle Physics	Ottawa, ON, Canada
CNRS	Centre National de la Recherche Scientifique, Luminy	**Marseille**, France
COLO	Univ. of **Colorado**	Boulder, CO, USA
COLU	**Columbia** Univ.	New York, NY, USA
CONC	**Concordia** University	Montreal, PQ, Canada
CORN	**Cornell** Univ.	Ithaca, NY, USA
COSU	**Colorado State** Univ.	Fort Collins, CO, USA
CRAC	**Kraków** Inst. of Nuclear Physics	Kraków, Poland
CRNL	**Chalk River** Labs.	Chalk River, ON, Canada
CSOK	**Oklahoma** Central State Univ.	Edmond, OK, USA
CSULB	**California** State Univ.	Long Beach, CA, USA
CUNY	**City College** of **New York**	New York, NY, USA
CURIN	**Univ. Pierre et Marie Curie** (Paris VI), LPNHE	Paris, France
CURIT	**Univ. Pierre et Marie Curie** (Paris VI), LPTHE	Paris, France
DALH	**Dalhousie** Univ.	Halifax, NS, Canada
DARE	**Daresbury** Lab	Cheshire, United Kingdom
DARM	Tech. Hochschule **Darmstadt**	Darmstadt, Germany
DELA	Univ. of **Delaware**; Dept. of Physics & Astronomy	Newark, DE, USA
DELH	Univ. of **Delhi**	Delhi, India
DESY	**DESY**, Deutsches Elektronen-Synchrotron	Hamburg, Germany
DOE	**Department of Energy**	Washington, DC, USA
DORT	Univ. **Dortmund**	Dortmund, Germany
DUKE	**Duke** Univ.	Durham, NC, USA
DURH	Univ. of **Durham**	Durham City, United Kingdom
DUUC	**University** College	Dublin, Ireland
EDIN	Univ. of **Edinburgh**	Edinburgh, United Kingdom
EFI	**Enrico Fermi Inst.**	**Chicago**, IL, USA
ELMT	**Elmhurst** College	Elmhurst, IL, USA
ENSP	**l'Ecole Normale Supérieure**	**Paris**, France
EOTV	**Eötvös** University	Budapest, Hungary
EPOL	**École Polytechnique**	**Palaiseau**, France
ERLA	Univ. **Erlangen-Nurnberg**	Erlangen, Germany
ETH	Inst. for High Energy Physics	**Zürich**, Switzerland
FERR	Univ. di **Ferrara**	Ferrara, Italy
FIRZ	Univ. di **Firenze**	Firenze, Italy
FISK	**Fisk** Univ.	Nashville, TN, USA
FLOR	Univ. of **Florida**	Gainesville, FL, USA
FNAL	**Fermilab**	Batavia, IL, USA
FOM	**FOM**, Stichting voor Fundamenteel Onderzoek der Materie	JP **Utrecht**, The Netherlands
FRAN	Univ. **Frankfurt**	Frankfurt am Main, Germany
FRAS	Lab. Nazionali de **Frascati** dell'INFN	Frascati (Roma), Italy
FREIB	**Albert-Ludwigs** Univ.	**Freiburg**, Germany
FREIE	**Freie Univ. Berlin**	Berlin, Germany
FRIB	Univ. de **Fribourg**	Fribourg, Switzerland
FSU	**Florida State** University	Tallahassee, FL, USA
FSUSC	**Florida State** Univ.	Tallahassee, FL, USA
FUKI	**Fukui** Univ.	Fukui, Japan
FUKU	**Fukushima** Univ.	Fukushima, Japan
GENO	Univ. di **Genova**	Genova, Italy
GEOR	**Georgian Academy of Sciences**	Tbilisi, Republic of Georgia
GESC	**General Electric** Co.	Schenectady, NY, USA
GEVA	Univ. de **Genève**	Genève, Switzerland
GIFU	**Gifu** Univ.	Gifu, Japan
GLAS	Univ. of **Glasgow**	Glasgow, United Kingdom
GMAS	**George Mason** Univ.	Fairfax, VA, USA
GOET	Univ. **Göttingen**	Göttingen, Germany

Abbreviations Used in the Full Listings *(Cont'd)*

GRAN	Univ. de **Granada**	Granada, Spain
GRAZ	Univ. **Graz**	Graz, Austria
GRON	Univ. of **Groningen**	Groningen, The Netherlands
GSCO	**Geological Survey of Canada**	Ottawa, ON, Canada
GSI	**Darmstadt Gesellschaft** fur Schwerionenforschung	Darmstadt, Germany
GUEL	Univ. of **Guelph**	Guelph, ON, Canada
GWU	**George Washington** Univ.	Washington, DC, USA
HAIF	**Technion** – Israel Inst. of Tech.	Technion, Haifa, Israel
HAMB	Univ. **Hamburg**	Hamburg, Germany
HANN	Univ. **Hannover**	Hannover, Germany
HARC	**Houston Advanced Research Ctr.**	The Woodlands, TX, USA
HARV	**Harvard** Univ.	Cambridge, MA, USA
HAWA	Univ. of **Hawai'i**	Honolulu, HI, USA
HEBR	**Hebrew** Univ.	Jerusalem, Israel
HEID	Univ. **Heidelberg**; (unspecified division) (Historical in *Review*)	Heidelberg, Germany
HEIDH	Univ. **Heidelberg**; Inst. für Hochenergiephysik	Heidelberg, Germany
HEIDP	Univ. **Heidelberg**; Physik Inst.	Heidelberg, Germany
HEIDT	Univ. **Heidelberg**; Inst. für Theoretische Physik	Heidelberg, Germany
HELS	Univ. of **Helsinki**	Helsinki, Finland
HIRO	**Hiroshima** Univ.	Higashi-Hiroshima, Japan
HOUS	Univ. of **Houston**	Houston, TX, USA
HPC	**Hewlett-Packard** Corp.	Cupertino, CA, USA
HSCA	**Harvard-Smithsonian** Center for Astrophysics	Cambridge, MA, USA
IAS	**Inst. for Advanced Study**	Princeton, NJ, USA
IASD	**Dublin** Inst. for Advanced Studies	Dublin, Ireland
IBAR	**Ibaraki** Univ.	Ibaraki, Japan
IBM	**IBM** Corp.	Palo Alto, CA, USA
IBMY	**IBM**	Yorktown Heights, NY, USA
IBS	Inst. for **Boson Studies**	Pasadena, CA, USA
ICEPP	Univ. of **Tokyo**; Int. Center for Elementary Particle Physics (ICEPP)	Tokyo, Japan
ICRR	Univ. of **Tokyo**; **Inst. for Cosmic Ray Research**	Tokyo, Japan
ICTP	Int'l Centre for Theoretical Physics	**Trieste**, Italy
IFIC	Univ. de **Valencia** – CSIC	Burjassot, Valencia, Spain
IFRJ	Univ. Federal do **Rio de Janeiro**	Rio de Janeiro, RJ, Brasil
IIT	**Illinois Inst. of Tech.**	Chicago, IL, USA
ILL	Univ. of **Illinois at Urbana-Champaign**	Urbana, IL, USA
ILLC	Univ. of **Illinois at Chicago**	Chicago, IL, USA
ILLG	Inst. **Laue-Langevin**	Grenoble, France
IND	**Indiana** Univ.	Bloomington, IN, USA
INEL	E G and G **Idaho**, Inc.	Idaho Falls, ID, USA
INFN	Ist. Nazionale di Fisica Nuclear (Generic INFN, unknown location)	Various places, Italy
INNS	Univ. **Innsbruck**	Innsbruck, Austria
INRM	**INR**, Inst. for Nucl. Research	**Moscow**, Russian Federation
INUS	Univ. of **Tokyo**; **Inst. for Nuclear Study**	Tokyo, Japan
IOAN	Univ. of **Ioannina**	Ioannina, Greece
IOFF	A.F. **Ioffe** Phys. Tech. Inst.	St. **Petersburg**, Russian Federation
IOWA	Univ. of **Iowa**	Iowa City, IA, USA
IPN	**IPN**, Inst. de Phys. Nucl.	**Orsay**, France
IPNP	Univ. Pierre et Marie Curie (**Paris** VI)	Paris, France
IRAD	Inst. du Radium (Historical)	**Paris**, France
ISNG	Inst. des Sciences Nucleaires (ISN)	**Grenoble**, France
ISU	**Iowa State** Univ.	Ames, IA, USA
ITEP	**ITEP**, Inst. of Theor. and Exp. Physics	Moscow, Russian Federation
ITHA	**Ithaca** College	Ithaca, NY, USA
IUPU	**Indiana** Univ., **Purdue** Univ. **Indianapolis**	Indianapolis, IN, USA
JADA	**Jadavpur** Univ.	Calcutta, India
JAGL	**Jagiellonian** Univ.	Kraków, Poland
JHU	**Johns Hopkins** Univ.	Baltimore, MD, USA
JINR	**JINR**, Joint Inst. for Nucl. Research	**Dubna**, Russian Federation
JULI	**Julich**, Forschungszentrum	Julich, Germany
JYV	Univ. of **Jyväskylä**	Jyväskylä, Finland
KAGO	Univ. of **Kagoshima**	Kagoshima-shi, Japan
KANS	Univ. of **Kansas**	Lawrence, KS, USA
KARL	Univ. **Karlsruhe**; (unspecified division) (Historical in *Review*)	Karlsruhe, Germany
KARLE	Univ. **Karlsruhe**; Inst. für Experimentelle Kernphysik	Karlsruhe, Germany
KARLK	Univ. **Karlsruhe**; Inst. für Kernphysik	Karlsruhe, Germany
KARLT	Univ. **Karlsruhe**; Inst. für Theoretische Teilchenphysik	Karlsruhe, Germany
KAZA	**Kazakh** Inst. of High Energy Physics	Alma Ata, Kazakhstan
KEK	**KEK**, National Lab. for High Energy Phys.	Ibaraki-ken, Japan
KENT	Univ. of **Kent**	Canterbury, United Kingdom
KEYN	**Open** Univ.	Milton Keynes, United Kingdom
KFTI	**Kharkiv** Inst. of Physics and Tech. (KFTI)	Kharkiv, Ukraine
KIAE	**Kurchatov**, Inst. of Atomic Energy	**Moscow**, Russian Federation
KIAM	**Keldysh** Inst. of Applied Math., Acad. Sci., Russia	Moscow, Russian Federation
KIDR	**Inst. of Nuclear Sciences**, Vinča (Formerly Boris Kidrič Inst.)	Beograd, Serbia, Yugoslavia
KINK	**Kinki** Univ.	Osaka, Japan
KNTY	Univ. of **Kentucky**	Lexington, KY, USA
KOBE	**Kobe** Univ.	Kobe, Japan
KOMAB	Univ. of **Tokyo, Komaba**	Tokyo, Japan
KONAN	**Konan** Univ.	Kobe, Japan
KOSI	Inst. of Experimental Physics	**Košice**, Slovak Republic
KYOT	**Kyoto** Univ.	Kyoto, Japan
KYOTY	**Kyoto** Univ.; **Yukawa** Inst. for Theor. Physics	Kyoto, Japan
LALO	**LAL**, Laboratoire de l'Accélérateur Linéaire	**Orsay**, France
LANC	Univ. of **Lancaster**	Lancaster, United Kingdom
LANL	**Los Alamos National Lab.** (LANL)	Los Alamos, NM, USA
LAPP	**LAPP**, Lab. d'Annecy-le-Vieux de Phys. des Particules	**Annecy-le-Vieux**, France
LASL	U.C. **Los Alamos Scientific** Lab. (Old name for LANL)	Los Alamos, NM, USA
LAUS	Univ. de **Lausanne**	Lausanne, Switzerland
LAVL	Univ. **Laval**	Quebec, PQ, Canada
LBL	**Lawrence Berkeley Lab.**	Berkeley, CA, USA
LCGT	Univ. di **Torino**	Turin, Italy
LEBD	**Lebedev** Physical Inst.	**Moscow**, Russian Federation
LECE	Univ. di **Lecce**	Lecce, Italy
LEED	Univ. of **Leeds**	Leeds, United Kingdom
LEHI	**Lehigh** Univ.	Bethlehem, PA, USA
LEHM	**Lehman** College of CUNY	Bronx, NY, USA
LEID	Univ. of **Leiden**	Leiden, The Netherlands
LEMO	**Le Moyne** Coll.	Syracuse, NY, USA
LEUV	Katholieke Univ. **Leuven**	Leuven, Belgium
LINZ	Univ. **Linz**	Linz, Austria
LISB	Inst. Nacional de Investigacion Cientifica	**Lisboa** CODEX, Portugal
LISBT	Univ. Técnica de Lisboa, Inst. Superior Técnico	**Lisboa**, Portugal
LIVP	Univ. of **Liverpool**	Liverpool, United Kingdom
LLL	**Lawrence Livermore Lab.** (Old name for LLNL)	Livermore, CA, USA
LLNL	**Lawrence Livermore National Lab.**	Livermore, CA, USA
LOCK	**Lockheed** Palo Alto Res. Lab	Palo Alto, CA, USA

Abbreviations Used in the Full Listings *(Cont'd)*

LOIC	**Imperial** College of Science Tech. & Medicine	London, United Kingdom
LOQM	**Univ. of London**, Queen Mary & Westfield College	London, United Kingdom
LOUC	**University College** London	London, United Kingdom
LOWC	**Westfield** College (Historical, see LOQM (Queen Mary and Westfield joined))	London, United Kingdom
LRL	U.C. Lawrence Radiation Lab. (Old name for LBL)	**Berkeley**, CA, USA
LSU	**Louisiana** State Univ.	Baton Rouge, LA, USA
LUND	Univ. of **Lund**	Lund, Sweden
LVLN	Univ. Catholique de **Louvain**	Louvain-la-Neuve, Belgium
LYON	Institute de Physique Nucléaire de **Lyon** (IPN)	Villeurbanne, France
MADE	Inst. de Estructura de la Materia	**Madrid**, Spain
MADR	**C.I.E.M.A.T**	**Madrid**, Spain
MADU	Univ. Autónoma de **Madrid** C-XI	Madrid, Spain
MANI	Univ. of **Manitoba**	Winnipeg, MB, Canada
MANZ	**Johannes-Gutenberg-Univ.**	**Mainz**, Germany
MARB	Univ. **Marburg**	Marburg, Germany
MARS	Centre de Physique des Particules de **Marseille**	Marseille, France
MASA	Univ. of **Massachusetts**	**Amherst**, MA, USA
MASB	Univ. of **Massachusetts** at Boston	**Boston**, MA, USA
MASD	Univ. of **Massachusetts** Dartmouth	N. **Dartmouth**, MA, USA
MCGI	**McGill** Univ.	Montreal, PQ, Canada
MCHS	Univ. of **Manchester**	Manchester, United Kingdom
MCMS	**McMaster** Univ.	Hamilton, ON, Canada
MEIS	**Meisei** Univ.	Tokyo, Japan
MELB	Univ. of **Melbourne**	Parkville, Victoria, Australia
MEUD	Observatoire de **Meudon**	Meudon, France
MICH	Univ. of **Michigan**	Ann Arbor, MI, USA
MILA	Univ. di **Milano**	Milano, Italy
MINN	Univ. of **Minnesota**	Minneapolis, MN, USA
MISS	Univ. of **Mississippi**	University, MS, USA
MIT	**MIT Massachusetts Inst. of Technology**	Cambridge, MA, USA
MIU	**Maharishi** International Univ.	Fairfield, IA, USA
MIYA	**Miyazaki** Univ.	Miyazaki-shi, Japan
MONP	Univ. de **Montpellier** II	Montpellier, France

[1] CHERNIKOV 92 measures the photon mass at 1.24 K, following a theoretical suggestion that electromagnetic gauge invariance might break down at some low critical temperature. See the erratum for a correction, included here, to the published result.

[2] RYAN 85 measures the photon mass at 1.36 K (see the footnote to CHERNIKOV 92).

[3] See criticism questioning the validity of these results in KROLL 71 and GOLDHABER 71.

graviton

$J = 2$

OMITTED FROM SUMMARY TABLE

graviton MASS

All of the following limits are obtained assuming Yukawa potential in weak field limit. VANDAM 70 argue that a massive field cannot approach general relativity in the zero-mass limit; however, see GOLDHABER 74 and references therein. h_0 is the Hubble constant in units of 100 km s^{-1} Mpc^{-1}.

VALUE (eV)	DOCUMENT ID			COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] DAMOUR	91		Binary pulsar PSR 1913+16
$< 2 \times 10^{-29} h_0^{-1}$	GOLDHABER	74		Rich clusters
$< 7 \times 10^{-28}$	HARE	73		Galaxy
$< 8 \times 10^{4}$	HARE	73		2γ decay

[1] DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity c (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

[1] ALITTI 92B result has two contributions to the systematic error (±0.83); one (±0.81) cancels in m_W/m_Z and one (±0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

[2] ABE 90G result from $W \to e\nu$ is 79.91 ± 0.35 ± 0.24 ± 0.19(scale) GeV and from $W \to \mu\nu$ is 79.90 ± 0.53 ± 0.32 ± 0.08(scale) GeV.

[3] There are two contributions to the systematic error (±0.84): one (±0.81) which cancels in m_W/m_Z and one (±0.21) which is non-cancelling. These were added in quadrature.

[4] ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

[5] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[6] ALBAJAR 89 result is from a total sample of 67 $W \to \mu\nu$ events.

[7] ALBAJAR 89 result is from $W \to \tau\nu$ events.

[8] There are two contributions to the systematic error (±1.4): one (±1.3) which cancels in m_W/m_Z and one (±0.5) which is non-cancelling. These were added in quadrature.

[9] This is enhanced subsample of 172 total events.

[10] Using $W^{\pm} \to \mu^{\pm}\nu$.

W/*Z* MASS RATIO

The fit uses the *W* and *Z* mass, mass difference, and mass ratio measurements.

W WIDTH

The widths labelled "extracted value" are obtained by measuring $R = \sigma(W \to e\nu)/\sigma(Z \to e^+e^-)$ which is equal to $[\sigma(W)/\sigma(Z)]\,[\Gamma(W \to e\nu)/\Gamma(Z \to ee)]\,\Gamma(Z)/\Gamma(W)$. The bracketed quantities can be calculated with plausible reliability. $\Gamma(W)$ is then extracted by using a value of $\Gamma(Z)$ measured at LEP. The Standard Model prediction is 2.067 ± 0.021 (ROSNER 94).

[12] ABE 94B measured $R = 10.90 \pm 0.32 \pm 0.29$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using $m_W = 80.24 \pm 0.10$ GeV, and $m_Z = 91.188 \pm 0.007$ GeV along with the corresponding value of $\sin^2\theta_W = 0.2325 \pm 0.005$. They use $\sigma(W)/\sigma(Z) = 3.33 \pm 0.03$, $\Gamma(Z) = 2.492 \pm 0.007$ GeV, and $\Gamma(W \to e\nu_e)/\Gamma(Z \to e^+e^-) = 2.710 \pm 0.018$.

[13] ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using $m_W = 80.14 \pm 0.27$ GeV, and $m_Z = 91.175 \pm 0.021$ GeV along with the corresponding value of $\sin^2\theta_W = 0.2274$. They use $\sigma(W)/\sigma(Z) = 3.26 \pm 0.07 \pm 0.05$ and $\Gamma(Z) = 2.487 \pm 0.010$ GeV.

[14] ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using $m_W = 80.18 \pm 0.28$ GeV and $m_Z = 91.172 \pm 0.031$ GeV along with $\sin^2\theta_W = 0.2322 \pm 0.0014$. They use $\sigma(W)/\sigma(Z) = 3.23 \pm 0.05$ and $\Gamma(Z) = 2.498 \pm 0.020$ GeV.

[15] ABE 92I report $1216 \pm 38^{+27}_{-31}$ $W \to \mu\nu$ and $106 \pm 10^{+0.2}_{-1}$ $Z \to \mu^+\mu^-$ events which are combined with 2426 $W \to e\nu$ events of ABE 91C to derive the ratio $\sigma_W\,B(W \to \ell\nu)/\sigma_Z\,B(Z \to \ell^+\ell^-) = 10.0 \pm 0.6 \pm 0.4$. Finally the value of $\Gamma(Z)$ measured by LEP 92 is used to extract $\Gamma(W)$.

[16] ABE 90 extract $\Gamma(W) = 2.19 \pm 0.20$ by using the value $\Gamma(Z) = 2.57 \pm 0.07$ GeV. However, in ABE 91C they update their analysis with a new LEP value $\Gamma(Z) = 2.496 \pm 0.016$; the value $\Gamma(W) = 2.12 \pm 0.20$ above reflects this update. They measured $R = 10.2 \pm 0.8 \pm 0.4$, assumed $\sin^2\theta_W = 0.229 \pm 0.007$, and took predicted values $\sigma(W)/\sigma(Z) = 3.23 \pm 0.03$ and $\Gamma(W \to e\nu)/\Gamma(Z \to ee) = 2.70 \pm 0.02$. This yields $\Gamma(W)/\Gamma(Z) = 0.85 \pm 0.08$. The quoted error for $\Gamma(W)$ includes systematic uncertainties. $E^{p\bar{p}}_{cm}$ = 1800 GeV.

[17] ALITTI 90C used the same technique as described for ABE 90. They measured $R = 9.38^{+0.82}_{-0.72} \pm 0.25$, obtained $\Gamma(W)/\Gamma(Z) = 0.902 \pm 0.074 \pm 0.024$. Using $\Gamma(Z) = 2.546 \pm 0.032$ GeV, they obtained the $\Gamma(W)$ value quoted above and the limits $\Gamma(W) < 2.56$ (2.64) GeV at the 90% (95%) CL. $E^{p\bar{p}}_{cm}$ = 546,630 GeV.

[18] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[19] If systematic error is neglected, result is $2.7^{+1.4}_{-1.5}$ GeV. This is enhanced subsample of 172 total events.

W ANOMALOUS MAGNETIC MOMENT (Δκ)

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa = 1$ and $\lambda = 0$. Some papers have defined $\Delta\kappa = 1-\kappa$ and assume that $\lambda = 0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the *W* boson becomes manifest.

	[26] GRAU	85	THEO
	[27] SUZUKI	85	THEO
	[28] HERZOG	84	THEO

[20] ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.2}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\bar{p} \to e\nu\gamma + X$ at $\sqrt{s} = 630$ GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

[21] SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative *W* decay.

[22] SAMUEL 91 use preliminary CDF data for $p\bar{p} \to W\gamma X$ to obtain $-11.3 \le \Delta\kappa \le 10.9$. Note that their $\kappa = 1-\Delta\kappa$.

[23] GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa \lesssim 65\ (M_W^2/\Lambda^2)$.

[24] GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu\bar{\nu}\gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their Δκ has the opposite sign as our definition.

[25] VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33\ (m_W/\Lambda)$. In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine Δκ.

[26] GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

[27] SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa| \lesssim 190\ (m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa| \lesssim 150\ (m_W/\Lambda)^4$ if $|\Delta\kappa| \ll 1$.

[28] HERZOG 84 consider the contribution of *W*-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

W^+ DECAY MODES

W^- modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_j/Γ)		Confidence level
Γ_1	$e^+\nu$		(10.8±0.4) %		
Γ_2	$\mu^+\nu$		(10.6±0.7) %		
Γ_3	$\tau^+\nu$		(10.8±1.0) %		
Γ_4	$\ell^+\nu$	[a]	(10.7±0.5) %		
Γ_5	hadrons		(67.8±1.5) %		
Γ_6	$\pi^+\gamma$		< 5	$\times 10^{-4}$	95%

[a] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 7 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.1$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[29] ABE 94B result is from a measurement of $\sigma B(W \to e\nu)/\sigma B(Z \to e^+e^-)$ = 10.90 ± 0.32 ± 0.29, the theoretical prediction for the cross section ratio, the experimental knowledge of $\Gamma(Z \to e^+e^-)$ = 83.33 ± 0.30 MeV, and $\Gamma(Z)$ = 2.492 ± 0.007.

[30] The first error was obtained by adding the statistical and systematic experimental uncertainties in quadrature. The second error reflects the dependence on theoretical prediction of total W cross section: σ(546 GeV) = $4.7^{+1.4}_{-0.7}$ nb and σ(630 GeV) = $5.8^{+1.8}_{-1.0}$ nb. See ALTARELLI 85B.

[31] ABE 91C result is from a measurement of $\sigma B(W \to e\nu)/\sigma B(Z \to e^+e^-)$, the theoretical prediction for the cross section ratio, and the experimental knowledge of $\Gamma(Z \to e^+e^-)/\Gamma(Z \to$ all).

[32] ALBAJAR 89 experiment determines values of branching ratio times production cross section.

Z

$J = 1$

NOTE ON THE Z BOSON

Precision measurements at the Z-boson resonance using electron-positron colliding beams began in 1989 at the SLC and at LEP. During 1989–93, the four CERN experiments have made high-statistics studies of the Z. The availability of longitudinally polarized electron beams at the SLC in 1993 has enabled a precision determination of the effective electroweak mixing angle $\sin^2\overline{\theta}_W$ that is competitive with the CERN results on this parameter.

The Z-boson properties reported in this section may broadly be categorized as:

- The standard 'lineshape' parameters of the Z consisting of its mass, M_Z, its total width, Γ_Z, and its partial decay widths, Γ(hadrons) and $\Gamma(\ell\bar{\ell})$ where $\ell = e, \mu, \tau, \nu$;
- The b- and c-quark-related partial widths and charge asymmetries which require special techniques;
- Determination of rare Z decay modes and the search for modes that violate known conservation laws.

Details on Z-parameter determination and the study of $Z \to b\bar{b}, c\bar{c}$ at LEP are given in this note.

The standard 'lineshape' parameters of the Z are determined with increasing precision from an analysis of the production cross sections of these final states in e^+e^- collisions at LEP. The $Z \to \nu\bar{\nu}(\gamma)$ state is identified directly by detecting single photon production and indirectly by subtracting the visible partial widths from the total width. Inclusion in this analysis of the forward-backward asymmetry of charged leptons, $A_{FB}^{(0,\ell)}$, of the τ polarization, $P(\tau)$, and its forward-backward asymmetry, $P(\tau)^{fb}$, enables the separate determination of the effective vector ($\overline{g}_V$) and axial vector ($\overline{g}_A$) couplings of the Z to these leptons and the ratio ($\overline{g}_V/\overline{g}_A$) which is related to the effective electroweak mixing angle $\sin^2\overline{\theta}_W$ (see the Standard Model review).

Determination of the b- and c-quark-related partial widths and charge asymmetries involves tagging the b and c quarks. Traditionally this was done by requiring the presence of a prompt lepton in the event with high momentum and high transverse momentum (with respect to the accompanying jet). Precision vertex measurement with silicon detectors enables one to do impact parameter and lifetime tagging. Lately, sophisticated neural-network techniques have been used to classify events as b or non-b on a statistical basis using event-shape variables.

Z-parameter determination at LEP

LEP is run at a few energy points on and around the Z mass constituting an energy 'scan.' The shape of the cross-section variation around the Z peak can be described by a Breit-Wigner *ansatz* with an energy-dependent total width [1]. The **three** main properties of this distribution, viz., the **position** of the peak, the **width** of the distribution, and the **height** of the peak, determine respectively the values of M_Z, Γ_Z, and $\Gamma(e^+e^-) \times \Gamma(f\overline{f})$, where $\Gamma(e^+e^-)$ and $\Gamma(f\overline{f})$ are the electron and fermion partial widths of the Z. The quantitative determination of these parameters is done by writing analytic expressions for these cross sections in terms of the parameters and fitting the calculated cross sections to the measured ones by varying these parameters, taking properly into account all the errors. Single-photon exchange and γ-Z interference are included, and the large (~30 %) initial-state radiation (ISR) effects are taken into account by convoluting the analytic expressions over a 'Radiator Function [1,2]' $H(s,s')$. Thus for the process $e^+e^- \to f\overline{f}$:

$$\sigma_f(s) = \int H(s,s')\ \sigma_f^0(s')\ ds' \tag{1}$$

$$\sigma_f^0(s) = \sigma_Z^0 + \sigma_\gamma^0 + \sigma_{\gamma Z}^0 \tag{2}$$

$$\sigma_Z^0 = \frac{12\pi}{M_Z^2}\ \frac{\Gamma(e^+e^-)\Gamma(f\overline{f})}{\Gamma_Z^2}\ \frac{s\ \Gamma_Z^2}{(s-M_Z^2)^2\ +\ s^2\Gamma_Z^2/M_Z^2} \tag{3}$$

$$\sigma_\gamma^0 = \frac{4\pi\alpha^2(s)}{3s}\ Q_f^2 N_c^f \tag{4}$$

$$\sigma_{\gamma Z}^0 = -\frac{2\sqrt{2}\alpha(s)}{3}\ (Q_f G_F N_c^f g_{Ve} g_{Vf}) \times \frac{(s-M_Z^2)M_Z^2}{(s-M_Z^2)^2 + s^2\Gamma_Z^2/M_Z^2} \tag{5}$$

where Q_f is the charge of the fermion, $N_c^f = 3(1)$ for quark (lepton) and g_{Vf} is the neutral vector coupling of the Z to the fermion-antifermion pair $f\overline{f}$.

Since $\sigma_{\gamma Z}^0$ is expected to be much less than σ_Z^0, the LEP collaborations have generally calculated the interference term in the framework of the Standard Model using the best known values of g_V. This fixing of $\sigma_{\gamma Z}^0$ leads to a tighter constraint on M_Z and consequently a smaller error on its fitted value.

Defining

$$A_f = 2\frac{g_{Vf}\cdot g_{Af}}{(g_{Vf}^2 + g_{Af}^2)} \tag{6}$$

where g_{Af} is the neutral axial-vector coupling of the Z to $f\overline{f}$, the lowest-order expressions for the various lepton-related asymmetries on the Z pole are [3] $A_{FB}^{(0,\ell)} = (3/4)A_eA_f$, $P(\tau) = -A_\tau$, $P(\tau)^{fb} = -(3/4)A_e$, $A_{LR} = A_e$. The full analysis takes into account the energy dependence of the asymmetries. Experimentally A_{LR} is defined as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ where $\sigma_{L(R)}$ are the $e^+e^- \to Z$ production cross sections with left- (right)-handed electrons.

In terms of g_A and g_V, the partial decay width of the Z to $f\overline{f}$ can be written as

$$\Gamma(f\overline{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi}\ (g_{Vf}^2 + g_{Af}^2)\ N_c^f(1+\delta_{\rm QED})(1+\delta_{\rm QCD}) \tag{7}$$

where $\delta_{\rm QED} = 3\alpha Q_f^2/4\pi$ accounts for final-state photonic corrections and $\delta_{\rm QCD} = 0$ for leptons and $\delta_{\rm QCD} = (\alpha_s/\pi) + 1.409(\alpha_s/\pi)^2 - 12.805(\alpha_s/\pi)^3$ for quarks, α_s being the strong coupling constant at $\mu = M_Z$.

In the above framework, the QED radiative corrections have been explicitly taken into account by convoluting over the ISR and allowing the electromagnetic coupling constant to run [4]: $\alpha(s) = \alpha/(1-\Delta\alpha)$. On the other hand, weak radiative corrections that depend upon the assumptions of the electroweak theory and on the values of the unknown $M_{\rm top}$ and $M_{\rm Higgs}$ are accounted for by **absorbing them into the couplings**, which are then called the *effective* couplings $\overline{g}_V$ and $\overline{g}_A$ (or alternatively the effective parameters of the $\star$ scheme of Kennedy and Lynn [5]).

S-matrix approach to the Z

While practically all experimental analyses of LEP/SLC data have followed the 'Breit-Wigner' approach described above, an alternative S-matrix-based analysis is also possible. The Z, like all unstable particles, is associated with a complex pole in the S matrix. The pole position is process independent and gauge invariant. The mass, $\overline{M}_Z$, and width, $\overline{\Gamma}_Z$, can be defined in terms of the pole in the energy plane via [6]

$$\overline{s} = \overline{M}_Z^2 - i\overline{M}_Z\overline{\Gamma}_Z \tag{8}$$

leading to the relations

$$\overline{M}_Z = M_Z/\sqrt{1+\Gamma_Z^2/M_Z^2} \quad (9)$$

$$\approx M_Z - 34 \text{ MeV} \quad (10)$$

$$\overline{\Gamma}_Z = \Gamma_Z/\sqrt{1+\Gamma_Z^2/M_Z^2} \quad (11)$$

$$\approx \Gamma_Z - 0.9 \text{ MeV} \quad (12)$$

Some authors [7] choose to define the Z mass and width via

$$\overline{s} = (\overline{M}_Z - \frac{i}{2}\overline{\Gamma}_Z)^2 \quad (13)$$

which yields $\overline{M}_Z \approx M_Z - 26$ MeV, $\overline{\Gamma}_Z \approx \Gamma_Z - 1.2$ MeV.

The L3 collaboration at LEP (ADRIANI 93H, ADRIANI 93M) have analyzed their data using the S-matrix approach as defined in Eq. (8), in addition to the conventional one. As expected, they observe a downward shift of ≈ 34 MeV in the Z mass.

Handling the large-angle e^+e^- final state

Unlike other $f\bar{f}$ decay final states of the Z, the e^+e^- final state has a contribution not only from the s-channel but also from the t-channel and s-t interference. The full amplitude is not amenable to fast calculation, which is essential if one has to carry out minimization fits within reasonable computer time. The usual procedure is to calculate the non-s channel part of the cross section separately using the Standard Model program ALIBABA [8] using the 'most reasonable' values of $M_{\rm top}$, and $M_{\rm Higgs}$ and add it to the s-channel cross section calculated as for other channels. This leads to two additional sources of error in the analysis: firstly, the theoretical calculation in ALIBABA itself is known to be accurate to ~ 0.5 %, and secondly, there is uncertainty due to unknown $M_{\rm top}$ and $M_{\rm Higgs}$. These additional errors are propagated into the analysis by including them in the systematic error on the e^+e^- final state.

Errors due to uncertainty in LEP energy determination [9]

The systematic errors related to the LEP energy measurement can be classified as:

- The absolute energy scale error;
- Energy-point-to-energy-point errors due to the non-linear response of the magnets to the exciting currents;
- Energy-point-to-energy-point errors due to possible higher-order effects in the relationship between the dipole field and beam energy;
- Energy reproducibility errors due to various unknown uncertainties in temperatures, tidal effects, corrector settings, RF status *etc.* Since one groups together data taken at 'nominally same' energies in different fills, it can be assumed that these errors are uncorrelated and are reduced by $\sqrt{\overline{N}_{\rm fill}}$ where $\overline{N}_{\rm fill}$ is the (luminosity weighted) effective number of fills at a particular energy point.

At each energy point the last two errors can be summed into one point-to-point error.

Choice of fit parameters

The LEP collaborations have chosen the following primary set of parameters for fitting: M_Z, Γ_Z, $\sigma^0_{\rm hadron}$, R(lepton), $A_{FB}^{(0,\ell)}$, where R(lepton) = Γ(hadrons)/Γ(lepton), $\sigma^0_{\rm hadron} = 12\pi\Gamma(e^+e^-)\Gamma(\text{hadrons})/M_Z^2\Gamma_Z^2$. With a knowledge of these fitted parameters and their covariance matrix, any other parameter can be derived. The main advantage of these parameters is that they form the **least correlated** set of parameters, so that it becomes easy to combine results from the different LEP experiments.

Thus, the most general fit carried out to cross section and asymmetry data determines the **nine parameters**: M_Z, Γ_Z, $\sigma^0_{\rm hadron}$, $R(e)$, $R(\mu)$, $R(\tau)$, $A_{FB}^{(0,e)}$, $A_{FB}^{(0,\mu)}$, $A_{FB}^{(0,\tau)}$. Assumption of lepton universality leads to a **five-parameter fit** determining M_Z, Γ_Z, $\sigma^0_{\rm hadron}$, R(lepton), $A_{FB}^{(0,\ell)}$. The use of **only** cross-section data leads to six- or four-parameter fits if lepton universality is or is not assumed, *i.e.*, $A_{FB}^{(0,\ell)}$ values are not determined.

In order to determine the best values of the effective vector and axial vector couplings of the charged leptons to the Z, the above mentioned nine- and five-parameter fits are carried out with added constraints from the measured values of A_τ and A_e obtained from τ polarization studies at LEP and the determination of A_{LR} at SLC.

Combining results from the four LEP experiments [10]

Each LEP experiment provides the values of the parameters mentioned above together with the full covariance matrix. The statistical and experimental systematic errors are assumed to be uncorrelated among the four experiments. The sources of **common** systematic errors are i) the LEP energy uncertainties, and ii) the effect of theoretical uncertainty in calculating the small-angle Bhabha cross section for luminosity determination and in estimating the non-s channel contribution to the large-angle Bhabha cross section. Using this information, a full covariance matrix, V, of all the input parameters is constructed and a combined parameter set is obtained by minimizing $\chi^2 = \Delta^T V^{-1}\Delta$, where Δ is the vector of residuals of the combined parameter set to the results of individual experiments.

Study of $Z \to b\bar{b}, c\bar{c}$ at LEP

These studies lead to the experimental determination of the ratios of the partial widths $\Gamma(b\bar{b})/\Gamma(\text{hadrons})$, $\Gamma(c\bar{c})/\Gamma(\text{hadrons})$, and the forward-backward (charge) asymmetries $A_{FB}^{(0,b)}$ and $A_{FB}^{(0,c)}$. Each LEP experiment has used more than one technique of b,c tagging, and then used certain assumptions, some model dependent, to extract the final numbers. This makes the task of **combining** these LEP results quite daunting. A first step in this direction was made recently [10] for a joint LEP presentation for the 1993 summer conferences. In principle, the task is the same as for combining results on the lineshape: identification of the **common systematic errors**, which in this case exist not only among different LEP experiments, but

also within one collaboration if different (partially correlated) methods are employed to extract the same quantity.

Extraction of $\Gamma(b\bar{b})/\Gamma$(hadrons)

Three methods have been used to tag a b quark: lepton tagging, analysis of event shape, and lifetime tagging. The latter includes impact-parameter or decay-length double tags, or in combination with the lepton or event-shape tags. The various sources of common systematic errors are:

- Semileptonic decay model;
- Semileptonic branching ratios of b and c quarks;
- $c\bar{c}$ contamination, $\Gamma(c\bar{c})/\Gamma$(hadrons);
- Variation of Monte Carlo parameters, in particular the b-fragmentation function;
- Hemisphere correlations.

Some other possible common errors due to charmed hadron composition, b,c production in uds events, *etc.* are expected to be small.

Extraction of $\Gamma(c\bar{c})/\Gamma$(hadrons)

In addition to the methods of lepton tagging, event-shape analysis, and lifetime tags, $D^*(2010)$ tagging is also used to identify c quarks. The common systematic errors are basically the same as for the b-tagging case, where instead of $c\bar{c}$ contamination, it is $b\bar{b}$ contamination.

Extraction of $A_{FB}^{(0,b)}$ and $A_{FB}^{(0,c)}$

For determining the asymmetry, it is essential to identify the charge of the quark in addition to tagging an event as due to $b\bar{b}$ or $c\bar{c}$. Thus, asymmetry measurements have utilized a lepton tag and a lifetime tag in combination with a jet-charge measurement and a $D^*(2010)$ tag. The values of $A_{FB}^{(0,b)}$ are corrected for the effect of $B^0\overline{B^0}$ mixing. The common errors in $A_{FB}^{(0,b)}$ are due to:

- Semileptonic decay model and branching ratios;
- Fragmentation;
- $\Gamma(b\bar{b})$ and $\Gamma(c\bar{c})$;
- $B^0\overline{B^0}$ mixing;
- $A_{FB}^{(0,c)}$.

For $A_{FB}^{(0,c)}$ the first four common errors are the same as for $A_{FB}^{(0,b)}$. The fifth error is due to $A_{FB}^{(0,b)}$; the sixth is due to the uncertainty in the probability of producing a $D^*(2010)$ in $c\bar{c}$ and $b\bar{b}$ events and in the $D^*(2010)$ branching ratio.

Z MASS

The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. We believe that this set is the most free of correlations. Common systematic errors are taken into account. For more details, see the the 'Note on the Z Boson.'

The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. The value is 34 MeV greater than the real part of the position of the pole (in the energy plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma - Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ADRIANI 93H for a detailed investigation of both these issues.

[16] The second error of 4.5 MeV is due to a common LEP energy uncertainty.
[17] ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.
[18] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.
[19] Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W) = 2.65$ GeV then gives $\Gamma(Z) < 2.89 \pm 0.19$ or $= 2.17^{+0.50}_{-0.37} \pm 0.16$.
[20] The systematic error is from the uncertainty in the LEP energy calibration.
[21] The error in ADRIANI 93F includes 4 MeV due to the uncertainty in LEP energy calibration.
[22] ADRIANI 93H use the S-matrix approach to determine the pole position for the Z boson.
[23] The error in BUSKULIC 93J includes 4 MeV due to the uncertainty in LEP energy calibration.
[24] QUAST 93 is a combined analysis of LEP results as of Feb. 1993. A common systematic error of 4 MeV is taken into account.
[25] BANERJEE 92 is a combined analysis of the four LEP experiments as of March 1991.
[26] The systematic error (0.005) is an error in common to the 4 LEP experiments.
[27] LEP 92 is combined analysis by the four LEP experiments as of December 1991. Systematic errors are included.

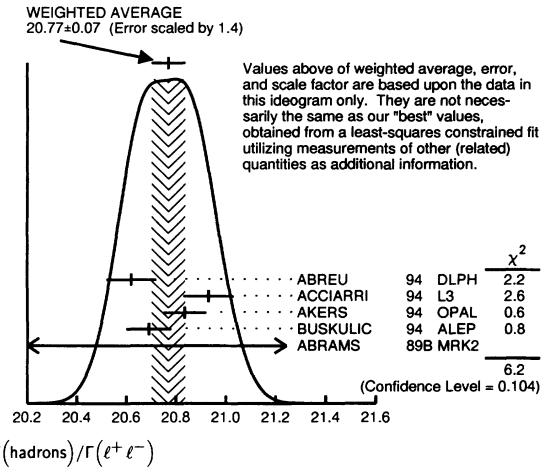
[61] ABRAMS 89D have included both statistical and systematic uncertainties in their quoted errors.
[62] QUAST 93 is a combined analysis of LEP results as of Feb. 1993.
[63] LEP 92 is combined analysis by the four LEP experiments as of December 1991. Systematic errors are included.
[64] ABREU 91F report $\Gamma(\tau\tau) = 82.7 \pm 2.1 \pm 1.1$ MeV and provided us with this branching ratio from the same data and analysis.
[65] ADEVA 91E report $B(\tau\tau) = 3.36 \pm 0.11\%$ and $\Gamma(\tau\tau) = 84.0 \pm 2.7$ MeV and provided us with this branching ratio from the same data and analysis.
[66] ALEXANDER 91F report $\Gamma(\tau\tau) = 82.7 \pm 1.9$ MeV and provided us with this branching ratio from the same data and analysis.



Γ(hadrons)/Γ(ℓ⁺ℓ⁻) — Γ6/Γ4

ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

Our fit result is obtained requiring lepton universality.

0.223±0.032±0.059		[84] AKRAWY	91E	OPAL	E_{cm}^{ee} = 88–95 GeV

[79] ABREU 93I assume that the D_s and charmed baryons are equally produced at LEP and CLEO (10 GeV) energies.
[80] ABREU 92O use the neural network techinque to tag heavy flavour events among a sample of 123k selected hadronic events. The systematic error consists of three parts: due to Monte Carlo (MC) parametrization (0.023), choice of MC model (0.033) and detector effects (0.009) added in quadrature.
[81] ALEXANDER 91B (OPAL) obtains the result from an analysis of the $D^{*\pm}$ momentum distribution (c production is tagged via $D^{*\pm}$ production). ALEXANDER 91B include all errors due to their experiment in the first quoted error and all others in the second (±0.020).
[82] ABREU 90H use CLEO probability for $c\overline{c} \to D^*(2010)^{\pm}$ X with $D^*(2010)^{\pm} \to D^0\pi^{\pm}$. Systematic error includes ±0.026 due to uncertainties in branching ratios.
[83] DECAMP 90L find $B(c \to e)\Gamma(c\overline{c})/\Gamma(\text{hadrons}) = 0.0133 \pm 0.0040^{+0.0038}_{-0.0031}$. Assumes $B(c \to e) = 0.090 \pm 0.013$. Systematic error includes about ±0.025 due to uncertainties in branching ratios.
[84] AKRAWY 91E (OPAL) performs a fit to the p and p_T spectra of muon candidates, used to tag heavy flavor semileptonic decays. AKRAWY 91E systematic error includes the uncertainty from semileptonic branching ratios (±0.025) plus other systematics (±0.053).

$\Gamma(b\overline{b})/\Gamma(\text{hadrons})$ Γ_{10}/Γ_6

Following the procedure of the joint LEP effort to extract $\Gamma(b\overline{b})/\Gamma$(hadrons) (see the 'Note on the Z Boson'), we have divided the measurements into 3 classes, based on lepton tagging, event shapes, and lifetime tagging. For each group, the systematic errors are split into those specific to an experiment (uncorrelated systematics) and those in common between the results (common systematics). For the overall average, the results from the three tagging techniques are assumed to be entirely uncorrelated.

[85] AKERS 94D perform an analysis based on a "mixed tag" method (impact parameter and lepton tagging). The systematic error includes a contribution (±0.007) due to the $\Gamma(c\overline{c})/\Gamma$(hadrons) uncertainty.
[86] ACTON 93I use both electrons and muons to tag B semileptonic decays. The systematic error includes components due to b and c quark fragmentation uncertainties, decay branching ratios, and $\Gamma(c\overline{c})/\Gamma$(hadrons).
[87] ACTON 93M tagged $Z \to b\overline{b}$ events using the impact parameter technique.
[88] ADRIANI 93E use a multidimensional analysis based on a neural network approach.
[89] BUSKULIC 93M use a method which tags the $Z \to b\overline{b}$ decays through the lifetime of the produced heavy hadrons. The systematic error includes a contribution of ±0.0016 due to the uncertainty of the charm partial width (for compatibility, we quote the result obtained with the Standard Model prediction $\Gamma(c\overline{c})/\Gamma$(hadrons) = 0.171).
[90] BUSKULIC 93N use event shape and high p_T lepton discriminators applied to both hemispheres.
[91] ABREU 92O use the neural network technique to tag heavy flavour events among a sample of 123k selected hadronic events. The systematic error consists of three parts: due to Monte Carlo (MC) parametrization (0.010), choice of MC model (0.008), and detector effects (0.011) added in quadrature.
[92] ADEVA 91C report $\Gamma(b\overline{b}) = 385 \pm 7 \pm 11 \pm 19$ MeV; we use their Γ(hadrons) = 1742 ± 19 MeV to obtain the branching ratio. The systematic error includes the semileptonic branching ratio uncertainty (±0.011) plus other systematics (±0.006).
[93] JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of ≥ 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (±0.014).
[94] DECAMP 90L find $B(b \to e)\Gamma(b\overline{b})/\Gamma(\text{hadrons}) = 0.0219 \pm 0.0017 \pm 0.0010$. They assume $B(b \to e) = 0.102 \pm 0.007 \pm 0.007$. The quoted systematic error is dominated by that from the semileptonic branching ratio.
[95] KRAL 90 used isolated leptons and found $\Gamma(b\overline{b})/\Gamma(\text{total}) = 0.17\ ^{+0.07}_{-0.06} \pm 0.04 - 0.03$.
[96] AKERS 93B use a simultaneous fit to single and dilepton events (electrons and muons) to tag $Z \to b\overline{b}$.
[97] ABREU 92 result is from an indirect technique. They measure the lifetime τ_B, but use a world average of τ_B independent of $\Gamma(b\overline{b})$ and compare to their $\Gamma(b\overline{b})$ dependent lifetime from a hadron sample.
[98] ABREU 92K use boosted–sphericity technique to tag and enrich the $b\overline{b}$ content with a sample of 50k hadronic events. Most of the systematic error is from hadronization uncertainty.
[99] ACTON 92I use high p (> 4 GeV), high p_T (> 0.8 GeV) electrons to tag $Z \to b\overline{b}$ events.
[100] For AKRAWY 91E, the systematic error includes the uncertainty from semileptonic branching ratios (±0.021) plus other systematics (±0.011).
[101] ADEVA 90E used isolated muons and found $B(B \to \mu)\Gamma(b\overline{b}) = 41.7 \pm 2.9 \pm 3.0$ MeV. The systematic error of ±0.024 above includes 0.02 due to uncertainty in $B(B \to \mu)$ added in quadrature to ±0.014 systematic.

Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e and A_τ, or ν_e scattering. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e and A_τ measurements. See "Note on the Z boson" for details.

Within the current data set, the reason for the smallness of g_V^μ compared to g_V^e and g_V^τ is due to the large value of A_e which is heavily weighted by the SLD result. This large value of A_e leads to a large value of g_V^e. Since g_V^μ is obtained using the relation $A_{FB}^\mu = 0.75 \times A_e \times A_\mu$, a large value of g_V^e leads to a SMALL value of g_V^μ. Concerning the τ, its g_V gets mainly determined directly from A_τ which is obtained from a measurement of the τ polarization (see "Note on the Z boson").

[151] Using forward-backward lepton asymmetries.
[152] The τ polarization result has been included.
[153] QUAST 93 is a combined analysis of LEP results as of Feb. 1993. QUAST 93 use also the average LEP values for τ polarization and the forward–backward τ polarisation asymmetry. Assumes lepton universality.
[154] BANERJEE 92 is a combined analysis of the four LEP experiments as of March 1991. Forward-backward lepton asymmetries are used.
[155] LEP 92 is a combined analysis of the four LEP experiments as of December 1991. Forward-backward lepton asymmetries are used.

Z AXIAL-VECTOR COUPLINGS

These quantities are the effective axial-vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e and A_τ, or ν_e scattering. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e and A_τ measurements. See "Note on the Z boson" for details.

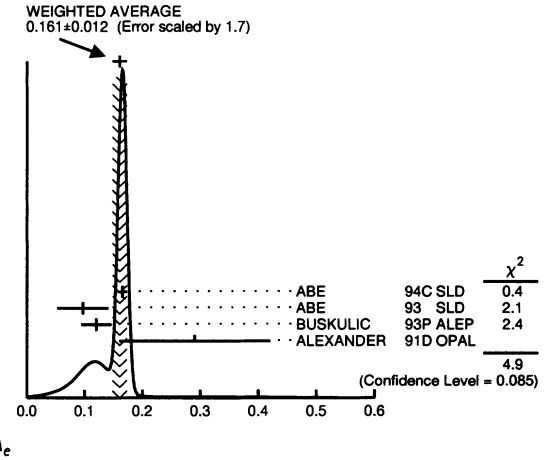
Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$



where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the 'Note on the Z Boson.'

A_e

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

[173] ACTON 93K use the lepton tagging technique. The systematic error includes the uncertainty on the mixing parameter.

[174] AKERS 93D identify the b and c decays using D^*.

[175] B tagging via its semimuonic decay. Experimental value corrected using average LEP B^0-$\overline{B}^0$ mixing parameter $\chi = 0.143 \pm 0.023$.

[176] ADRIANI 92D use both electron and muon semileptonic decays. The quoted systematic error is common to all measurements.

[177] DECAMP 91E use the lepton-tagging technique.

[178] QUAST 93 is a combined analysis of LEP results as of Feb. 1993.

[179] ADRIANI 92D use both electron and muon semileptonic decays. For this measurement ADRIANI 92D average over all $\sqrt{s}$ values to obtain a single result.

CHARGE ASYMMETRY IN $e^+e^- \to q\overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B^0-$\overline{B}^0$ mixing and on other electroweak parameters.

[180] QUAST 93 is a combined analysis of LEP results as of Feb. 1993.

[181] ABREU 92I has 0.14 systematic error due to uncertainty of quark fragmentation.

[182] ACTON 92L use the weight function method on 259k selected $Z \to$ hadrons events. The systematic error includes a contribution of 0.2 due to B^0-$\overline{B}^0$ mixing effect, 0.4 due to Monte Carlo (MC) fragmentation uncertainties and 0.3 due to MC statistics. ACTON 92L derive a value of $\sin^2\theta_W^{\rm eff}$ to be 0.2321 ± 0.0017 ± 0.0028.

Searches for Higgs Bosons — H^0 and $H^\pm$

NOTE ON THE HIGGS BOSON

(by I. Hinchliffe, LBL)

The Standard Model [1] contains one neutral scalar Higgs boson, which is a remnant of the mechanism that breaks the SU(2) × U(1) symmetry and generates the W and Z boson masses. The Higgs couples to quarks and leptons of mass m_f with a strength $gm_f/2M_W$. Its coupling to W and Z bosons is of strength g, where g is the coupling constant of the SU(2) gauge theory. Consequently its coupling to stable matter is very small, and its production and detection in experiments is difficult. An exception is its production in the decay of the Z boson. Since large numbers of Z's can be produced and the coupling of the Z to the Higgs is unsuppressed, experiments

at LEP are now able to rule out a significant range of Higgs masses.

If the Higgs mass is very large, the couplings of the Higgs to itself and to longitudinally polarized gauge bosons become large. Requiring that these couplings remain weak enough so that perturbation theory is applicable implies that $M_H \lesssim 1$ TeV [2]. While this is not an absolute bound, it is an indication of the mass scale at which one can no longer speak of an elementary Higgs boson. This fact is made more clear if one notes that the width of the Higgs boson is proportional to the cube of its mass and that a boson of mass 1 TeV has a width of 500 GeV.

It is believed that scalar field theories of the type used to describe Higgs self-interactions can only be effective theories valid over a limited range of energies if the Higgs self-coupling and hence Higgs mass is nonzero. A theory of this type that is valid at all energy scales must have zero coupling. The range of energies over which the interacting theory is valid is a function of the Higgs self-coupling and hence its mass. An upper bound on the Higgs mass can then be determined by requiring that the theory be valid (*i.e.*, have a nonzero value of the renormalized Higgs self-coupling) at all scales up to the Higgs mass [3]. Non-perturbative calculations using lattice [4] gauge theory that can be used to compute at arbitrary values of the Higgs mass indicate that $M_H \lesssim 750$ GeV.

If the Higgs mass were small, then the vacuum (ground) state with the correct value of M_W would cease to be the true ground state of the theory [5]. A theoretical constraint can then be obtained from the requirement that this is not the case, *i.e.*, that the our universe is in the true minimum of the Higgs potential. The constraint can be parametrized approximately as [6]

$$M_H > 1.85\,(m_{\rm top} - 85\ {\rm GeV})\ .$$

This constraint may be too restrictive. Strictly speaking we can only require that the predicted lifetime of our universe, if it is not at the true minimum of the Higgs potential, be longer than its observed age. This constraint can be approximated by [7,8]

$$M_H > 5.9\,(m_{\rm top} - 170\ {\rm GeV})\ .$$

Experiments at LEP are able to exclude a large range of Higgs masses. They search for the decay $Z \to HZ^*$. Here Z^* refers to a virtual Z boson that can appear in the detector as e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $\nu\overline{\nu}$ (*i.e.*, missing energy) or hadrons. The experimental searches have considered both $H \to$ hadrons and $H \to \tau^+\tau^-$. The best limits are shown in the listings below.

Precision measurement of electroweak parameters such as M_W and the various asymmetries at LEP and SLC are becoming sensitive enough that they can in principle constrain the Higgs mass through its effect in radiative corrections. Currently, the precision tests allow the entire range from the direct LEP limit ($M_H \gtrsim 60$ GeV) to 1 TeV [9]. However, a measurement of the top mass might enable a constraint on M_H to be extracted.

Extensions of the standard model, such as those based on supersymmetry [10], can have more complicated spectra of Higgs bosons. The simplest extension has two Higgs doublets whose neutral components have vacuum expectation values v_1 and v_2, both of which contribute to the W and Z masses. The physical particle spectrum contains one charged Higgs boson ($H^\pm$), two neutral scalars (H_1^0, H_2^0), and one pseudoscalar (A^0) if CP is conserved in the scalar sector [11]. In the simplest version of the supersymmetric model, there is an upper bound on the mass of one of these scalars. The bound depends upon the top quark mass; for $m_t = 150$ GeV, the bound is $M_{H_1^0} \lesssim 110$ GeV [12]. In models where all fermions of the same electric charge receive their masses from only one of the two doublets (v_2 gives mass to the charge 2/3 quarks, while v_1 gives mass to the charged leptons and the charge 1/3 quarks), there are, as in the standard model, no flavor-changing neutral currents at lowest order in perturbation theory. The H_i^0 and A^0 couplings to fermions depend on v_2/v_1 and are either enhanced or suppressed relative to the couplings in the standard model. Experiments at LEP are able to exclude ranges of masses for neutral Higgs particles in these models. These ranges depend on the values of v_2/v_1. See the listings below on H_1^0, Mass Limits in Supersymmetric Models.

Searches for charged Higgs bosons depend on the assumed branching fractions to $\nu\tau$, $c\overline{s}$, and $c\overline{b}$. See the listings for $H^\pm$ Mass Limit.

H^0 (Higgs Boson) MASS LIMITS

These limits apply to the Higgs boson of the three-generation Standard Model with the minimal Higgs sector. Limits that depend on the $Ht\bar{t}$ coupling may also apply to a Higgs boson of an extended Higgs sector whose couplings to up-type quarks are comparable to or larger than those of the standard one-doublet model H^0 couplings.

For comprehensive reviews, see Gunion, Haber, Kane, and Dawson, "The Higgs Hunter's Guide," (Addison-Wesley, Menlo Park, CA, 1990) and R.N. Cahn, Reports on Progress in Physics **52** 389 (1989). For a review of theoretical bounds on the Higgs mass, see M. Sher, Physics Reports (Physics Letters C) **179** 273 (1989).

[1] ABREU 94G searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \tau^+\tau^-, \nu\bar{\nu})$ with $H^0 \to q\bar{q}$. Four $\ell^+\ell^-$ candidates were found (all yielding low mass) consistent with expected backgrounds.

[2] AKERS 94B searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \nu\bar{\nu})$ with $H^0 \to q\bar{q}$. One $\nu\bar{\nu}$ and one $\mu^+\mu^-$ candidate were found consistent with expected backgrounds.

[3] ADRIANI 93C searched for $Z \to H^0 + (\nu\bar{\nu}, e^+e^-, \mu^+\mu^-)$ with H^0 decaying hadronically or to $\tau^+\tau^-$. Two e^+e^- and one $\mu^+\mu^-$ candidates are found consistent with expected background.

[4] BUSKULIC 93H searched for $Z \to H^0\nu\bar{\nu}$ (acoplanar jets) and $Z \to H^0 + (e^+e^-, \mu^+\mu^-)$ (lepton pairs in hadronic events).

[5] GROSS 93 combine data taken by four LEP experiments through 1991.

[6] ABREU 92D give $\sigma(e^+e^- \to Z \to H^0\gamma)\cdot B(H^0 \to$ hadrons) <8 pb (95% CL) for m_{H^0} <75 GeV and E_γ >8 GeV.

[7] ABREU 92J searched for $Z \to H^0 + (ee, \mu\mu, \tau\tau, \nu\bar{\nu})$ with $H^0 \to q\bar{q}$. Only one candidate was found, in the channel ee + 2jets, with a dijet mass 35.4 ± 5 GeV/c^2, consistent with the expected background of 1.0 ± 0.2 events in the 3 channels e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, and of 2.8 ± 1.3 events in all 4 channels. This paper excludes 12–38 GeV. The range 0–12 GeV is eliminated by combining with the analyses of ABREU 90C and ABREU 91B.

[8] ADEVA 92B searched for $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu, \tau\tau)$ with $H^0 \to$ anything, $Z \to H^0 + \tau\tau$ with $H^0 \to q\bar{q}$, and $Z \to H^0 + q\bar{q}$ with $H^0 \to \tau\tau$. The analysis excludes the range $30 < m_{H^0} < 52$ GeV.

[9] ADRIANI 92F give $\sigma(e^+e^- \to Z \to H^0\gamma)\cdot B(H^0 \to$ hadrons) <(2–10) pb (95% CL) for m_{χ^0} = 25–85 GeV. Using $\sigma(e^+e^- \to Z) = 30$ nb, we obtain $B(Z \to H^0\gamma)B(H^0 \to$ hadrons) <(0.7–3) × 10^{-4} (95% CL).

[10] DECAMP 92 searched for most possible final states for $Z \to H^0 Z^*$.

[11] ABREU 91B searched for $Z \to H^0 + \ell\bar{\ell}$ with missing H^0 and $Z \to H^0 + (\nu\bar{\nu}, \ell\bar{\ell}, q\bar{q})$ with $H^0 \to ee$.

[12] ACTON 91 searched for $e^+e^- \to Z^* H^0$ where $Z^* \to e^+e^-, \mu^+\mu^-$, or $\nu\bar{\nu}$ and $H^0 \to$ anything. Without assuming the minimal Standard Model mass-lifetime relationship, the limit is $m_{H^0} > 9.5$ GeV.

[13] ADEVA 91 searched for $Z \to H^0 + (\mu\mu, ee, \nu\bar{\nu})$. This paper only excludes $15 < m_{H^0} < 41.8$ GeV. The 0–15 GeV range is excluded by combining with the analyses of previous L3 papers.

[14] ADEVA 91D obtain a limit $B(Z \to H^0\gamma)\cdot B(H^0 \to$ hadrons) < 4.7 × 10^{-4} (95%CL) for m_{H^0} = 30–86 GeV. The limit is not sensitive enough to exclude a standard H^0.

[15] AKRAWY 91 searched for the channels $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu, \tau\tau)$ with $H^0 \to q\bar{q}$, $\tau\tau$, and $Z \to H^0 q\bar{q}$ with $H^0 \to \tau\tau$.

[16] AKRAWY 91C searched the decay channels $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu)$ with $H^0 \to q\bar{q}$.

[17] ABE 90E looked for associated production of H^0 with $W^\pm$ or Z in $p\bar{p}$ collisions at $\sqrt{s}$ = 1.8 TeV. Searched for H^0 decays into $\mu^+\mu^-$, $\pi^+\pi^-$, and K^+K^-. Most of the excluded region is also excluded at 95% CL.

[18] ABREU 90C searched for the channels $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu)$ and $H^0 + q\bar{q}$ for m_H < 1 GeV.

[19] ADEVA 90H searched for $Z \to H^0 + (\mu\mu, ee, \nu\bar{\nu})$.

[20] ADEVA 90N looked for $Z \to H^0 + (ee, \mu\mu)$ with missing H^0 and with $H^0 \to ee$, $\mu\mu$, $\pi^+\pi^-$, K^+K^-.

[21] AKRAWY 90C based on 825 nb^{-1}. The decay $Z \to H^0\nu\bar{\nu}$ with $H^0 \to \tau\bar{\tau}$ or $q\bar{q}$ provides the most powerful search means, but the quoted results sum all channels.

[22] AKRAWY 90P looked for $Z \to H^0 + (ee, \mu\mu)$ (H^0 missing) and $Z \to H^0\nu\bar{\nu}$, $H^0 \to e^+e^-, \gamma\gamma$.

[23] DECAMP 90 limits based on 11,550 Z events. They searched for $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu, \tau\tau, q\bar{q})$. The decay $Z \to H^0\nu\bar{\nu}$ provides the most powerful search means, but the quoted results sum all channels. Different analysis methods are used for $m_{H^0} < 2m_\mu$ where Higgs would be long-lived. The 99% confidence limits exclude m_{H^0} = 0.040–12 GeV.

[24] DECAMP 90H limits based on 25,000 $Z \to$ hadron events.

[25] DECAMP 90M looked for $Z \to H^0\ell\ell$, where H^0 decays outside the detector.

[26] DECAMP 90N searched for the channels $Z \to H^0 + (\nu\bar{\nu}, ee, \mu\mu, \tau\tau)$ with $H^0 \to$ (hadrons, $\tau\tau$).

Limits from Other Techniques

H^0 Indirect Mass Limits from Electroweak Analysis

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$35\ ^{+205}_{-\ 26}$		[27] ELLIS	94	RVUE	
$73\ ^{+178}_{-\ 13}$		[28] BLONDEL	93	RVUE

> 1.4	68	[32] ELLIS	92	RVUE	Electroweak
$25\ ^{+275}_{-\ 19}$		[33] ELLIS	92E	RVUE	
$50\ ^{+353}_{-\ \ 0}$		[34] RENTON	92	RVUE	
		[35] SCHAILE	92	RVUE	

[27] ELLIS 94 fit to LEP, SLD, W-mass, and neutrino data available in the summer of 1993. The fit to m_H, m_t, and α_s yields $m_t = 140^{+21}_{-22}$ GeV and $\alpha_s(m_Z) = 0.116^{+0.007}_{-0.006}$.

[28] BLONDEL 93 perform two dimensional ($m_t - m_H$) fit to LEP electroweak data available in the spring of 1993. α_s = 0.117 ± 0.005 is used and m_t >108 GeV, m_H > 62.5 GeV imposed. m_{H^0} = 1 TeV is compatible with the data within two standard deviations.

[29] ELLIS 93B fit to LEP and neutrino data available in the summer of 1993. m_t is adjusted to minimize χ^2 and $\alpha_s(m_Z)$ = 0.123 ± 0.006 is used. 95% CL limit for m_H <250 GeV is claimed.

[30] NOVIKOV 93B use a subset of the most accurate and "gluon-free" data available in the spring of 1993. They use m_W, $\Gamma(\ell\ell)$, and $A_{FB}^{\ell\ell}$.

[31] DELAGUILA 92B perform two dimensional ($m_t - m_H$) fit to various LEP, neutrino, eH, and $p\bar{p}$ data available through 1991 with direct limits on m_t, m_H. The result $m_H = 65^{+245}_{-\ 4}$ is not expected from the statistical sensitivity of the data but due to deviation of the data from the Standard Model expectation.

[32] ELLIS 92 result is from a fit to electroweak data from LEP and elsewhere. They also find m_H <160 GeV at 68%CL and 0.5 <m_H <1500 GeV at 90%CL with m_t unconstrained.

[33] ELLIS 92E perform fit to electroweak data available in the spring of 1992. m_t is adjusted to minimize χ^2 and $\alpha_s(m_Z)$ = 0.118 ± 0.008 is used.

[34] RENTON 92 use electroweak data available in 1991 and require m_H >50 GeV. The constraint α_s = 0.114 ± 0.007 was used.

Gauge & Higgs Boson Full Listings

Higgs Bosons — H^0 and $H^\pm$

[35] SCHAILE 92 performs fit to LEP electroweak data (as of summer 1991) as well as m_W (UA2/CDF) and νN (CDHS/CHARM). The fit with the constraint $m_H > 50$ GeV gives $m_H = 50^{+192}_{-0}$ GeV. However, the m_H dependence of the χ^2 is not consistent from that expected from the present statistics and the sensitivity to m_H arises from the fact that the measured values of g_A and A^b_{FB} deviate from the Standard Model expectation. Therefore, the result is not considered to be significant.

From Quarkonium Decay

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>0.086	90	[36] ANTREASYAN	90C	CBAL	$\Upsilon(1S) \to H^0\gamma$
none 0.29–0.57	90	[37] ALBRECHT	89	ARG	$\Upsilon(1S) \to H^0\gamma$, $(H^0 \to \pi^+\pi^-)$
none 0.21–5	90	[38] LEE-FRANZINI	88	CUSB	$\Upsilon(1S,3S) \to \gamma H^0$
		[39] DRUZHININ	87	ND	$\phi \to \gamma H^0$, $(H^0 \to \pi^0\pi^0)$

[36] ANTREASYAN 90C obtain $B(\Upsilon(1S) \to H^0\gamma) < 3.5\times10^{-5}$ at 90% CL for $m_{H^0} < 2m_e$ and similar limits for heavier Higgs masses. The listed limit assumes the QCD/relativistic reduction factor for the width of 0.5. The limit is reduced to 39 MeV if 0.25 is used instead.

[37] ALBRECHT 89 give a limit $B(\Upsilon(1S) \to H^0\gamma)\cdot B(H^0 \to \pi^+\pi^-) < 3\text{–}4.5 \times 10^{-5}$ for $m_{H^0} = 290\text{–}570$ MeV, which is lower than the predition including first order QCD corrections and assuming $B(H^0 \to \pi^+\pi^-) > 45\%$.

[38] LEE-FRANZINI 88 presents updated results from the CUSB experiment (see FRANZINI 87 for more details). First order QCD correction included with $\alpha_s \simeq 0.2$ ($\Lambda = 0.2$ GeV and $n(f) = 4$). The order α_s correction reduced the rate for $\Upsilon(1S) \to H^0\gamma$ by a factor of 2 (yielding these limits). The impact of order α_s^2 and of relativistic corrections are unknown. If they amounted to another factor of 2 suppression, the above limit would be essentially eliminated.

[39] DRUZHININ 87 sets limit $B(\phi \to \gamma H^0)\cdot B(H^0 \to \pi^0\pi^0) < 8 \times 10^{-5}$ at CL=90% for $m_{H^0} = 0.6$–1 GeV which is still far from the standard Higgs model prediction and does not exclude the existence of light Higgs bosons.

none 1.0–3.6	90	[41] ALAM	89B	CLEO	$B \to H^0 X$ $(H^0 \to \mu^+\mu^-)$
none 3.6–4.6		[42] EILAM	89	RVUE	$B \to H^0 X$ $(H^0 \to \mu^+\mu^-)$
none 0.211–0.700		[43] RABY	89	RVUE	$B \to \mu^+\mu^- X$ $m_{top} > 80$ GeV
none 0.07–0.21	90	[44] SNYDER	89	MRK2	$B \to H^0 X$ $(H^0 \to e^+e^-)$
none 0.00103–3.57		[43] CHIVUKULA	88	RVUE	$B \to H^0 X$, $m(\text{top}) > 80$ GeV
none 2–3.7		[43] GRINSTEIN	88	RVUE	$B \to H^0 X$, $m(\text{top}) > 80$ GeV

[40] Based on ALTHOFF 84G, ALAM 89B, and ALBRECHT 87D. Some processes considered require the assumption $B(B \to H^0 K)/B(B \to H^0 X) > 0.01$. Other processes require theoretical assumptions regarding $B(H \to \pi^+\pi^-)$ when considering masses in the interval 0.9–1.2 GeV.

[41] ALAM 89B searched for inclusive and exclusive decays of B mesons into H^0 and can exclude the mass range $2m_\mu$–$2m_\tau$ with a wide margin provided $m_t \gtrsim m_W$, possibly except for masses near $\chi_0(3410)$, where the mixing effect can reduce $B(H^0 \to \mu^+\mu^-)$ significantly.

[42] EILAM 89 assume $m_{top} > 90$ GeV and vary $|V_{ub}/V_{cb}|^2$ from 0 to 0.026.

[43] Limits assume $m(\text{top}) > 80$ GeV and $|V_{ts}V^*_{tb}/V_{cb}| \approx 1$. CHIVUKULA 88 excludes m_{H^0} between $2m_e$ and $2m_\tau$ from the limits on $B \to \mu^+\mu^- + X$ by taking the $B(H^0 \to \mu^+\mu^-)$ estimate of VOLOSHIN 86. GRINSTEIN 88 argues that this estimate of VOLOSHIN 86 is unreliable, and excludes m_{H^0} between 2 GeV and 3.7 GeV where perturbative QCD is used to estimate $B(H^0 \to \mu^+\mu^-)$.

[44] SNYDER 89 exclude the mass range 70–210 MeV with a wide margin provided that $m_t \gtrsim m_W$. A limit $B(B \to H^0 X)\cdot B(H^0 \to e^+e^-) < 22\%$ (90% CL) is given for $m_{H^0} = 50$ MeV.

>0.28		[51] CHENG	89	RVUE	$K^\pm \to \pi^\pm H$
>0.36		[52] CHIVUKULA	88	RVUE	$K \to \pi^+ H^0$
	90	[53] BAKER	87	CALO	$K^\pm \to \pi^\pm H^0$ $(H^0 \to e^+e^-)$
none 0.05–0.211		[54] WILLEY	86	RVUE	$K^\pm \to \pi^\pm H^0$ $(H^0 \to e^+e^-)$

[45] ATIYA 90 sets limits on $B(K^+ \to \pi^+ H^0)$ varying from $< 6.4 \times 10^{-9}$ for $m_{H^0} \approx 0$ MeV to $< 10^{-6}$ for $m_{H^0} = 26$ MeV.

[46] ATIYA 90B give 90% CL limits on $B(K^+ \to \pi^+ H^0)\cdot B(H^0 \to \gamma\gamma)$ for $m_{H^0} < 100$ MeV ranging from 10^{-4} to 10^{-7} depending on the mass.

[47] BARR 90 set m_{H^0}-dependent limits on $B(K^0_L \to \pi^0 H^0)$ in the region where $B(H^0 \to e^+e^-) \approx 1$. The limit varies from $B(K^0_L \to \pi^0 H^0) < 10^{-7}$ at $m_{H^0} = 12$ MeV to $< 2 \times 10^{-8}$ for $50 \le m_{H^0} \le 211$ MeV. BARR 90 allow for nonzero H^0 lifetime.

[48] Based on ASANO 81B, YAMAZAKI 84, BAKER 87, ATIYA 89, and BARR 90. DAWSON 90 used theoretical calculations and various assumptions such as $m_t > 80$ GeV and $\text{Im}\, V^*_{td}V_{ts} > 0.2 \sin^5\theta_c$.

[49] LEUTWYLER 90 give a consistent analysis of the $K \to \pi H^0$ amplitude based on chiral theory and find that all contributions except the t-quark loop are unimportant numerically provided the t-quark mass is of order or bigger than 100 GeV. Hence, a light Higgs can probably be ruled out.

[50] ATIYA 89 give a limit $B(K^+ \to \pi^+ H^0)\cdot B(H^0 \to \mu^+\mu^-) < 1.5 \times 10^{-7}$ (90% CL) for $m_{H^0} = 220$–320 MeV, which is lower than the prediction unless there is an accidental cancellation in the CP-conserving part of the amplitude and the CP-violating part is unexpectedly small. See WILLEY 89 and CHENG 89.

[51] CHENG 89 concludes even if real part of $K^+ \to \pi^+ H$ amplitude is cancelled accidentally, the imaginary contribution alone rules out $m_H < 2m_\pi$.

[52] CHIVUKULA 88 uses chiral perturbation theory to estimate $K \to \pi^+ H^0$ amplitudes with a conservative sign assignment for the relative sign of the $\Delta I = 1/2$ term, and exclude m_{H^0} below 0.36 GeV barring cancellation among terms, by using the limits on $K \to \pi^+ X$ with $X = \mu^+\mu^-$, e^+e^-, or missing particles. For a criticism see DAWSON 90.

[53] BAKER 87 sets limit $B(K^\pm \to \pi^\pm H^0)\cdot B(H^0 \to e^+e^-) < 8 \times 10^{-7}$ at CL=90% for $m_{H^0} < 100$ MeV if H^0 travels much less than 1.4 cm in the lab frame ($p(K^+) = 5.8$ GeV). The expected lifetime of the standard H^0 is too long to be effectively detected by the experiment and their limit on the branching ratio is significantly weakened accordingly. In view of the uncertainty in the theoretical prediction for $B(K \to \pi H)$, no definite conclusion can be drawn from the result. See also DAWSON 90.

[54] WILLEY 86 re-examined the theoretical estimate of the decay $K^\pm \to \pi^\pm H^0$ rate via the one-loop $s\,d\,H^0$ coupling. The experimental bound $B(K \to \pi\mu\mu) < 2.4 \times 10^{-6}$ is not strong enough to rule out $2m_\mu < m_{H^0} < 2m_{\pi^0}$. For a criticism see DAWSON 90.

From Coupling with Nucleons

Some of the experiments for a light Higgs utilize its coupling with nucleons. We parameterize the Higgs-nucleon coupling (which is dominantly isoscalar) as $g_{HNN} = \eta_{HNN}(\sqrt{2}G_F)^{1/2} m_N$. The limits depend on the value of η_{HNN} used. Shifman *et al.* [Physics Letters **78B** 443 (1978)] obtained $\eta_{HNN} = 0.22$ assuming three heavy flavors. More recently, T.P. Cheng [Physical Review **D38** 2869 (1988)], H.-Y. Cheng [Physics Letters **B219** 347 (1989)], and Barbieri and Curci [Physics Letters **B219** 503 (1989)] took into account the strange-quark content of the proton as well as the heavy quark effects, and derived $\eta_{HNN} = 0.56$.

[55] BLUEMLEIN 92 exclude very light Standard Model Higgs using bremsstrahlung Higgs production from beam dump followed by Bethe-Heitler production of lepton pairs by H^0 on nuclei. If combined with BLUEMLEIN 91, the range $m_H < 0.08$ GeV is excluded.

[56] LEEB 92 use the neutron-lead total cross section measurement by SCHMIEDMAYER 91 as well as neutron optics data to obtain bounds on new long-range neutron interactions. The limit uses $\eta_{HNN} = 0.56$.

[57] GRIFOLS 89 use the neutron-lead total cross-section measurement at kinetic energies of 50 eV – 50 keV by SCHMIEDMAYER 88 and argue that the agreement of the measured energy dependence with the prediction of a hard-core potential model is lost by light-Higgs exchange. The limit of 18 MeV is obtained for $\eta_{HNN} = 0.56$ and is reduced to 12 MeV for $\eta_{HNN} = 0.22$. LEEB 92 argue against the use of a hard-core potential and obtain a weaker limit.

[58] YEPES 89B reanalyzed a Fermilab experiment (BECHIS 78), which looked for a long-lived neutral lepton and found none, and argues that their limit is many orders of magnitude lower than expected from low-mass Higgs bremsstrahlung production followed by the decay to e^+e^-.

[59] BELTRAMI 86 measured the wavelengths of the $3d_{5/2}-2p_{3/2}$ X-ray transitions in muonic ^{24}Mg and ^{28}Si and found the deviation from QED $\delta\lambda/\lambda = (-0.2\pm3.1)\times10^{-6}$. The listed limit uses $\eta_{HNN} = 0.23$. The experiment excludes $m_{H^0} \lesssim 1$ MeV by more than 3 s.d.

[60] FREEDMAN 84 is ANL experiment with dynamitron proton bombarding tritium to form He*. $\eta_{HNN} = 0.30$ is used to derive the limit . They also reanalyze KOHLER 74 He* data to find no mass region is excluded by that data. See also footnote for MUKHOPADHYAY 84 below.

[61] MUKHOPADHYAY 84 examine KOHLER 74 He* and C* data. Claim that no mass region can be excluded by 74 He* data since He* decay width to proton is large [B(He* $\to$ H^0He) $= 3.4\times10^{-11}$ is very small]. Above limit is from KOHLER 74 O* decay data.

[62] HOFFMAN 83 looked for e^+e^- peak from Higgs produced in $\pi^- p \to H^0 n$ at 300 MeV/c. Set CL = 90% limit $d\sigma/dt$ B(e^+e^-) $< 3.5\times10^{-32}$ cm^2/GeV^2 for 140 $< m_{H^0} <$160 MeV, which does not exclude H^0 with the standard one-doublet-model couplings.

[63] BARBIERI 75 studied Higgs boson exchange effect in neutron-lead scattering data of ALEKSANDROV 66 and found limit $(g^2_{H^0nn}/4\pi)\,(m_{H^0}/\text{MeV})^{-4} \lesssim 3.4\times10^{-11}$ for $m_{H^0} \gtrsim 1$ MeV. This gives the listed limit for $\eta_{HNN} = 0.2$ and 10 MeV for $\eta_{HNN} = 0.56$. Lighter mass region $m_{H^0} \lesssim 1$ MeV would be incompatible with the measured angular distribution.

From Other Techniques

none 0.015–0.04	90	[67] YEPES	89	RVUE	$\pi^\pm \to e^\pm\nu H^0$ ($H^0 \to e^+e^-$)
		[68] DZHELYADIN	81		$\eta' \to \eta H^0$ ($H^0 \to \mu^+\mu^-$)
		[69] WITTEN	81	COSM	
		[69] GUTH	80	COSM	
		[69] SHER	80	COSM	

[64] BARABASH 92 is a beam dump experiment that searched for $H^0 \to e^+e^-$ and $\gamma\gamma$ produced via the decays $\pi \to e\nu_e H^0$, $K \to e\nu_e H^0$, $K \to \pi H^0$, and $\eta' \to \eta H^0$. The last process gives the best limit if the theoretical calculation by RUSKOV 87 is used.

[65] EGLI 89 give a limit for B($\pi^+ \to e^+\nu H^0$)·B($H^0 \to e^+e^-$) ranging from 10^{-9} to 10^{-11} for the mass range 10–110 MeV. The theoretical prediction they use is too large by a factor of 162/49 (see DAWSON 89, DAWSON 90, and CHENG 89). The lower limit given above is reevaluated by us.

[66] LINDNER 89 require vacuum stability and numerically solve the renormalization equations to two-loop order. If $m_{top} = 100, 110, 120$ GeV, then $m_{Higgs} > 20, 34, 50$ GeV. However, it is possible that the vacuum is not stable but is very long-lived.

[67] YEPES 89 reanalyzed a BNL beam-dump experiment (JACQUES 80) which looked for electron pairs in 7 foot BC downstream from the dump and found none.

[68] DZHELYADIN 81 obtained B($\eta' \to \eta\mu^+\mu^-$) $< 1.5\times10^{-5}$ (CL = 90%), and argued that it excludes H^0 with the standard one-doublet-model couplings in $\mu^+\mu^-$ channel for $m_{H^0} = 0.25$–0.409 GeV. However, the number 0.409 is not well-determined due to theoretical uncertainties in B($H^0 \to \mu^+\mu^-$).

[69] Limits from cosmological considerations of SU(2)×U(1) symmetry-breaking phase transition occurring only after extreme supercooling, resulting in too high a ratio of entropy to baryon number. Limits apply to the standard one-doublet model H^0, with 'zero bare mass' whose physical mass is determined by the Coleman-Weinberg mechanism of dynamical symmetry breakdown. These limits depend on the mass of the top quark approximately according to $m_{H^0} > 10.4[1-4m_t^4/(2m_W^4+m_Z^4)]^{1/2}$ GeV when $m_t < 80$ GeV. So for $m_t \approx 80$ GeV, there is no limit. If $m_t > 80$ GeV, then vacuum stability arguments may give bounds on m_H, see LINDNER 89 above.

H^0 (Higgs Boson) MASS LIMITS in Extended Higgs Models

The parameter x denotes the Higgs coupling to charge $-1/3$ quarks and charged leptons relative to the value in the standard one-Higgs-doublet model.

In order to prevent flavor-changing neutral currents in models with more than one Higgs doublet, only one of the Higgs doublets can couple to quarks of charge 2/3. The same requirement applies independently to charge $-1/3$ quarks and to leptons. Higgs couplings can be enhanced or suppressed.

[70] BRAHMACHARI 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. If H^0 coupling to Z is at least $1/\sqrt{2}$ of the Standard Model H^0, the DECAMP 92 limit of 48 GeV changes within ±6 GeV for arbitrary B($H^0 \to$ SM-like)+B($H^0 \to$ invisible)=1.

[71] See Fig. 1 of BUSKULIC 93I for the limit on ZZH^0 coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson or decaying invisibly. If the decay rate for $Z \to H^0 Z^*$ is >10% of the minimal Standard Model rate, then $m_{H^0} >$40 GeV. For the standard rate the limit is 58 GeV.

[72] BUSKULIC 93I limit for H^0 with the standard coupling to Z but decaying to weakly interacting particles.

[73] LOPEZ-FERNANDEZ 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. See Fig. 2 for excluded region in m_{H^0}-ZZH coupling plane with arbitrary B($H^0 \to$ SM-like)+B($H^0 \to$ invisible)=1. $m_H >$50 GeV is obtained if the H^0 coupling strength to the Z is greater than 0.2 times the Standard Model rate.

[74] See Fig. 1 of ADRIANI 92G for the limit on ZZH^0 coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson. For most masses below 30 GeV, the rate for $Z \to H_1^0 Z^*$ is less than 10% of the Standard Model rate.

[75] PICH 92 analyse H^0 with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm$, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

[76] ACTON 91 limit is valid for any H^0 having $\Gamma(Z \to H^0 Z^*)$ more than 0.24 (0.56) times that for the standard Higgs boson for Higgs masses below $2m_\mu$ ($2m_\tau$).

[77] DECAMP 91F search for $Z \to H^0\ell^+\ell^-$ where H^0 escapes before decaying. Combining this with DECAMP 90M and DECAMP 90N, they obtain B($Z \to H^0\ell^+\ell^-$)/B($Z \to \ell^+\ell^-$) $< 2.5\times10^{-3}$ (95%CL) for $m_{H^0} <$ 60 GeV.

[78] See Figs. 1, 3, 4, 5 of DECAMP 91I for excluded regions for the masses and mixing angles in general two-doublet models.

[79] AKRAWY 90P limit is valid for any H^0 having $\Gamma(Z \to H^0 Z^*)$ more than 0.57 times that for the Standard Higgs boson.

[80] DAVIER 89 give excluded region in m_{H^0}-x plane for m_{H^0} ranging from 1.2 MeV to 50 MeV.

[81] SNYDER 89 give limits on B($B \to H^0 X$)·B($H^0 \to e^+e^-$) for 100 $< m_{H^0} <$ 200 MeV, $c\tau <$ 24 mm.

[82] First order QCD correction included with $\alpha_s \approx 0.2$. Their figure 4 shows the limits vs. x.

[83] ALBRECHT 85J found no mono-energetic photons in both $\Upsilon(1S)$ and $\Upsilon(2S)$ radiative decays in the range 0.5 GeV $< E(\gamma) <$4.0 GeV with typically BR< 0.01 for $\Upsilon(1S)$ and BR< 0.02 for $\Upsilon(2S)$ at 90% CL. These upper limits are 5–10 times the prediction of the standard Higgs-doublet model. The quoted 90% limit B($\Upsilon(1S) \to H^0\gamma$) $< 1.5\times10^{-3}$ at $E(\gamma) = 1.07$ GeV contradicts previous Crystal Ball observation of $(4.7\pm1.1)\times10^{-3}$; see their reference 3. Their figure 8a shows the upper limits of x^2 as a function of $E(\gamma)$ by assuming no QCD corrections. We used $m_{H^0} = m_\Upsilon\,(1-2E(\gamma)/m_\Upsilon)^{1/2}$.

H_1^0 (Higgs Boson) MASS LIMITS in Supersymmetric Models

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar (A^0), and a charged Higgs pair ($H^\pm$). There are two free parameters in the theory which can be chosen to be m_{A^0} and $\tan\beta = \nu_2/\nu_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \le m_Z$, $m_{H_2^0} \ge m_Z$, $m_{A^0} \ge m_{H_1^0}$, and $m_{H^\pm} \ge m_W$. However, as describe in the "Note on Supersymmetry," recent calculations of one-loop radiative corrections show that these relations may be violated. Many experimental analyses have not taken into account these corrections; footnotes indicate when these corrections are included. The results assume no invisible H^0 or A^0 decays.

[84] BUSKULIC 93I search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections are included with any m_t, $m_{\tilde{t}} > m_t$. Assumes no invisible H^0 or A^0 decays.

[85] ABREU 92J searched for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$ with $H_1^0, A^0 \to \tau\tau$ or jet-jet. Small mass values are excluded by ABREU 91B.

[86] ADRIANI 92G search for $Z \to H_1^0 Z^*$, $Z \to H_1^0 A^0 \to 4b$, $bb\tau\tau$, 4τ, $6b$ (via $H^0 \to A^0 A^0$), and include constraints from $\Gamma(Z)$. One-loop corrections to the Higgs potential are included with $90 < m_t < 250$ GeV, $m_t < m_{\tilde{t}} < 1$ TeV.

[87] AKRAWY 91C result from $Z \to H_1^0 A^0 \to$ 4jet or $\tau^+\tau^- jj$ or 4τ and $Z \to H_1^0 Z^*$ ($H_1^0 \to q\bar{q}$, $Z^* \to \nu\bar{\nu}$ or e^+e^- or $\mu^+\mu^-$). See paper for the excluded region for the case $\tan\beta < 1$. Although these limits do not take into account the one-loop radiative corrections, the authors have reported unpublished results including these corrections and showed that the excluded region becomes larger.

[88] ABREU 91B result is based on negative search for $Z \to H_1^0 f\bar{f}$ and the limit on invisible Z width $\Gamma(Z \to H_1^0 A^0) < 39$ MeV (95%CL), assuming $m_{A^0} < m_{H_1^0}$.

[89] ABREU 91B result obtained by combining with analysis of ABREU 90I.

[90] BLUEMLEIN 91 excluded certain range of $\tan\beta$ for $m_{H_1^0} < 120$ MeV, $m_{A^0} < 80$ MeV.

[91] DECAMP 91I searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to$ 4jets or $\tau\tau jj$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied top and squark masses.

[92] ABREU 90E searched for $Z \to H_1^0 A^0$ and $Z \to H_1^0 Z^*$. $m_{H_1^0} < 210$ MeV is not excluded by this analysis.

[93] ADEVA 90R result is from $Z \to H_1^0 A^0 \to$ 4jet or $\tau\tau jj$ or 4τ and $Z \to H_1^0 Z^*$. Some region of $m_{H_1^0} < 4$ GeV is not excluded by this analysis.

[94] DECAMP 90E look for $Z \to H_1^0 A^0$ as well as $Z \to H_1^0 \ell^+\ell^-$, $Z \to H_1^0 \nu\bar{\nu}$ with 18610 Z decays. Their search includes signatures in which H_1^0 and A^0 decay to $\gamma\gamma$, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, or $q\bar{q}$. See their figures of $m_{H_1^0}$ vs. $\tan\beta$.

[95] DECAMP 90H is similar to DECAMP 90E but with 25,000 Z decays.

[96] DECAMP 90M looked for $Z \to H^0 \ell\ell$, where H_1^0 decays outside the detector. This excludes a region in the ($m_{H_1^0}$, $\tan\beta$) plane centered at $m_{H_1^0} = 50$ MeV, $\tan\beta = 0.5$. This limit together with DECAMP 90E result excludes $m_{H_1^0} < 3$ GeV for any $\tan\beta$.

>39	95	[105] ADEVA	90R	L3	$\tan\beta > 1$, $m_{H_1^0} < m_{A^0}$

[97] BUSKULIC 93I search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections to the Higgs potential are included with any m_t, $m_{\tilde{t}} > m_t$. For $m_t = 140$ GeV and $m_{\tilde{t}} = 1$ TeV, the limit is $m_{A^0} > 45$ GeV. Assumes no invisible H^0 or A^0 decays.

[98] ABREU 92J searched for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$ with $H_1^0, A^0 \to \tau\tau$ or jet-jet. Small mass values are excluded by ABREU 91B.

[99] ADRIANI 92G search for $Z \to H_1^0 Z^*$, $Z \to H_1^0 A^0 \to 4b$, $bb\tau\tau$, 4τ, $6b$ (via $H^0 \to A^0 A^0$), and include constraints from $\Gamma(Z)$. One-loop corrections are included with $90 < m_t < 250$ GeV, $m_t < m_{\tilde{t}} < 1$ TeV. The region $m_{A^0} < 11$ GeV is allowed if $42 < m_{H_1^0} < 62$ GeV, but is excluded by other experiments.

[100] AKRAWY 91C result from $Z \to H_1^0 A^0 \to$ 4jet or $\tau^+\tau^- jj$ or 4τ. See paper for the excluded region for the case $\tan\beta < 1$.

[101] ABREU 90E searched $Z \to H_1^0 A^0$ and $Z \to H_1^0 Z^*$. $m_{A^0} < 210$ MeV is not excluded by this analysis.

[102] ELLIS 93 analyze possible constraints on the MSSM Higgs sector by electroweak precision measurements and find that m_{A^0} is not constrained by the electroweak data.

[103] BUSKULIC 92 limit is from $\Gamma(Z)$, $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0$. The limit is valid for any $m_{H_1^0}$ below the the theoretical limit $m_{H_1^0} < 64$ GeV which holds for $m_{A^0} \sim 0$ in the minimal supersymmetric model. One-loop radiative corrections are included.

[104] DECAMP 91I searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to$ 4jets or $\tau\tau jj$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied top and squark masses. For $m_t = 140$ GeV and $m_{\tilde{q}} = 1$ TeV, the limit is $m_{A^0} > 31$ GeV.

[105] ADEVA 90R result is from $Z \to H_1^0 A^0 \to$ 4jet or $\tau\tau jj$ or 4τ and $Z \to H_1^0 Z^*$. Some region of $m_{A^0} < 5$ GeV is not excluded by this analysis.

MASS LIMITS for Associated Higgs Production in e^+e^- Interactions

In multi-Higgs models, associated production of Higgs via virtual or real Z in e^+e^- annihilation, $e^+e^- \to H_1^0 H_2^0$, is possible if H_1^0 and H_2^0 have opposite CP eigenvalues. Limits are for the mass of the heavier Higgs H_2^0 in two-doublet models.

none 1–9	90	[111] FELDMAN	85	MRK2	$m_{H_1^0} = m_{H_2^0}$, $H_2^0 \to f\bar{f}$

[106] ADRIANI 92G excluded regions of the $m_{H_1^0} - m_{A^0}$ plane for various decay modes with limits $B(Z \to H_1^0 H_2^0) < (2\text{–}20) \times 10^{-4}$ are shown in Figs. 2–5.

[107] DECAMP 90H search for $Z \to H_1^0 e^+e^-$, $H_1^0 \mu^+\mu^-$, $H_1^0 \tau^+\tau^-$, $H_1 q\bar{q}$, low multiplicity final states, τ-τ-jet-jet final states and 4-jet final states.

[108] KOMAMIYA 90 limits valid for $\cos^2(\alpha - \beta) \approx 1$. They also search for the cases $H_1^0 \to \mu^+\mu^-$, $\tau^+\tau^-$, and $H_2^0 \to H_1^0 H_1^0$. See their Fig. 2 for limits for these cases.

[109] KOMAMIYA 89 assume $B(H_1^0 \to \mu^+\mu^-) = 100$ %, $2m_\mu < m_{H_1^0} < m_\tau$. The limit is for maximal mixing. A limit of $m_{H_2^0} > 18$ GeV for the case $H_2^0 \to H_1^0 H_1^0$ ($H_1^0 \to \mu^+\mu^-$) is also given. From PEP at $E_{cm} = 29$ GeV.

[110] LOW 89 assume that H_1^0 escapes the detector. The limit is for maximal mixing. A reduced limit of 24 GeV is obtained for the case $H_2^0 \to H_1^0 f\bar{f}$. Limits for a Higgs-triplet model are also discussed. $E_{cm}^{ee} = 50$–60.8 GeV.

[111] The limit assumes maximal mixing and that H_1^0 escapes the detector.

[112] ASH 85 assumes that H_1^0 escapes undetected. The bound applies up to a mixing suppression factor of 5.

$H^\pm$ (Charged Higgs or Techni-pion) MASS LIMITS

Most of the following limits assume $B(H^+ \to \tau^+\nu) + B(H^+ \to c\bar{s}) = 1$. DECAMP 90I, BEHREND 87, and BARTEL 86 assume $B(H^+ \to \tau^+\nu) + B(H^+ \to c\bar{s}) + B(H^+ \to c\bar{b}) = 1$. All limits from Z decays as well as ADACHI 90B assume that H^+ has weak isospin $T_3 = +1/2$. For a discussion of techni-particles, see EICHTEN 86.

[113] ADRIANI 92G limit improves to 44 GeV if $B(\tau\nu_\tau) > 0.4$.

[114] Studied $H^+H^- \to (\tau\nu) + (\tau\nu)$, $H^+H^- \to (\tau\nu)$ + hadrons, $H^+H^- \to$ hadrons.

[115] DECAMP 92 limit improves to 45.3 GeV for $B(\tau\nu)$=1.

[116] HEWETT 93 and BARGER 93 analyze charged Higgs contribution to $b \to s\gamma$ in two-doublet models with the CLEO limit $B(b \to s\gamma) < 8.4 \times 10^{-4}$ (90% CL) and find lower limits on $m_{H^\pm}$ in the type of model (model II) in which different Higgs are responsible for up-type and down-type quark masses. HEWETT 93 give $m_{H^+} > 110$ (70) GeV for $m_t > 150$ (120) GeV using $m_b = 5$ GeV. BARGER 93 give $m_{H^+} > 155$ GeV for $m_t = 150$ GeV using $m_b = 4.25$ GeV. The authors employ leading logarithmic QCD corrections and emphasize that the limits are quite sensitve to m_b.

[117] BELANGER 93 make an analysis similar to BARGER 93 and HEWETT 93 with an improved CLEO limit $B(b \to s\gamma) < 5.4 \times 10^{-4}$ (95%CL). For the Type II model, the limit $m_{H^+} > 540$ (300) GeV for $m_t > 150$ (120) GeV is obtained. The authors employ leading logarithmic QCD corrections.

[118] ALITTI 92F search for $t \to bH^+$, $H^+ \to \tau\nu_\tau$ with τ decaying hadronically in $p\bar{p}$ collisions at $E_{cm} = 630$ GeV. m_{H^+} between 40 and 65 GeV is excluded if $m_t - m_H = m_b + (\lesssim$ a few–10 GeV). See Figs. 5, 6 for the excluded region for $B(H^+ \to \tau\nu_\tau) = 1, 0.5$.

[119] ALBAJAR 91B search for $W \to t\bar{b}$ and $t\bar{t}$ production in $p\bar{p}$ collisions with the decay chain $t \to H^+b$, $H^+ \to \tau^+\nu$, in single muon plus jets and dimuon channels. For $m_t = 60$ GeV, $m_{H^+} < 47$ GeV is excluded at 95%CL if $\tan\beta > 2.3$. The search is restricted to small values of m_t, and no limit on m_{H^+} is obtained if $m_t > 61$ GeV. Note that existing limits on m_t are not valid if $t \to H^+b$.

[120] YUZUKI 91 assume photon exchange. The limit is valid for any decay mode $H^+ \to e\nu$, $\mu\nu$, $\tau\nu$, $q\bar{q}$ with five flavors. For $B(\ell\nu) = 1$, the limit improves to 25.0 GeV.

[121] ABREU 90B limit improves to 36 GeV for $B(\tau\nu) = 1$.

[122] ADACHI 90B limit improves to 22 GeV for $B(\tau\nu) = 0.6$.

[123] ADEVA 90M limit improves to 42.5 GeV for $B(\tau\nu) = 1$.

[124] AKRAWY 90K limit improves to 43 GeV for $B(\tau\nu) = 1$.

[125] If $B(H^+ \to \tau^+\nu) = 100\%$, the DECAMP 90I limit improves to 43 GeV.

[126] SMITH 90B limit applies for $v_2/v_1 > 2$ in a model in which H_2 couples to u-type quarks and charged leptons.

[127] Studied $H^+H^- \to (\tau\nu) + (\tau\nu)$, $H^+H^- \to (\tau\nu)$ + hadrons. Search for muon opposite hadronic shower.

MASS LIMITS for $H^{\pm\pm}$ (doubly-charged Higgs boson)

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>45.6	95	[128] ACTON	92M	OPAL	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>30.4	95	[128] ACTON	92M	OPAL	$T_3(H^{++}) = +1$
>25.5	95	[129] ACTON	92M	OPAL	$T_3(H^{++}) = 0$
none 6.5–36.6	95	[130] SWARTZ	90	MRK2	$T_3(H^{++}) = +1$
none 7.3–34.3	95	[130] SWARTZ	90	MRK2	$T_3(H^{++}) = 0$

[128] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[129] ACTON 92M from $\Delta\Gamma_Z < 40$ MeV.

[130] SWARTZ 90 assume $H^{\pm\pm} \to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

Gauge & Higgs Boson Full Listings

Heavy Bosons Other than Higgs Bosons

Searches for Heavy Bosons Other Than Higgs Bosons

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the W_L-W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+.

[2] BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t=200 GeV and slightly improves for smaller m_t.

[3] SEVERIJNS 93 measured polarization-asymmetry correlation in ^{107}In β^+ decay. The value $R/R_0 = 0.926 \pm 0.041$ is 1.7 standard deviations away from the Standard Model expectation, giving $[m_1^2/m_2^2 + \zeta]^2 = 0.087 \pm 0.051$. The listed limit assumes zero L-R mixing.

[4] IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+\nu_\mu$ decay and obtain $\xi P_\mu > 0.990$ (90%CL). If W_R couples to $u\bar{s}$ with full weak strength (V_{us}^R=1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$.

[5] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Supersedes POLAK 91.

[6] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

[7] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

[8] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Superseded by POLAK 92B.

[9] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[10] LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

[11] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.

[12] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.

[13] BERGSMA 83 set limit m_{W_2}/m_{W_1} >1.9 at CL = 90%.

[14] CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is m_{W_R} >240 GeV. Assumes a light right-handed neutrino.

[15] BEALL 82 limit is obtained assuming that W_R contribution to K_L^0-K_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L-W_R Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L \cos\zeta - W_R \sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 0.04	90	[16] MISHRA	92	CCFR	νN scattering

−0.056 to 0.040	90	[19] JODIDIO	86	ELEC	μ decay

[16] MISHRA 92 limit is from the absence of extra large-x, large-y $\bar{\nu}_\mu N \to \bar{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\bar{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m_{W_1}^2/m_{W_2}^2) < 0.0015$. The limit is independent of ν_R mass.

[17] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.

[18] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[19] First JODIDIO 86 result assumes $m_{W_R} = \infty$, second is for unconstrained m_{W_R}.

MASS LIMITS for W' (A Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\bar{p} \to W'X$ with W' decaying to the mode indicated in the comments. Experiments other than ABE 91F assume no new decay channels (esp. $t\bar{b}$) are open.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>520	95	[20] ABE	91F	CDF	$W' \to e\nu, \mu\nu$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>251	90	[21] ALITTI	93	UA2	$W' \to q\bar{q}$
none 260–600	95	[22] RIZZO	93	RVUE	$W' \to q\bar{q}$
none 101–158	90	[23] ALITTI	91	UA2	$W' \to q\bar{q}$
>220	90	[24] ALBAJAR	89	UA1	$W' \to e\nu$
>209	90	[25] ANSARI	87D	UA2	$W' \to e\nu$
>210	90	[26] ARNISON	86B	UA1	$W' \to e\nu$
>170	90	[27] ARNISON	83D	UA1	$W' \to e\nu$

[20] ABE 91F assume leptonic branching ratio of 1/12 for each lepton flavor. The limit from the $e\nu$ ($\mu\nu$) mode alone is 490 (435) GeV. These limits apply to W_R if $m_{\nu_R} \lesssim 15$ GeV and ν_R does not decay in the detector. Cross section limit $\sigma \cdot B < (1\text{–}10)$ pb is given for $m_{W'} = 100$–550 GeV; see Fig. 2.

[21] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $\Gamma(W')/m_{W'} = \Gamma(W)/m_W$ and $B(W' \to jj) = 2/3$. This corresponds to W_R with $m_{\nu_R} > m_{W_R}$ (no leptonic decay) and $W_R \to t\bar{b}$ allowed. See their Fig. 4 for limits in the $m_{W'}$–$B(q\bar{q})$ plane.

[22] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

[23] ALITTI 91 search is based on two-jet invariant mass spectrum, assuming $B(W' \to q\bar{q}) = 67.6\%$. Limit on $\sigma \cdot B$ as a function of two-jet mass is given in Fig. 7.

[24] ALBAJAR 89 cross section limit at 630 GeV is $\sigma(W')\, B(e\nu) < 4.1$ pb (90% CL).

[25] See Fig. 5 of ANSARI 87D for the excluded region in the $m_{W'}$–$[(g_{W'q})^2\, B(W' \to e\bar{\nu})]$ plane. Note that the quantity $(g_{W'q})^2\, B(W' \to e\bar{\nu})$ is normalized to unity for the standard W couplings.

[26] ARNISON 86B find no excess at large p_T in 148 $W \to e\nu$ events. Set limit $\sigma \times B(e\nu) < 10$ pb at CL = 90% at E_{cm} = 546 and 630 GeV.

[27] ARNISON 83D find among 47 $W \to e\nu$ candidates no event with excess p_T. Also set $\sigma \times B(e\nu) < 30$ pb with CL = 90% at E_{cm} = 540 GeV.

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

NOTE ON THE Z' SEARCHES

The mass bounds depend on the gauge group and the gauge coupling of a Z' boson. The limits listed below are not exhaustive but include only typical Z' bosons that appear frequently in the literature. The following notations are used for these Z' bosons.

Z'_{SM}: Z'_{SM} is a clone of the Z and is introduced as a convenient way to gauge the limits rather than with a theoretical motivation. It is assumed to have exactly the same couplings as the Z but a different mass.

Left-right symmetric bosons: Z_{LR} is the extra neutral boson which appears in left-right symmetric models with the gauge group $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ or $SU(2)_L \times U(1)_R \times U(1)_{B-L}$, where $U(1)_R$ is the third component of $SU(2)_R$ and the weak hypercharge $Y = T_{3R} + \frac{1}{2}(B - L)$. The Z_{LR}

couples to $\alpha T_{3R} - (1/2\alpha)(B-L)$ with the coupling strength g' (the weak hypercharge gauge coupling). The parameter α is model dependent. For left-right symmetric coupling $g_L = g_R$, $\alpha = (1-2\sin^2\theta_W)^{1/2}/\sin\theta_W \approx 1.53$, which is used for the limits in the listing unless noted. Another typical case $\alpha = (2/3)^{1/2}$ is identical to Z_χ (discussed below) with the coupling $g_\chi = g'$.

E_6 bosons: Two new neutral gauge bosons appear in E_6 models. One is contained in the SO(10) subgroup and the other is not:

$$E_6 \longrightarrow SO(10) \times U(1)_\psi ,$$

$$SO(10) \longrightarrow SU(5) \times U(1)_\chi .$$

One Z' is assumed to be relatively light, which in general is a linear combination of the two:

$$Z_\beta = Z_\chi \cos\beta + Z_\psi \sin\beta .$$

The gauge quantum numbers of the ordinary quarks and leptons are shown in the table:

f	T_{3R}	Y	$B-L$	$\sqrt{24}Q_\chi$	$\sqrt{\frac{72}{5}}Q_\psi$	Q_η
ν_L, e_L^-	0	$-\frac{1}{2}$	-1	$+3$	$+1$	$+\frac{1}{6}$
ν_R	$+\frac{1}{2}$	0	-1	$+5$	-1	$+\frac{5}{6}$
e_R^-	$-\frac{1}{2}$	-1	-1	$+1$	-1	$+\frac{1}{3}$
u_L, d_L	0	$+\frac{1}{6}$	$+\frac{1}{3}$	-1	$+1$	$-\frac{1}{3}$
u_R	$+\frac{1}{2}$	$+\frac{2}{3}$	$+\frac{1}{3}$	$+1$	-1	$+\frac{1}{3}$
d_R	$-\frac{1}{2}$	$-\frac{1}{3}$	$+\frac{1}{3}$	-3	-1	$-\frac{1}{6}$

In particular, the χ charge is related to others by $\sqrt{24}Q_\chi = 4Y - 5(B-L)$. Also notice that the Z_ψ coupling is pure axial for all quarks and leptons.

Another typical case Z_η is defined as

$$Z_\eta = \sqrt{\tfrac{3}{8}}Z_\chi - \sqrt{\tfrac{5}{8}}Z_\psi ,$$

which appears in a superstring-motivated model.

A reference gauge coupling for these bosons is $g' = e/\cos\theta_W$, which is predicted if there is no intermediate symmetry breaking scale.

In general, these Z' models require the existence of a set of new fermions (belonging to the 27 representation of E_6) to cancel gauge anomalies, and possibly superpartners. An exception is Z_χ, for which only right-handed neutrinos are necessary. For the direct limits from hadron colliders, it is often assumed that these new fermions are heavy and are not produced in the decay of the Z'.

Limits for Z'_{SM}

Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z.

[28] LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t > 89$ GeV used.

[29] LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0086 < \theta < 0.0005$.

[30] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $B(Z' \to q\overline{q})$=0.7. See their Fig. 5 for limits in the $m_{Z'}$–$B(q\overline{q})$ plane.

[31] ALLEN 93 limit is from total cross section for $\nu e \to \nu e$, where $\nu = \nu_e, \nu_\mu, \overline{\nu}_\mu$.

[32] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

[33] ABE 91D give $\sigma(Z')\cdot B(e^+e^-) < 1.31$ pb (95%CL) for $m_{Z'} > 200$ GeV at $E_{cm} = 1.8$ TeV. Limits ranging from 2 to 30 pb are given for $m_{Z'} = 100$–200 GeV.

[34] GEIREGAT 91 limit is from comparison of g_V^e from $\nu_\mu e$ scattering with $\Gamma(Z \to ee)$ from LEP. Zero mixing assumed.

[35] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[36] HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries.

[37] ALBAJAR 89 cross section limit at 630 GeV is $\sigma(Z')\,B(ee) < 4.2$ pb (90% CL).

[38] See Fig. 5 of ANSARI 87D for the excluded region in the $m_{Z'}$–$[(g_{Z'q})^2\,B(Z' \to e^+e^-)]$ plane. Note that the quantity $(g_{Z'q})^2 B(Z' \to e^+e^-)$ is normalized to unity for the standard Z couplings.

[39] ARNISON 86B find no excess e^+e^- pairs among 13 pairs from Z. Set limit $\sigma \times B(e^+e^-) < 13$ pb at CL = 90% at $E_{cm} = 546$ and 630 GeV.

Limits for Z_{LR}

Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[40] These limits assume that Z' decays to known fermions only.

[41] LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t > 89$ GeV used.

[42] LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0025 < \theta < 0.0083$.

[43] ADRIANI 93D give limits on the Z-Z' mixing $-0.002 < \theta < 0.015$ assuming the ABE 92B mass limit.

[44] ALTARELLI 93B limit is from LEP data available in summer '93 and is for $m_t = 110$ GeV. $m_H = 100$ GeV and $\alpha_s = 0.118$ assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in Table 4.

[45] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

[46] These limits assume that Z' decays to all E_6 fermions and their superpartners.

[47] See Fig. 7b and 8 in DELAGUILA 92 for the allowed region in $m_{Z'}$-mixing plane and $m_{Z'} - m_t$ plane from electroweak fit including '90 LEP data.

[48] LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.

[49] POLAK 92 limit is from $m_{W_R} > 477$ GeV, which is derived from muon decay parameters assuming light ν_R. Specific Higgs sector is assumed.

Gauge & Higgs Boson Full Listings

Heavy Bosons Other than Higgs Bosons

[50] POLAK 92B limit is from a simultaneous fit to charged and neutral sector in $SU(2)_L \times SU(2)_R \times U(1)$ model using Z parameters, m_W, and low-energy neutral current data as of 1991. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Supersedes POLAK 91.

[51] RENTON 92 limits use LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. Specific Higgs structure is assumed.

[52] ALTARELLI 91B is based on Z mass, widths, and A_{FB}. The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H^0} < 1$ TeV assumed. For large m_t, the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the paper.

[53] DELAGUILA 91 bounds have extra assumption of superstring motivated Higgs sector. From νN neutral current data with $m_Z = 91.10 \pm 0.04$ GeV, $m_t > 77$ GeV, $m_{H^0} < 1$ TeV assumed.

[54] POLAK 91 limit is from a simultaneous fit to charged and neutral sector in $SU(2)_L \times SU(2)_R \times U(1)$ model using m_W, m_Z, and low-energy neutral current data as of 1990. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Superseded by POLAK 92B.

[55] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

[56] HE 90B model assumes a specific Higgs sector. Neutral current data of COSTA 88 as well as m_Z is used. g_R is left free in the fit.

[57] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[58] DELAGUILA 89 limit is based on $\sigma(p\overline{p} \to Z') \cdot B(Z' \to e^+e^-) < 1.8$ pb at CERN $p\overline{p}$ collider.

[59] A wide range of neutral current data as of 1986 are used in the fit.

[60] A wide range of neutral current data as of 1985 are used in the fit.

[61] ADEVA 85B measure asymmetry of μ-pair production, following formalism of RIZZO 81.

Limits for Z_χ

Z_χ is the extra neutral boson in $SO(10) \to SU(5) \times U(1)_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[62] These limits assume that Z' decays to known fermions only.

[63] LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t > 89$ GeV used.

[64] LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0048 < \theta < 0.0097$.

[65] BUSKULIC 94 give 95%CL limits on the Z-Z' mixing $-0.0091 < \theta < 0.0023$.

[66] ADRIANI 93D give limits on the Z-Z' mixing $-0.004 < \theta < 0.015$ assuming the ABE 92B mass limit.

[67] ALTARELLI 93B limit is from LEP data available in summer '93 and is for $m_t = 110$ GeV. $m_H = 100$ GeV and $\alpha_s = 0.118$ assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in their Fig. 2.

[68] These limits assume that Z' decays to all E_6 fermions and their superpartners.

[69] See Fig. 7a and 8 in DELAGUILA 92 for the allowed region in $m_{Z'}$-mixing plane and $m_{Z'} - m_t$ plane from electroweak fit including '90 LEP data.

[70] LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.

[71] LEIKE 92 is based on '90 LEP data published in LEP 92.

[72] RENTON 92 limits use LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. Specific Higgs structure is assumed.

[73] ALTARELLI 91B is based on Z mass, widths, and A_{FB}. The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H^0} < 1$ TeV assumed. For large m_t, the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the paper.

[74] BUCHMUELLER 91 limit is from LEP data. Specific assumption is made for the Higgs sector.

[75] DELAGUILA 91 bounds have extra assumption of superstring motivated Higgs sector. From νN neutral current data with $m_Z = 91.10 \pm 0.04$ GeV, $m_t > 77$ GeV, $m_{H^0} < 1$ TeV assumed.

[76] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.

[77] GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, Z mass and widths, m_W from ABE 90G. $100 < m_t < 200$ GeV, $m_{H^0} = 100$ GeV assumed. Dependence on m_t is shown in Fig. 7.

[78] MAHANTHAPPA 91 limit is from atomic parity violation in Cs with m_W, m_Z.

[79] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$.

[80] ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[81] e^+e^- data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{c\overline{c}}$ below Z as well as $\nu_\mu e$ scattering data of GEIREGAT 89 is used in the fit.

[82] BARGER 90B limit is based on CDF limit $\sigma(p\overline{p} \to Z') \cdot B(Z' \to e^+e^-) < 1$ pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.

[83] GLASHOW 90 model assumes a specific Higgs sector. See GLASHOW 90B.

[84] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).

[85] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

[86] HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries. The upper mass limit disappears at 2.7 s.d.

[87] DELAGUILA 89 limit is based on $\sigma(p\overline{p} \to Z') \cdot B(Z' \to e^+e^-) < 1.8$ pb at CERN $p\overline{p}$ collider.

[88] DORENBOSCH 89 obtain the limit $(g_\chi/g_Z)^2 \cdot (m_Z/m_{Z_\chi})^2 < 0.11$ at 95% CL from the processes $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ and $\nu_\mu e \to \nu_\mu e$.

[89] A wide range of neutral current data as of 1986 are used in the fit.

[90] Z' mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z' decays only into light quarks and leptons.

[91] MARCIANO 87 limit from unitarity of Cabibbo-Kobayashi-Maskawa matrix.

[92] A wide range of neutral current data as of 1985 are used in the fit.

Limits for Z_ψ

Z_ψ is the extra neutral boson in $E_6 \to SO(10) \times U(1)_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[101] e^+e^- data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{c\overline{c}}$ below Z as well as $\nu_\mu e$ scattering data of GEIREGAT 89 is used in the fit.

[102] BARGER 90B limit is based on CDF limit $\sigma(p\overline{p} \to Z') \cdot B(Z' \to e^+e^-) < 1$ pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.

[103] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).

[104] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also RIZZO 91.

[105] HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries.

[106] A wide range of neutral current data as of 1986 are used in the fit.

[107] A wide range of neutral current data as of 1985 are used in the fit.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8}\, Q_\chi - \sqrt{5/8}\, Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[108] These limits assume that Z' decays to known fermions only.

[109] LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. m_t >89 GeV used.

[110] LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.038 < \theta < 0.002$.

[111] ADRIANI 93D give limits on the Z-Z' mixing $-0.029 < \theta < 0.010$ assuming the ABE 92B mass limit.

[112] ALTARELLI 93B limit is from LEP data available in summer '93 and is for $m_t = 110$ GeV. $m_H = 100$ GeV and $\alpha_s = 0.118$ assumed. The 90%CL limit on the Z-Z' mixing angle is in Fig. 2.

[113] These limits assume that Z' decays to all E_6 fermions and their superpartners.

[114] See Fig. 7d in DELAGUILA 92 for the allowed region in $m_{Z'}$-mixing plane from electroweak fit including '90 LEP data.

[115] LAYSSAC 92B limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.

[116] LEIKE 92 is based on '90 LEP data published in LEP 92.

[117] RENTON 92 limits use LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. Specific Higgs structure is assumed.

[118] ALTARELLI 91B is based on Z mass, widths, and A_{FB}. The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H^0} < 1$ TeV assumed. For large m_t, the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the paper.

[119] GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, LEP Z mass and widths, m_W from ABE 90G. 100 $< m_t <$ 200 GeV, $m_{H^0} = 100$ GeV assumed. Dependence on m_t is shown in Fig. 8.

[120] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$.

[121] ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[122] e^+e^- data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{c\overline{c}}$ below Z as well as $\nu_\mu e$ scattering data of GEIREGAT 89 is used in the fit.

[123] BARGER 90B limit is based on CDF limit $\sigma(p\overline{p} \to Z')\cdot B(Z' \to e^+e^-) < 1$ pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.

[124] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).

[125] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

[126] HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries.

[127] DELAGUILA 89 limit is based on $\sigma(p\overline{p} \to Z')\cdot B(Z' \to e^+e^-) < 1.8$ pb at CERN $p\overline{p}$ collider.

[128] A wide range of neutral current data as of 1986 are used in the fit.

[129] Z_η mass limits obtained by combining constraints from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider and the global analysis of neutral current data by COSTA 88. Least favorable spectrum of three (E_6 27) generations of particles and their superpartners are assumed.

[130] Z' mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z' decays only into light quarks and leptons.

[131] BARGER 86B limit is based on UA1/UA2 limit on $p\overline{p} \to Z'$, $Z' \to e^+e^-$ (Lepton Photon Symp., Kyoto, '85). Extra decay channels for Z' are assumed not be open.

[132] A wide range of neutral current data as of 1985 are used in the fit.

Limits for other Z'

$Z_\beta = Z_\chi \cos\beta + Z_\psi \sin\beta$

VALUE (GeV)	CL%		DOCUMENT ID		TECN	COMMENT

>158	90	[140]	ELLIS	88	RVUE	Z_β ($\tan\beta = \sqrt{15}$), $p\overline{p}$

[133] Fig. 7c and 7e in DELAGUILA 92 give limits for $\tan\beta = -1/\sqrt{15}$ and $\sqrt{15}$ from electroweak fit including '90 LEP data.

[134] ALTARELLI 91 limit is from atomic parity violation in Cs together with LEP, CDF data. Z-Z' mixing is assumed to be zero to set the limit.

[135] MAHANTHAPPA 91 limit is from atomic parity violation in Cs with m_W, m_Z. See Table III of MAHANTHAPPA 91 (corrected in erratum) for limits on various Z' models.

[136] GRIFOLS 90C obtains a limit for Z' mass as a function of mixing angle β (his $\theta = \beta - \pi/2$), which is derived from a LAMPF experiment on $\sigma(\nu_e e)$ (ALLEN 90). The result is shown in Fig. 1.

[137] See Table I of DELAGUILA 89 for limits on various Z' models.

[138] $g_\beta = e/\cos\theta_W$ and $\rho = 1$ assumed.

[139] A wide range of neutral current data as of 1986 are used in the fit.

[140] Z' mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z' decays only into light quarks and leptons.

MASS LIMITS for Leptoquarks from Pair Production

These limits rely only on the color or electroweak charge of the leptoquark.

[141] ABACHI 94B search for $eejj$ and $e\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit is for scalar leptoquarks decaying with $B(eq)$=$B(\nu q)$=0.5 and improves to >133 GeV for $B(eq)$=1. This limit does not depend on the electroweak quantum numbers of the leptoquark.

[142] ABE 93I search for $\ell\ell jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit is for $B(eq) = B(\nu q) = 0.5$ and improves to >113 GeV for $B(eq) = 1$. This limit does not depend on electroweak quantum numbers of the leptoquark.

[143] Limit is for charge $-1/3$ isospin-0 leptoquark with $B(\ell q) = 2/3$.

[144] First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

[145] Limits are for charge $-1/3$, Isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.

[146] ADRIANI 93M limit for charge $-1/3$, isospin-0 leptoquark decaying to τb.

[147] ABREU 92F limit is for charge $-1/3$ isosin-0 leptoquark with $B(\mu q)$=2/3. If first and second generation leptoquarks are degenerate, the limit is 43.0 GeV, and for a charge 2/3 second generation leptoquark 43.4 GeV. Cross-section limit for pair production of states decaying to ℓq is given in the paper.

[148] ALITTI 92E search for $\ell\ell jj$ and $\ell\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=630 GeV. The limit is for $B(eq) = 1$ and is reduced to 67 GeV for $B(eq) = B(\nu q) = 0.5$. This limit does not depend on electroweak quantum numbers of the leptoquark.

[149] KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of de^+ and $u\overline{\nu}$ ($s\mu^+$ and $c\overline{\nu}$). See paper for limits for specific branching ratios.

[150] BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint $B(X \to c\overline{\nu}_\mu) + B(X \to s\mu^+) = 1$.

[151] BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ, decays either into $s\mu^+$ or $c\overline{\nu}$: $B(\chi \to s\mu^+) + B(\chi \to c\overline{\nu}) = 1$.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q-ℓ-leptoquark coupling g_{LQ}. It is often assumed that $g^2_{LQ}/4\pi$=1/137. Limits shown are for a scalar, weak isoscalar, charge $-1/3$ leptoquark.

VALUE (GeV)	CL%		DOCUMENT ID		TECN	COMMENT

[152] Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(\ell q) = 2/3$. The limit is 77 GeV if first and second leptoquarks are degenerate.

[153] ABT 93 search for single leptoquark production in ep collisions with the decays eq and νq. The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit for $B(eq) = 1$ is 178 GeV. For limits on states with different quantum numbers, see their Fig. 2.

[154] DERRICK 93 search for single leptoquark production in ep collisions with the decay eq and νq. The limit is for leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit for $B(eq) = 1$ is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

Indirect Limits for Leptoquarks

[158] ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.

[159] CUYPERS 91 compare α_s measured in Υ decay and that from R at PEP/PETRA energies.

[160] ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ ($\Gamma(g_A) = 0.09 m_{g_A}$). For $N = 10$, the excluded region is reduced to 120–150 GeV.

[161] ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\overline{t} \to t\overline{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5\ m_t$. Assumes $m_t > 56$ GeV.

[162] ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4\ m_{g_A}$ assumed. See also BAGGER 88.

[163] CUYPERS 88 requires $\Gamma(\Upsilon \to g g_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by DONCHESKI 88.

[164] DONCHESKI 88B requires $\Gamma(\Upsilon \to g q\overline{q})/\Gamma(\Upsilon \to ggg) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to $m_{g_A} > 21$ GeV.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, or a photon pair as shown in the comments. The limits are for the product of branching ratios.

$<8 \times 10^{-4}$	95	[172] AKRAWY	90J	OPAL	$X^0 \to$ hadrons

[165] ACTON 93E give $\sigma(e^+e^- \to X^0\gamma)\cdot B(X^0 \to \gamma\gamma) < 0.4$ pb (95%CL) for m_{X^0}=60 ± 2.5 GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0)\cdot B(X^0 \to \gamma\gamma)^2 < 20$ MeV for $m_{X^0} = 60 \pm 1$ GeV.

[166] ABREU 92D give $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to$ hadrons) < (3–10) pb for m_{X^0} = 10–78 GeV. A very similar limit is obtained for spin-1 X^0.

[167] ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z \cdot B(Z \to \gamma X^0)$ $B(X^0 \to$ hadrons) < (2–10) pb (95%CL) is given for m_{X^0} = 25–85 GeV.

[168] ACTON 91 searches for $Z \to Z^* X^0$, $Z^* \to e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.

[169] ACTON 91B limits are for m_{X^0} = 60–85 GeV.

[170] ADEVA 91D limits are for m_{X^0} = 30–89 GeV.

[171] ADEVA 91D limits are for m_{X^0} = 30–86 GeV.

[172] AKRAWY 90J give $\Gamma(Z \to \gamma X^0)\cdot B(X^0 \to$ hadrons) < 1.9 MeV (95%CL) for m_{X^0} = 32–80 GeV. We divide by $\Gamma(Z) = 2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \to \gamma q\overline{q}) < 8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to e^+e^-

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 55–61		[173] ODAKA	89	VNS	$\Gamma(X^0 \to e^+e^-)\cdot B(X^0 \to$ hadrons) $\gtrsim$ 0.2 MeV

>46.6	95	[175] ADEVA	85	MRKJ	$\Gamma(X^0 \to e^+e^-)$=10 keV
>48	95	[175] ADEVA	85	MRKJ	$\Gamma(X^0 \to e^+e^-)$=4 MeV
		[176] BERGER	85B	PLUT	
none 39.8–45.5		[177] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-)$=10 keV
>47.8	95	[177] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-)$=4 MeV
none 39.8–45.2		[177] BEHREND	84C	CELL	
>47	95	[177] BEHREND	84C	CELL	$\Gamma(X^0 \to e^+e^-)$=4 MeV

[173] ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \to$ hadrons at E_{cm} = 55.0–60.8 GeV.

[174] DERRICK 86 found no deviation from the Standard Model Bhabha scattering at E_{cm} = 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$-m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0, in which case the limit applies for $\Gamma(X^0 \to e^+e^-)$ = 3 MeV.

[175] ADEVA 85 first limit is from 2γ, $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. E_{cm} = 40–47 GeV. Supersedes ADEVA 84.

[176] BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \to e^+e^-$ and $\mu^+\mu^-$ at E_{cm} = 34.7 GeV. See Fig. 5 for excluded region in the m_{X^0} - $\Gamma(X^0)$ plane.

[177] ADEVA 84 and BEHREND 84C have E_{cm} = 39.8–45.5 GeV. MARK-J searched X^0 in e^+e^- → hadrons, 2γ, $\mu^+\mu^-$, e^+e^- and CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-)\cdot B(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0.

Searches for Axions (A^0) and Other Very Light Bosons

NOTE ON AXIONS

In this section we list limits for very light neutral (pseudo) scalar bosons that couple weakly to stable matter. Typical examples are pseudo-Goldstone bosons like axions (A^0) [1], familons [2], and Majorons [3], associated, respectively, with spontaneously broken Peccei-Quinn [4], family, and lepton-number symmetries.

Peccei-Quinn symmetry gives a natural solution to the strong CP-violation problem. Axion mass and its coupling to stable particles are inversely proportional to the scale of the Peccei-Quinn symmetry breaking f_A. The original axion model [1,4] assumes $f_A = v$, where $v = (\sqrt{2}G_F)^{-1/2} = 247$ GeV is the scale of the electroweak symmetry breaking, and has two Higgs doublets as minimal ingredients. By requiring tree-level flavor conservation, the axion mass and its couplings are completely fixed in terms of one parameter, the ratio of the vacuum expectation values of two Higgs fields. The result of extensive experimental searches for such an axion have been negative [5].

One way to avoid these experimental constraints is to make A^0 sufficiently massive. This is achieved by introducing a new strong interaction (QC′D) with $\Lambda_{QC'D} \gg \Lambda_{QCD}$, whose anomaly couples to the axion [7]. A^0 can receive significant mass from the QC′D sector if QC′D colored quarks are massive. However one needs an explanation why $|\theta_{QCD} - \theta_{QC'D}| < 10^{-9}$ in this scenario.

Another way to save the Peccei-Quinn idea is to introduce a new scale $f_A \gg v$. Then the A^0 mass becomes smaller and its coupling weaker, thus one can easily avoid all the existing experimental limits; such models are called invisible axion models [8,9]. Various invisible axion models can be

constructed by identifying f_A with other large mass scales such as the Planck mass, the GUT scale, the SUSY-breaking scale, and so on. It has been found, however, that invisible axions are not completely elusive. Cosmological considerations on the matter density of our universe suggest [10] $f_A < \mathcal{O}(10^{12})$ GeV as a possible upper bound on the scale. Lower bounds of $f_A > \mathcal{O}(10^7)$ GeV are obtained from astrophysics [11], where axion emission from the center of stellar objects can speed up their evolutionary time scales. The recent observation of the supernova SN1987A improves the lower bound to $f_A > \mathcal{O}(10^{10})$ GeV. Various terrestrial experiments to detect invisible axions by making use of their coupling to photons have been proposed [12], and the first result of such experiments appeared recently.

Observation of a narrow-peak structure in positron spectra from heavy ion collisions [13] suggested a particle of mass 1.8 MeV that decays into e^+e^-. Variants of the original axion model, which keep $f_A = v$, but drop the constraints of tree-level flavor conservation, were proposed [14]. Extensive searches for this particle, A^0(1.8 MeV), ended up with another negative result [6].

There is also a Note on invisible axions later in this section.

[3] ATIYA 93 looked for a peak in missing mass distribution. The limit is for massless stable A^0 particles and extends to m_{A^0}=80 MeV at the same level. See paper for dependence on finite lifetime.
[4] ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable A^0 of m_{A^0}=150–250 MeV, and the limit becomes stronger (10^{-8}) for m_{A^0}=180–240 MeV.
[5] NG 93 studied the production of X^0 via $\gamma\gamma \to \pi^0 \to \gamma X^0$ in the early universe at $T \sim 1$ MeV. The bound on extra neutrinos from nucleosyntheis $\Delta N_\nu < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0.
[6] ALLIEGRO 92 limit applies for m_{A^0}=150–340 MeV, and B($A^0 \to e^+e^-$)=100% assumed. Limit is $< 1.5 \times 10^{-8}$ at 99%CL.
[7] ATIYA 92 looked for a peak in missing mass distribution. The limit applies to m_{X^0}=0–130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires X^0 to be a vector particle.
[8] MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}$–10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained form m_{X^0} = 25–120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1.
[9] ATIYA 90B limit is for B($K^+ \to \pi^+ A^0$)·B($A^0 \to \gamma\gamma$) and applies for m_{A^0} = 50 MeV, $\tau_{A^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{A^0} < 100$ MeV, $\tau_{A^0} < 10^{-8}$ s.
[10] KORENCHENKO 87 limit assumes m_{A^0} = 1.7 MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and B($A^0 \to e^+e^-$) = 1.
[11] EICHLER 86 looked for $\pi^+ \to e^+ \nu A^0$ followed by $A^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of A^0. The quoted limits are valid when $\tau(A^0) \gtrsim 3. \times 10^{-10}$s if the decays are kinematically allowed.
[12] YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+$X. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

[13] ASANO 82 at KEK set limits for $B(K^+ \to \pi^+ A^0)$ for m_{A^0} <100 MeV as BR $< 4. \times 10^{-8}$ for $\tau(A^0 \to n\gamma\text{'s}) > 1. \times 10^{-9}$ s, BR $< 1.4 \times 10^{-6}$ for $\tau < 1. \times 10^{-9}$s.

[14] ASANO 81B is KEK experiment. Set $B(K^+ \to \pi^+ A^0) < 3.8 \times 10^{-8}$ at CL = 90%.

[15] ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ($3 < m < 40$ MeV) contradicts experimental muon anomalous magnetic moments.

A^0 (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

VALUE	CL%	EVTS	DOCUMENT ID		TECN	COMMENT

$<1.3 \times 10^{-3}$	90	0	[22] ALBRECHT	86D	ARG	$\Upsilon(1S) \to \gamma A^0$ $(A^0 \to e^+e^-, \gamma\gamma)$
$<2. \times 10^{-3}$	90		[23] BOWCOCK	86	CLEO	$\Upsilon(2S) \to \Upsilon(1S) \to A^0$
$<5. \times 10^{-3}$	90		[24] MAGERAS	86	CUSB	$\Upsilon(1S) \to A^0\gamma$
$<3. \times 10^{-4}$	90		[25] ALAM	83	CLEO	$\Upsilon(1S) \to A^0\gamma$
$<9.1 \times 10^{-4}$	90		[26] NICZYPORUK	83	LENA	$\Upsilon(1S) \to A^0\gamma$
$<1.4 \times 10^{-5}$	90		[27] EDWARDS	82	CBAL	$J/\psi \to A^0\gamma$
$<3.5 \times 10^{-4}$	90		[28] SIVERTZ	82	CUSB	$\Upsilon(1S) \to A^0\gamma$
$<1.2 \times 10^{-4}$	90		[28] SIVERTZ	82	CUSB	$\Upsilon(3S) \to A^0\gamma$

[16] The combined limit of ANTREASYAN 90C and EDWARDS 82 excludes standard axion with $m_{A^0} < 2m_e$ at 90% CL as long as $C_\Upsilon C_{J/\psi} > 0.09$, where C_V ($V = \Upsilon, J/\psi$) is the reduction factor for $\Gamma(V \to A^0\gamma)$ due to QCD and/or relativistic corrections. The same data excludes $0.02 < x < 260$ (90% CL) if $C_\Upsilon = C_{J/\psi} = 0.5$, and further combining with ALBRECHT 86D result excludes $5 \times 10^{-5} < x < 260$. x is the ratio of the vacuum expectation values of the two Higgs fields. These limits use conventional assumption $\Gamma(A^0 \to ee) \propto x^{-2}$. The alternative assumption $\Gamma(A^0 \to ee) \propto x^2$ gives a somewhat different excluded region $0.00075 < x < 44$.

[17] The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[18] The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[19] The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7 \times 10^{-12}$ s/MeV and $m_{A^0} < 200$ MeV.

[20] $\tau_{A^0} < 1 \times 10^{-13}$s and $m_{A^0} < 1.5$ GeV. Applies for $A^0 \to \gamma\gamma$ when $m_{A^0} < 100$ MeV.

[21] $\tau_{A^0} > 1 \times 10^{-7}$s.

[22] Independent of τ_{A^0}.

[23] BOWCOCK 86 looked for A^0 that decays into e^+e^- in the cascade decay $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^-$ followed by $\Upsilon(1S) \to A^0\gamma$. The limit for $B(\Upsilon(1S) \to A^0\gamma)B(A^0 \to e^+e^-)$ depends on m_{A^0} and τ_{A^0}. The quoted limit for m_{A^0}=1.8 MeV is at $\tau_{A^0} \sim 2. \times 10^{-12}$s, where the limit is the worst. The same limit $2. \times 10^{-3}$ applies for all lifetimes for masses $2m_e < m_{A^0} < 2m_\mu$ when the results of this experiment are combined with the results of ALAM 83.

[24] MAGERAS 86 looked for $\Upsilon(1S) \to \gamma A^0$ ($A^0 \to e^+e^-$). The quoted branching fraction limit is for $m_{A^0} = 1.7$ MeV, at $\tau(A^0) \sim 4. \times 10^{-13}$s where the limit is the worst.

[25] ALAM 83 is at CESR. This limit combined with limit for $B(J/\psi \to A^0\gamma)$ (EDWARDS 82) excludes standard axion.

[26] NICZYPORUK 83 is DESY-DORIS experiment. This limit together with lower limit 9.2×10^{-4} of $B(\Upsilon \to A^0\gamma)$ derived from $B(J/\psi(1S) \to A^0\gamma)$ limit (EDWARDS 82) excludes standard axion.

[27] EDWARDS 82 looked for $J/\psi \to \gamma A^0$ decays by looking for events with a single γ [of energy $\sim 1/2$ the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

[28] SIVERTZ 82 is CESR experiment. Looked for $\Upsilon \to \gamma A^0$, A^0 undetected. Limit for 1S (3S) is valid for $m_{A^0} < 7$ GeV (4 GeV).

A^0 (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<2.8 \times 10^{-5}$	90	[29] AKOPYAN	91	CNTR	o-Ps $\to A^0\gamma$ $(A^0 \to \gamma\gamma)$, $m_{A^0} < 30$ keV
$<1.1 \times 10^{-6}$	90	[30] ASAI	91	CNTR	o-Ps $\to A^0\gamma$, $m_{A^0} < 800$ keV
$<3.8 \times 10^{-4}$	90	GNINENKO	90	CNTR	o-Ps $\to A^0\gamma$, $m_{A^0} <$ 30 keV
$<(1\text{–}5) \times 10^{-4}$	95	[31] TSUCHIAKI	90	CNTR	o-Ps $\to A^0\gamma$, $m_{A^0} =$ 300–900 keV
$<6.4 \times 10^{-5}$	90	[32] ORITO	89	CNTR	o-Ps $\to A^0\gamma$, $m_{A^0} < 30$ keV
		[33] AMALDI	85	CNTR	Ortho-positronium
		[34] CARBONI	83	CNTR	Ortho-positronium

[29] The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0} < 10^{-13}\ m_{A^0}$ [keV] s.

[30] ASAI 91 limit translates to $g^2_{A^0e^+e^-}/4\pi < 1.1 \times 10^{-11}$ (90%CL) for $m_{A^0} < 800$ keV.

[31] The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[32] ORITO 89 limit translates to $g^2_{A^0ee}/4\pi < 6.2 \times 10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0}: $B < 7.6 \times 10^{-6}$ at 100 keV.

[33] AMALDI 85 set limits $B(A^0\gamma) / B(\gamma\gamma\gamma) < (1\text{–}5) \times 10^{-6}$ for $m_{A^0} = 900\text{–}100$ keV which are about 1/10 of the CARBONI 83 limits.

[34] CARBONI 83 looked for orthopositronium $\to A^0\gamma$. Set limit for A^0 electron coupling squared, $g(eeA^0)^2/(4\pi) < 6. \times 10^{-10}\text{–}7. \times 10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g-2$ experiments.

A^0 (Axion) Search in Photoproduction

Gauge & Higgs Boson Full Listings

Axions (A^0) and Other Very Light Bosons

[36] BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0. See Fig. 5 for the excluded region in m_{A^0}-x plane. For the standard axion, $0.3 < x < 25$ is excluded at 95% CL. If combined with BLUEMLEIN 91, $0.008 < x < 32$ is excluded.

[37] MEIJERDREES 92 give $\Gamma(\pi^- p \to n A^0)\cdot B(A^0 \to e^+e^-)/\Gamma(\pi^- p \to \text{all}) < 10^{-5}$ (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11}$–10^{-23} sec. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for $m_{A^0} = 25$–136 MeV.

[38] BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \to e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0}-x plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most $x > 1$, 0.2–11 MeV for most $x < 1$.

[39] FAISSNER 89 searched for $A^0 \to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$–20 MeV is excluded. Lower limit on f_{A^0} of $\simeq 10^4$ GeV is given for $m_{A^0} = 2m_e$–20 MeV.

[40] DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass ~ 1.1, ~ 2.1, and ~ 9 MeV, lifetimes 10^{-16}–10^{-15} s decaying to e^+e^- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.

[41] EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 ± 0.59 MeV, lifetime $(0.15 \pm 0.01) \times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at ~ 4 GeV/c/nucleon.

[42] FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma\gamma$. A standard axion decaying to 2γ is excluded except for a region $x \simeq 1$. Lower limit on f_{A^0} of 10^2–10^3 GeV is given for $m_{A^0} = 0.1$–1 MeV.

[43] BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range $m_{A^0} = (20$–$200)$ MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$-m_{A^0} plane.

[44] BERGSMA 85 look for $A^0 \to 2\gamma$, e^+e^-, $\mu^+\mu^-$. First limit above is for $m_{A^0} = 1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on f_{A^0}–m_{A^0} plane, where f_{A^0} is A^0 decay constant. For Peccei-Quinn PECCEI 77 A^0, $m_{A^0} < 180$ keV and $\tau > 0.037$ s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.

[45] FAISSNER 83 observed 19 1-γ and 12 2-γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

[46] FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ's are not at variance with LAMPF upper limit of 450 γ's. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega$ at $90^\circ] m_{A^0}/\tau_{A^0} < 14 \times 10^{-35}$ cm^2 sr^{-1} MeV ms^{-1}. See comment on FRANK 83B.

[47] FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ's. See comment on FAISSNER 83B.

[48] HOFFMAN 83 set CL = 90% limit $d\sigma/dt\, B(e^+e^-) < 3.5 \times 10^{-32}$ cm^2/GeV^2 for $140 < m_{A^0} < 160$ MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

[49] FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay region.

[50] FAISSNER 81 see excess μe events. Suggest axion interactions.

[51] FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 ± 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with η-A^0 mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82, CAVAIGNAC 83, and ANANEV 85.

[52] KIM 81 analyzed 8 candidates for $A^0 \to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86 \sim 5.6) \times 10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

[53] FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \to e^+e^-$ decay. Assuming $A^0/\pi^0 = 5.5 \times 10^{-7}$, obtained decay rate limit $20/(A^0$ mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.

[54] JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interactaction}) < 7. \times 10^{-68}$ cm^4, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ's or e^+e^-, and for axion mass a few MeV.

[55] SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

[56] BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^-. No signal found. CL = 90% limits for model parameter(s) are given.

[57] COTEUS 79 is a beam dump experiment at BNL.

[58] DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.

[59] BELLOTTI 78 first value comes from search for $A^0 \to e^+e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value$\times$(mass^{-4}). Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67}$ cm^4.

[60] BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67}$ cm^4.

[61] DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

[62] MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).

[63] VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A^0 (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[64] KETOV	86	SPEC	Reactor, $A^0 \to \gamma\gamma$
	[65] KOCH	86	SPEC	Reactor; $A^0 \to \gamma\gamma$
	[66] DATAR	82	CNTR	Light water reactor
	[67] VUILLEUMIER	81	CNTR	Reactor, $A^0 \to 2\gamma$

[64] KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 $[100 \text{ keV}/m_{A^0}]^6 \times 10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0} > 150$ keV. Not valid for $m_{A^0} \gtrsim 1$ MeV.

[65] KOCH 86 searched for $A^0 \to \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$ keV.

[66] DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture ($np \to d A^0$) at Tarapur 500 MW reactor. Sensitive to sum of $I = 0$ and $I = 1$ amplitudes. With ZEHNDER 81 $[(I = 0) - (I = 1)]$ result, assert nonexistence of standard A^0.

[67] VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0} < 280$ keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions

Limits are for branching ratio.

			[86] CALAPRICE	79		Carbon

[68] MINOWA 93 studied chain process, ^{139}Ce $\to$ ^{139}La* by electron capture and M1 transition of ^{139}La* to the ground state. It does not assume decay modes of A^0. The bound applies for $m_{A^0} < 166$ keV.

[69] HICKS 92 bound is applicable for $\tau_{X^0} < 4 \times 10^{-11}$ sec.

[70] The ASANUMA 90 limit is for the branching fraction of X^0 emission per ^{241}Am α decay and valid for $\tau_{X^0} < 3 \times 10^{-11}$ s.

[71] The DEBOER 90 limit is for the branching ratio ^{8}Be* (18.15 MeV, 1^+) $\to$ ^{8}Be A^0, $A^0 \to e^+e^-$ for the mass range $m_{A^0} = 4$–15 MeV.

[72] The BINI 89 limit is for the branching fraction of ^{16}O* (6.05 MeV, 0^+) $\to$ ^{16}O X^0, $X^0 \to e^+e^-$ for $m_X = 1.5$–3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of X is restricted to 0^+ or 1^-.

[73] AVIGNONE 88 looked for the 1115 keV transition C* $\to$ Cu A^0, either from $A^0 \to 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

[74] DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \to e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13}–10^{-8} s. The above limit is for $\tau = 5 \times 10^{-13}$ s and $m = 1.7$ MeV; see the paper for the τ-m dependence of the limit.

[75] The limit is for the branching fraction of $^{16}O^*(6.05\ MeV, 0^+) \rightarrow {}^{16}O X^0$, $X^0 \rightarrow e^+e^-$ against internal pair conversion for $m_{X^0} = 1.7$ MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for $m_{X^0} = 1.3$–3.2 MeV. The spin parity of X^0 must be either 0^+ or 1^-. The limit at 1.7 MeV is translated into a limit for the X^0-nucleon coupling constant: $g^2_{X^0NN}/4\pi < 2.3 \times 10^{-9}$.

[76] The DOEHNER 88 limit is for $m_{A^0} = 1.7$ MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than 10^{-4} are obtained for $m_{A^0} = 1.2$–2.2 MeV.

[77] SAVAGE 88 looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N, 17.64 MeV state $J^P = 1^+$ in ^8Be, and the 18.15 MeV state $J^P = 1^+$ in ^8Be. This experiment constrains the isovector coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \rightarrow 2.2)$ MeV and the isoscalar coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \rightarrow 2.6)$ MeV. Both limits are valid only if $\tau(A^0) \lesssim 1 \times 10^{-11}$ s.

[78] Limits are for $\Gamma(A^0(1.8\ MeV))/\Gamma(\pi M1)$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0} < 2 \times 10^{-11}$s. ^6Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCEI 86 model II and III.

[79] SAVAGE 86B looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N. Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1. \times 10^{-11}$s for $m_{A^0} = (1.1$–$1.7)$ MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.

[80] ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.

[81] CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}Nb^*decay}$ and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).

[82] ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges $m_{A^0} < 400$ keV (Li* decay) and 330 keV $< m_{A^0} < 2.2$ MeV. (deuteron* decay).

[83] LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5}$/s (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.

[84] ZEHNDER 82 used Goesgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0. Set limit $m_{A^0} < 60$ keV for any A^0.

[85] ZEHNDER 81 looked for $Ba^* \rightarrow A^0 Ba$ transition with $A^0 \rightarrow 2\gamma$. Obtained 2γ coincidence rate $< 2.2 \times 10^{-5}$/s (CL = 95%) excluding $m_{A^0} > 160$ keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.

[86] CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A^0 (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \rightarrow e^+e^-)$.

VALUE (s)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •

none 3×10^{-13}–1×10^{-7}	90	[94] KONAKA	86	BDMP	$eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)

[87] The listed BROSS 91 limit is for $m_{A^0} = 1.14$ MeV. $B(A^0 \rightarrow e^+e^-) = 1$ assumed. Excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron $g-2$ constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} < 4.8$ MeV (90%CL).

[88] GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with $g-2$ constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).

[89] BJORKEN 88 reports limits on axion parameters (f_A, m_A, τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.

[90] BLINOV 88 assume zero spin, $m = 1.8$ MeV and lifetime $< 5 \times 10^{-12}$ s and find $\Gamma(A^0 \rightarrow \gamma\gamma)B(A^0 \rightarrow e^+e^-) < 2$ eV (CL=90%).

[91] Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.

[92] Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.

[93] $m_{A^0} = 1.8$ MeV assumed. The excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.

[94] The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$–$A^0e^+e^-$ coupling plane by assuming Primakoff production.

Search for A^0 (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$.

[95] HALLIN 92 quote limits on lifetime, $8 \times 10^{-14} - 5 \times 10^{-13}$ sec depending on mass, assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

[96] HENDERSON 92C exclude axion with lifetime $\tau_{A^0} = 1.4 \times 10^{-12} - 4.0 \times 10^{-10}$ s, assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. HENDERSON 92C also exclude a vector boson with $\tau = 1.4 \times 10^{-12} - 6.0 \times 10^{-10}$ s.

[97] WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.

[98] WIDMANN 91 bound applies exclusively to the case $B(A^0 \rightarrow e^+e^-) = 1$, since the detection efficiency varies substantially as $\Gamma(A^0)_{total}$ changes. See their Fig. 6.

[99] JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s $< \tau(A^0) < 7.5 \times 10^{-12}$ s (95% CL) at $m_{A^0} = 1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776$–1.856 MeV.

[100] See also TSERTOS 88B in references.

[101] The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.

[102] VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$–10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.

[103] MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{cm} \simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma^2_{ee}/\Gamma_{total}$. For a discussion implying that $\Delta E_{cm} \simeq 10$ keV, see TSERTOS 89.

[104] VONWIMMERSPERG 87 measured Bhabha scattering for $E_{cm} = 1.37$–1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{cm} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

Search for A^0 (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for $\Gamma(A^0 \rightarrow e^+e^-)\cdot\Gamma(A^0 \rightarrow \gamma\gamma)/\Gamma_{total}$

[109] BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2 \times 10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.

[110] ALBRECHT 90E limits are for $B(\tau \to \ell X^0)/B(\tau \to \ell \nu \bar{\nu})$. Valid for $m_{X^0} < 100$ MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for $m_{X^0} = 500$ MeV.

[111] ATIYA 90 limit is for $m_{X^0} = 0$. The limit $B < 1 \times 10^{-8}$ holds for $m_{X^0} < 95$ MeV. For the reduction of the limit due to finite lifetime of X^0, see their Fig. 3.

[112] BOLTON 88 limit corresponds to $F > 3.1 \times 10^9$ GeV, which does not depend on the chirality property of the coupling.

[113] CHANDA 88 find $v_T < 10$ MeV for the weak-triplet Higgs vev. in Gelmini-Roncadelli model, and $v_S > 5.8 \times 10^6$ GeV in the singlet Majoron model.

[114] CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2 \times 10^{-5} < h < 3 \times 10^{-4}$ for the interaction $L_{\rm int} = \frac{1}{2} i h \bar{\psi}_\nu^c \gamma_5 \psi_\nu \phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^4)^{1/4}$.

[115] PICCIOTTO 88 limit applies when $m_{X^0} < 55$ MeV and $\tau_{X^0} > 2$ns, and it decreases to 4×10^{-7} at $m_{X^0} = 125$ MeV, beyond which no limit is obtained.

[116] GOLDMAN 87 limit corresponds to $F > 2.9 \times 10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int} = (1/F)\bar{\psi}_\mu \gamma^\mu (a + b\gamma_5) \psi_e \partial_\mu \phi_{X^0}$ with $a^2 + b^2 = 1$. This is not as sensitive as the limit $F > 9.9 \times 10^9$ GeV derived from the search for $\mu^+ \to e^+ X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.

[117] Limits are for $\Gamma(\mu \to e X^0)/\Gamma(\mu \to e \nu \bar{\nu})$. Valid when $m_{X^0} = 0$–93.4, 98.1–103.5 MeV.

[118] EICHLER 86 looked for $\mu^+ \to e^+ X^0$ followed by $X^0 \to e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0. The quoted limits are valid when $\tau_{X^0} \lesssim 3. \times 10^{-10}$ s if the decays are kinematically allowed.

[119] JODIDIO 86 corresponds to $F > 9.9 \times 10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int} = (1/F)\, \bar{\psi}_\mu \gamma^\mu \psi_e \partial^\mu \phi_{X^0}$.

[120] BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95% limits are $B(\tau \to \mu^+ X^0)/B(\tau \to \mu^+ \nu\nu) < 0.125$ and $B(\tau \to e^+ X^0)/B(\tau \to e^+ \nu\nu) < 0.04$. Inferred limit for the symmetry breaking scale is $m > 3000$ TeV.

[121] The primordial heavy neutrino must decay into ν and familon, f_A, early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \pi f_A$ and $\mu \to e f_A$ are unseen. Combining these excludes $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 5×10^{-4} MeV (μ decay) and $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. Previous indications for neutrinoless double beta decay with majoron emission have been superseded. No experiment currently claims any such evidence. For a review, see DOI 88.

[122] BERNATOWICZ 92 studied double-β decays of ^{128}Te and ^{130}Te, and found the ratio $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of ^{128}Te of $(7.7 \pm 0.4) \times 10^{24}$ year. We calculated 90% CL limit as $(7.7\text{–}1.28 \times 0.4\text{=}7.2) \times 10^{24}$.

[123] TANAKA 93 also quote limit 5.3×10^{19} years on two Majoron emission.

[124] VERGADOS 82 sets limit $g_H < 4 \times 10^{-3}$ for (dimensionless) lepton-number violating coupling, g_H, of scalar boson (Majoron) to neutrinos, from analysis of data on double β decay of ^{48}Ca.

INVISIBLE A^0 (AXION) MASS LIMITS FROM ASTROPHYSICS AND COSMOLOGY

Limits on $m(A^0)$ are obtained from the axion coupling to electrons, nucleons, or photons. Quoted limits are often expressed in terms of the axion decay constant f_A which can be defined in terms of the mass or axion-electron coupling by $m(A^0) = 3.5 \times 10^{10} g_{Ae} \cos^{-2}\beta\,\text{eV} = 7.2 \times 10^7 (\text{GeV}/f_A)(N/6)\,\text{eV}$ [using the conventions detailed in Srednicki [1]; for other conventions take $f_A \to 2f_A$ (Bardeen [2]) or $f_A \to 4f_A$ (Kaplan [3])] where N is the number of quarks with Peccei-Quinn charge (usually the number of quark flavors) and $\cos^2\beta = v_1^2/(v_1^2 + v_2^2)$ is determined by the vacuum expectation values of the two Higgs doublets coupling to up and down quarks (and charged leptons). For the coupling to photons $m(A^0) = 6.9 \times 10^9 (g_{A\gamma}/\text{GeV}^{-1})\,\text{eV}$ and for the coupling to nucleons $m(A^0) = 7.7 \times 10^7 g_{AN}/c_{AN}\,\text{eV}$ where c_{AN} depends on the details of the coupling of axions to nucleons. These couplings are defined by

$$\mathcal{L}_{\rm int} = -\frac{1}{4} g_{A_\gamma}\, \phi_A\, F_{\mu\nu}\, \tilde{F}^{\mu\nu} = g_{A_\gamma}\, \phi_A\, \mathbf{E} \cdot \mathbf{B}\ ,$$

$$\mathcal{L}_{\rm int} = i g_{Ae}\, \phi_A\, \overline{\psi}_e\, \gamma_5 \psi_e\ , \qquad \text{and}$$

$$\mathcal{L}_{\rm int} = i g_{AN}\, \phi_A\, \overline{\psi}_N\, \gamma_5\, \psi_N\ .$$

The factors in these equations are model dependent, in particular $g_{Ae} = 0$ in the KSVZ [4] models. In the comment for each limit below, D indicates that the limit is specific to DFSZ [5] axions, K to KSVZ axions (The limits quoted assume $N = 6$ and $v_1 = v_2$.)

[125] BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

[126] KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.

[127] RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.

[128] RESSELL 91 uses absence of any intracluster line emission to set limit.

[129] ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to 2.5×10^{-3} eV $\lesssim m_{A^0} \lesssim 2.5\times10^{4}$ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

[130] RAFFELT 90D is a re-analysis of DEARBORN 86.

[131] The region $m_{A^0} \gtrsim 2$ eV is also allowed.

[132] ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

[133] MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.

[134] RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100$ erg g^{-1} s^{-1}, which gives a firmer basis for the axion limits based on red giant cooling.

[135] RAFFELT 87 also gives a limit $g_{A\gamma} < 1\times10^{-10}$ GeV^{-1}.

[136] DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4\times10^{-11}$ GeV^{-1}.

[137] RAFFELT 86 gives a limit $g_{A\gamma} < 1.1\times10^{-10}$ GeV^{-1} from red giants and $< 2.4\times10^{-9}$ GeV^{-1} from the sun.

[138] KAPLAN 85 says $m_{A^0} < 23$ eV is allowed for a special choice of model parameters.

[139] FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3\times10^{-10}$ GeV^{-1}.

Search for Relic Invisible Axions

Limits are for $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\rm int} = \frac{G_{A\gamma\gamma}}{4}\phi_A F_{\mu\nu}\tilde{F}^{\mu\nu} = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$, and ρ_A is the axion energy density near the earth.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<2\times10^{-41}$		[140] HAGMANN	90	CNTR	m_{A^0} = (5.4–5.9)10^{-6} eV
$<1.3\times10^{-42}$	95	[141] WUENSCH	89	CNTR	m_{A^0} = (4.5–10.2)10^{-6} eV
$<2\times10^{-41}$	95	[141] WUENSCH	89	CNTR	m_{A^0} = (11.3–16.3)10^{-6} eV

[140] HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

[141] WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2\times10^{-14}$ MeV^{-4} (the three generation DFSZ model) and $\rho_A = 300$ MeV/cm^3 that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\,\rho_A = 4\times10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A^0 (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L = G_{A\gamma\gamma}\phi_A\mathbf{E}\cdot\mathbf{B}$.

Related limits from astrophysics can be found in the "Invisible A^0 (Axion) Mass Limits from Astrophysics and Cosmology" section.

[142] Experiment based on proposal by MAIANI 86.

[143] Experiment based on proposal by VANBIBBER 87.

[144] LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.

[145] RUOSO 92 experiment is based on the proposal by VANBIBBER 87.

[146] SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4\times10^{-3}$ where $G_{A\gamma\gamma} < 1\times10^{-4}$ GeV^{-1}.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for $G_{Aee}\partial_\mu\phi_A\bar{e}\gamma^\mu\gamma_5 e$ in GeV^{-1}, or equivalenty, the dipole-dipole potential $\frac{G^2_{Aee}}{4\pi}\left((\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1\cdot\boldsymbol{n})(\boldsymbol{\sigma}_2\cdot\boldsymbol{n})\right)/r^3$ where $\boldsymbol{n}=\boldsymbol{r}/r$.

The limits below apply to invisible axion of $m_A \le 10^{-6}$ eV.

$<8.9\times10^{-4}$	66	[149] RITTER	90		Torsion pendulum
$<6.4\times10^{-5}$	95	[147] VOROBYOV	88		Induced magnetism

[147] These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.

[148] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

[149] RITTER 90 used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them.

LEPTONS

NOTE ON NEUTRINOS

(by R.E. Shrock, State Univ. of New York, Stony Brook)

In addition to the ν_e, ν_μ, and ν_τ sections, the *Review of Particle Properties* includes sections on "Searches for Massive Neutrinos and Lepton Mixing," "Number of Light Neutrino Types," "Heavy Lepton Searches," and "Constraints from Cosmology and Astrophysics."

The theoretical perspective concerning neutrino masses has changed considerably over the past 20 years. Before that time, a standard view was that there was no theoretical reason for neutrinos to have masses, which was in accord with the striking fact that the upper limits on their masses were much smaller than those of the associated charged leptons. It was also noted that experimental data were consistent with the "laws" of lepton family number and total lepton number conservation. (Some early discussions of neutrino oscillations and lepton mixing are given in Refs. 1 and 2). Indeed, even in the literature of the 1970's, one will often find statements asserting that in the standard SU(2)× U(1) electroweak theory (without electroweak-singlet neutrinos) the known (electroweak-doublet) neutrinos are massless.

In contrast, in the modern theoretical view based on the standard electroweak theory (and its supersymmetric extensions which stabilize the hierarchy), small but nonzero neutrino masses are expected on general grounds. The reason for this is as follows. Given only the known left-handed neutrino fields and the usual Higgs field(s) in the Standard Model (and supersymmetric extensions thereof which stabilize the hierarchy), nonzero neutrino masses result generically from higher-dimension operators which are strongly expected to occur at a scale near to that of quantum gravity. This expectation is based on the general consensus that pointlike theories of quantum gravity are nonrenormalizable, and is borne out by explicit calculations of the low-energy, field-theory limit of string theories. Such higher-dimension operators would be suppressed by associated inverse powers of the (reduced) Planck mass, $\kappa^{-1} \equiv \overline{M}_P \equiv \sqrt{\hbar c/(8\pi G_N)} = 2.4 \times 10^{18}$ GeV. For example, there would be a gauge-invariant dimension-5 operator consisting of the weak $I = 1$, $Y = -2$ Majorana bilinear ${\nu_L}^T C \nu_L$ (where generation indices are suppressed) contracted with a symmetric, $I = 1$ quadratic product of the usual $I = 1/2$, $Y = 1$ Higgs, with a coefficient of the form $a/\overline{M}_P$, where a is a dimensionless constant. From the vacuum expectation values of the Higgs, this would give rise to (Majorana) neutrino masses of order $m_\nu \sim av^2/\overline{M}_P$, where $v = 250$ GeV is the scale of electroweak-symmetry breaking. (Here $\overline{M}_P$ is an approximate upper bound on the mass which suppresses such operators; it is possible that new physics occurs at some intermediate mass scale $v \ll M_I < \overline{M}_P$ in such a way that dimension-5 operators of this type would give rise to neutrino masses of order av^2/M_I.) This not only leads one to expect nonzero neutrino masses but explains why they are so small.

In retrospect, one sees that this change in theoretical perspective is associated with the change in viewpoint concerning quantum field theory. For decades after the success of quantum electrodynamics in the late 1940's, renormalizability was taken as a necessary property for an acceptable fundamental quantum field theory. It was this implicit theoretical assumption which led to the oft-repeated statements in the 1970's that in the standard electroweak theory (without electroweak-singlet neutrinos) the known neutrinos are massless. More recently, it has been appreciated that renormalizability and, in particular, the great success of the Standard Model with its exclusion of any higher-dimension nonrenormalizable operators, may well be due only to the fact that the electroweak scale v is much smaller than $\overline{M}_P$ (or possibly even some lower scale, M_I), *i.e.*, a consequence of the hierarchy. Once one includes such higher-dimension operators in one's considerations, the realization that neutrino masses are generic follows immediately. A summary of this modern view is given, *e.g.*, in Ref. 3.

In contrast to this mechanism for neutrino mass, which only relies upon the known neutrinos, together with the Higgs field(s) of the Standard Model (or its supersymmetric extensions), there is another more speculative mechanism which we mention here for completeness. It is not known whether there exist any electroweak-singlet neutrino fields. If they do exist, then they could lead, via renormalizable, dimension-4 operators, to neutrino masses $m_\nu \sim v^2/M_R$, where the scale M_R of the electroweak-singlet neutrino mass is naturally $\gg v$, again yielding, albeit for a different reason, very small m_ν [4].

In turn, a natural concomitant of (nondegenerate) neutrino masses is lepton mixing, which is thus also a general expectation. The lepton-mixing angles are functions of ratios of elements of neutrino-matrix elements and of charged lepton mass matrix elements, and even though left-handed neutrino masses are small, some of these ratios could, in principle, be $\mathcal{O}(1)$, which raises the issue of why such effects have not been seen. This question was answered as follows: a set of conditions for natural suppression of observable lepton flavor violation were formulated, and it was shown that the Standard Model (generalized to include nonzero m_ν) satisfies these [5]. This explains why the "law" of lepton family number conservation is obeyed to such high accuracy.

After these theoretical points, let us return to a description of the quantities upon which various experiments put limits. As an aid to understanding the limits on neutrino masses and lepton mixing, we recall that, in contrast to other particles in this *Review*, the neutrinos ν_e, ν_μ, and ν_τ are defined as weak eigenstates (the weak $I_3 = 1/2$ components of the $SU(2)_L$ lepton doublets) which couple with unit strength to e, μ, and τ, respectively. These neutrino weak eigenstates are not, in general, states of definite mass. If one assumes that neutrinos are massless, and hence degenerate, then it is possible to define the

weak eigenstates to be simultaneously mass eigenstates. However, in the general case of possibly massive (nondegenerate) neutrinos, the weak eigenstates have no well-defined masses, but instead are linear combinations of mass eigenstates. Let us denote the charged leptons as the set $\{\ell_a\}$, $a = 1, \ldots, n$, where $n \geq 3$, with $\ell_1 = e$, $\ell_2 = \mu$, and $\ell_3 = \tau$. From the LEP measurement of the Z width (see section on "Number of Light Neutrinos"), one knows that there are only three neutrinos which couple to the Z in the usual way and have masses $m_\nu < m_Z/2$. Of course, this measurement does not preclude the existence of electroweak-singlet neutrinos. The latter are often called "right-handed neutrino singlets," although, since they are singlets, it is a convention whether one chooses to write them as $(\chi_j)_R$ or $(\chi'_j)_L = (\chi^c_j)_L$. The left-handed components of the weak eigenstates of the neutrinos, $(\nu_{\ell_a})_L$ can be expressed in terms of mass eigenstates by the transformation

$$(\nu_{\ell_a})_L = \sum_j U_{aj} (\nu_j)_L \tag{1}$$

where the $\{\nu_j\}$ denote these mass eigenstates and consist of n members together with possible additional SU(2) × U(1) singlet neutral leptons, often called "sterile" neutrinos. The ordering of the mass eigenbasis can be defined so that U is as nearly diagonal as possible, *i.e.* (with no sum on j) $|U_{jj}| \geq |U_{jk}|$, $k \neq j$. Of course, this does not imply that $m_{\nu_j} > m_{\nu_k}$ for $j > k$.

Thus, as was noted in Ref. 6, decays such as $^3\mathrm{H} \to {}^3\mathrm{He}\, e^- \overline{\nu}_e$ and $\pi^+ \to \mu^+ \nu_\mu$, which have been used to set the best bounds on the respective neutrino masses, really consist of sums of the separate decay modes $^3\mathrm{H} \to {}^3\mathrm{He}\, e^- \overline{\nu}_j$ and $\pi^+ \to \mu^+ \nu_k$, where the ν_j and ν_k are mass eigenstates, and the indices j and k range over all of the values allowed by phase space in these respective decays. The coupling strengths for the j'th mode in $^3\mathrm{H}$ β decay and the k'th mode in $\pi^+_{\mu 2}$ decay are given, respectively, by $|U_{1j}|^2$ and $|U_{2k}|^2$. In general, these modes are incoherent, although in the limit in which the ν_j all become degenerate they would become coherent. There are, in addition certain kinematic factors depending on the m_{ν_j} which enter in determining the branching ratio for a given decay mode. Assuming that the off-diagonal elements of the lepton mixing matrix U are small relative to the diagonal elements, the dominantly coupled decays are the ones with coupling strength $|U_{aj}|^2$, $a = j$, *i.e.*, $^3\mathrm{H} \to {}^3\mathrm{He}\, e^- \overline{\nu}_1$ and $\pi^+ \to \mu^+ \nu_2$.

Hence, it follows that the neutrino mass limits quoted in the literature for "m_{ν_e}," "m_{ν_μ}," and "m_{ν_τ}" should really be interpreted as limits on the corresponding mass eigenstates [6,7]. Specifically, a bound on "m_{ν_e}" from a study of tritium β decay, for example, really constitutes a weighted limit on each of the mass eigenstates ν_j in the weak eigenstate ν_e which are kinematically allowed to occur in tritium decay and which are coupled with strength $|U_{1j}|^2$ sufficiently large to make a significant contribution to the observed spectrum. It is thus certainly a limit on ν_1, since this is, by the definition, of the order of the mass eigenbasis, the dominantly coupled neutrino. If lepton mixing is hierarchical, as quark mixing is known to be, *i.e.*, if $|U_{jj}|^2 \gg |U_{jk}|^2$, $j \neq k$, then ν_1 is the only mass eigenstate significantly constrained by a bound on "m_{ν_e}." Furthermore, strictly speaking, a neutrino mass limit cannot be stated in isolation; it always contains some implicit dependence on the relevant lepton-mixing angles. This dependence is fortunately relatively unimportant for the dominantly coupled decay modes, *i.e.*, $e\,\overline{\nu}_1$, $\mu\,\overline{\nu}_2$, and $\tau\,\overline{\nu}_3$ and hence the mass limits on "m_{ν_e}," "m_{ν_μ}," and "m_{ν_τ}" can be reinterpreted as being limits on m_{ν_j}, $j = 1$, 2, and 3, respectively.

There are three general types of (Lorentz-invariant) neutrino mass terms: Dirac masses of the form $m_D\,\overline{\nu}_L\,\chi_R + h.c.$, left-handed Majorana masses of the form $m_L\,\overline{\nu}_L\,\nu^c_R + h.c. = m^*_L\,{\nu_L}^T\,C\nu_L + h.c.$ and right-handed Majorana masses of the form $m_R\,\overline{\chi}^c_L\,\chi_R + h.c. = m_R\,\chi_R^T C\,\chi_R + h.c.$, where C is the Dirac charge conjugation matrix. Dirac mass terms conserve total lepton number $L_{\rm tot}$, while Majorana mass terms violate $L_{\rm tot}$. In the standard electroweak theory, extended to include massive neutrinos, (i) a Dirac mass term transforms as a weak $I = 1/2$ operator, and is coupled to the $I = 1/2$ Higgs to make an SU(2) × U(1) singlet operator; (ii) a Majorana mass term involving the $I = 1/2$ left-handed neutrinos transforms as $I = 1$ and must be coupled to an operator with $I = 1$ (and $Y = 2$) to make a gauge-invariant singlet; (iii) a Majorana-mass term involving the SU(2) × U(1) singlet neutral leptons, conventionally considered to be right-handed, is a singlet; it could be present as a bare mass term or couple to some other singlet operator. Note that in the minimal supersymmetric standard model (MSSM), which has two Higgs doublets, of hypercharge $Y = 1$ and $Y = -1$, the Dirac neutrino mass term arises from the cubic chiral superfield coupling $\epsilon_{ij}\widehat{L}^i\widehat{\chi}^c\widehat{H}^j_u$ (all chiral superfields are taken as left-handed), where $\widehat{H}_u$ is the same Higgs that gives mass to the $Q = 2/3$ quarks. The Dirac neutrino mass terms are thus proportional to $\sin\beta$, where $\tan\beta = v_u/v_d$ is the ratio of the vacuum expectation values of the two Higgs in the MSSM.

In general, in the Standard Model, in addition to the three known left-handed $I = 1/2$ lepton doublets, there could be some number n_s of electroweak-singlet neutrinos. In a compact notation, one can then denote ν_L as the 3-component vector of left-handed $I = 1/2$ neutrinos and χ_R to be the n_s-dimensional vector of electroweak-singlet singlets, taken to be right-handed. In supersymmetric extensions of the Standard Model, the χ_R arise as (conjugates of) the spin 1/2 component fields in (left-handed) gauge-singlet chiral superfields. The general neutrino mass term in the Lagrangian is then given by

$$-\mathcal{L}_m = \frac{1}{2}(\overline{\nu}_L, \overline{\chi}^c_L) \begin{pmatrix} M_L & M_D \\ M_D^T & M_R \end{pmatrix} \begin{pmatrix} \nu^c_R \\ \chi_R \end{pmatrix} + h.c. \tag{2}$$

where M_L is the 3×3 left-handed Majorana-mass matrix, M_R is a $n_s \times n_s$ right-handed Majorana-mass matrix, and M_D is the 3-row by n_s-column Dirac-mass matrix. In general, all of these mass matrices are complex. The anticommutativity of fermion fields and the property that $C\gamma_\mu C^{-1} = -{\gamma_\mu}^T$

together imply that the Majorana mass matrices are symmetric: $M_L = M_L{}^T, M_R = M_R{}^T$. The diagonalization of the full $(3+n_s)\times(3+n_s)$ mass matrix in Eq. (2) yields $3+n_s$ mass eigenstates, which are, in general, of Majorana type. Since Majorana mass terms violate total lepton number, one sees from a general viewpoint that one does not expect conservation of total lepton number. In particular, the dimension-5 operators discussed above give rise to left-handed Majorana neutrino mass terms and violate total lepton number. Dirac-neutrinos can be constructed from two Majorana-neutrino mass eigenstates whose masses are equal in magnitude [8]. For this reason, Dirac neutrino masses may be considered to be a special (degenerate) case of Majorana neutrino masses, and the latter may be regarded as the generic case. From the similarity transformation which diagonalizes the neutrino mass matrix, together with the similarity transformation which diagonalizes the charged lepton mass matrix (where, of course, only Dirac masses are allowed by electric-charge conservation), one constructs the lepton-mixing matrix U. In general, since U is not the identity, neutrino masses naturally give rise to lepton family number violation.

In supersymmetric extensions of the Standard Model, the neutrinos could, *a priori*, mix with the neutralinos (higgsinos and neutral gauginos). However, the usual R parity which is invoked to forbid unacceptably rapid proton decay also prevents such mixing between neutrinos and neutralinos.

In addition to mass and lifetime limits, this *Review* includes limits on various other possible properties, including electric charge, the *CPT*-violating difference $m_{\nu_1} - m_{\overline{\nu}_1}$, and a magnetic dipole moment. These are of interest because a massless purely chiral Dirac neutrino cannot have a magnetic (or electric) dipole moment. In the standard electroweak theory, extended to allow for Dirac neutrino masses, the neutrino magnetic dipole moment is nonzero and given [5,9], as

$$\mu_{\nu_j} = \frac{3eG_F m_{\nu_j}}{8\pi^2\sqrt{2}} = 3.2\times10^{-19}(m_{\nu_j}/1\text{ eV})\mu_B \qquad (3)$$

where G_F is the Fermi constant and $\mu_B = e/2m_e$ is the Bohr magneton. The neutrino electric dipole moment violates both time-reversal invariance and parity; although it is nonzero in general, it is quite small (see, *e.g.* Ref. 10). Again, however, we note that Dirac neutrinos should be regarded as a special case; the generic case is Majorana neutrinos. The operator products which define the magnetic and electric-dipole moments, *viz.*, $\overline{\nu}\,\sigma_{\alpha\beta}\,\nu\,F^{\alpha\beta}$ and $\overline{\nu}\,\sigma_{\alpha\beta}\,\gamma_5\,\nu\,F^{\alpha\beta}$, respectively (where $F^{\alpha\beta}$ is the electromagnetic field strength tensor) vanish identically if ν is a Majorana neutrino because of the Majorana property that $\nu^c = \pm\nu$. Thus, a Majorana neutrino has identically zero magnetic and electric dipole moments.

Only the diagonal magnetic- and electric-dipole moments are static properties of a given neutrino-mass eigenstate. Transition magnetic and electric dipole moments exist in general for both Dirac and Majorana neutrinos but are not static properties and hence are not considered here. Occasionally, one also finds references to the "neutrino charge radius" in the literature. This is defined via the Taylor series expansion of the generalized vector Dirac form factor multiplying γ_μ in the electromagnetic current matrix element: $F_1^V(q^2) = F_1^V(0) + q^2\,dF_1^V/dq^2|_{q^2=0} + \mathcal{O}[(q^2)^2]$, where q denotes the 4-momentum of the photon [see, *e.g.* Ref. 5 Eq. (2.20)]. The electric charge is $Q = F^V(0) = 0$ for a neutrino, and the charge radius is given by $\langle r^2\rangle = (1/6)(F_1^V)'(0)$. However, since this is multiplied by q^2 in the Taylor series expansion, it never occurs for a real photon, where $q^2 = 0$, and hence is not an S-matrix element, *i.e.*, not a physical quantity. In a gauge theory, this is manifested in the fact that the charge radius is gauge-dependent.

If one considers the possibility of nonzero masses for neutrinos, for consistency one must then also consider the leptonic mixing which would in general occur concomitantly. Accordingly, this *Review* devotes a section to correlated bounds on neutrino masses and lepton mixing angles. These can be divided into two types. First, there are those due to decays involving neutrinos in the final state, which must be recognized to have the possible multimode structure pointed out above. In the two most sensitive cases suggested as tests for neutrino masses and mixing, one obtains a limit on m_{ν_j} and $|U_{aj}|^2$ individually for each j. The peak-search test proposed in Ref. 6 was applied to existing data in that paper and a subsequent one [7]; it was applied in new experiments on 2-body leptonic decays of K^+ and π^+ by several groups at SIN (PSI), KEK, and TRIUMF. The results are catalogued in corresponding subsections on limits on $|U_{1j}|^2$ and $|U_{2j}|^2$. The kink-search test was also applied by a number of groups. The experimental situation, which was controversial for many years, has recently been clarified (see below).

Second, there are those due to processes involving the propagation and subsequent interaction of neutrinos. The latter are often called neutrino-oscillation limits, although this term is strictly correct only if the differences in neutrino masses are sufficiently small relative to their momenta that the propagation is effectively coherent in a quantum mechanical sense; otherwise, the individual ν_j from a given decay such as $\pi_{\mu 2}$ or $K_{\mu 2}$ propagate in a measurably incoherent manner, and there is no oscillation. Experimentalists usually present their results in terms of a simplifying model in which mixing is assumed to occur only between two neutrino species. The relevant transformation equation becomes

$$\begin{pmatrix}\nu_{\ell_a}\\ \nu_{\ell_b}\end{pmatrix} = \begin{pmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{pmatrix}\begin{pmatrix}\nu_i\\ \nu_j\end{pmatrix} \qquad (4)$$

where ν_{ℓ_a} are the weak-neutrino eigenstates, with $\nu_{\ell_1} = \nu_e$, *etc.*, and ν_i are neutrino mass eigenstates. Let the distance between the source of the neutrinos and their point of interaction be denoted L, and their energy as E. Assume furthermore that the m_{ν_i} are such that the coherence assumption is valid. Then the probability of an initial ν_{ℓ_a}, having propagated for a distance $t = L$ (with $1 - v/c \ll 1$) being equal to ν_{ℓ_b} is given by

$$P \equiv |\langle\nu_{\ell_b}|\nu_{\ell_a}(t)\rangle|^2 = \sin^2 2\theta\sin^2\left(\frac{\Delta m^2 L}{4E}\right) \qquad (5)$$

where

$$\Delta m^2 = m^2_{\nu_i} - m^2_{\nu_j} \ . \tag{6}$$

Thus, neutrino-oscillation experiments cannot measure individual neutrino masses, but only differences of masses squared, and indeed these are generally weighted in a more complicated way by lepton-mixing matrix coefficients for the general case where there is mixing among more than just two species. Experimental results are presented as allowed regions on a plot, the axes of which are $|\Delta m^2|$ and $\sin^2 2\theta$. These are often summarized in terms of the upper limit on Δm^2 (the absolute value is usually suppressed in the notation) for maximal mixing, $\sin^2 2\theta = 1$, and the upper limit on $\sin^2 2\theta$ for "large" Δm^2, *i.e.*, sufficiently large $|\Delta m^2|$ that the detector averages over many cycles of oscillation (or there ceases to be any coherence). A more complete discussion is given in the "Note on Neutrino Oscillation Experiments" just before the tables reporting such results.

An important type of experiment is the search for neutrinoless double-β decay, which tests for total lepton number violation such as would result for Majorana-neutrino masses. This process takes place when a nucleus with Z protons and $A = ZN$ nucleons decays according to $(Z, A) \rightarrow (Z+2, A)e^-e^-$, violating total lepton number by two units. In the case of neutrinos with masses which are sufficiently light, an upper limit on neutrinoless double-β decay yields a correlated upper limit on the quantity

$$\overline{m} = \left| \sum_j U^2_{1j} m_{\nu_j} \right| \ . \tag{7}$$

Cancellations may occur in the sum, since U_{1j} is, in general, complex. See Ref. 11 for some recent reviews of searches for neutrinoless double-β decay.

A brief summary of the current experimental situation follows (see previous editions for discussions of various positive claims for neutrino masses and mixing, and their refutations).

1. There is no evidence at present from direct searches for nonzero neutrino masses. These include the endpoint of the Kurie plot in nuclear-β decay for m_{ν_e}, $\pi^+ \rightarrow \mu^+\nu_\mu$ for m_{ν_μ}, and certain τ decays for m_{ν_τ} (where, as discussed above, the limits actually apply to the respective mass eigenstates ν_1, ν_2, and ν_3 in these three weak eigenstates). There has been some concern over the fact that the quantity which is actually measured, *i.e.*, the square of the neutrino mass, is negative by several standard deviations for ν_e. This may indicate systematic errors in the measurements which are not understood. A similar situation was noticed recently for the muon neutrino mass squared. Although there is still no resolution of this in the refereed journal literature, it has been argued [12,13] that the reason for this is that the charged-pion mass has been determined incorrectly from pionic x-rays, that this determination is actually ambiguous(!), and that when the analysis is interpreted differently, the charged pion mass is increased so as to yield a measurement of $m^2_{\nu_\mu}$ ($m^2_{\nu_2}$) which is no longer tachyonic but is consistent with zero. See the recent preprint [13] and the more extensive discussion before the m_{ν_μ} and $m_{\pi^\pm}$ Listings.

2. There are no indications of any positive neutrino masses from any of the peak search experiments in π or K decay, or from any experiments on neutrino decays. These set good upper limits on respective lepton mixing matrix coefficients.

3. There are no indications of any positive neutrino masses from nuclear-β decay spectra. The 7-year controversy over the claim by Simpson, Hime, and others of a 17 keV neutrino is finally over, with retractions by these authors of their original claims after very strong refutations by a number of high-sensitivity experiments.

4. Certain positive claims for neutrino oscillations in reactor and accelerator neutrino experiments have either been refuted or retracted, or both (see previous editions for details).

5. There is no indication of Majorana neutrino masses from searches for neutrinoless double-β decay.

6. The situation concerning possible atmospheric neutrino oscillations remains unsettled.

It is generally acknowledged that the strongest indirect evidence for neutrino masses and mixing is the observed deficit in the solar neutrino flux. The pioneering ^{37}Cl radiochemical solar neutrino experiment of R. Davis and his group started in 1967 and, with only one 18-month gap, has been running ever since. Over the years, a deficit in the measure flux of high-energy neutrinos (mainly from the ^{8}B reaction) has been reported [14,15]. The measured flux is about three times less than the flux predicted by theoretical calculations (Refs. 16–18, and other reviews quoted therein; see also Ref. 10). More recently, Kamiokande, a large water Čerenkov detector, has produced independent high-quality measurements of the solar neutrino flux in roughly the same energy range [19,20,21]. Unlike a radiochemical experiment, a Čerenkov detector preserves directional information, and the Kamiokande collaboration has been able to demonstrate that the neutrinos come from the direction of the sun. They have confirmed the deficiency reported by Davis *et al.* The ratio of observed to expected fluxes seen by the Kamiokande group is somewhat higher than that observed by Davis, but is still significantly below unity.

Two experiments are now operating which are sensitive to the lower-energy neutrinos from the main *p-p* burning chain. These are SAGE, the Soviet-American Gallium Experiment [22], and GALLEX, a gallium experiment in the Gran Sasso Underground Laboratory [23,24]. Both of these also report a deficiency in the measured solar neutrino flux. These results are especially important since the flux of the *pp* neutrinos constitutes the dominant part of the solar neutrino flux and is widely considered to be reliably calculable. (This is not to imply that calculations of the high-energy neutrino flux are unreliable, only that they are harder to check. The high-energy part does not arise from the reactions producing most of the sun's luminosity,

but from minor side-chains which contribute only a very small fraction of the entire solar neutrino flux.)

One explanation of the results of these four experiments is that neutrino oscillations do take place during the transit from the production point in the sun to the interaction point in the earth. These oscillations may involve mixing either with ν_μ and ν_τ or "sterile" neutrino components. An appealing scenario is that of resonant neutrino oscillations, the Mikheyev-Smirnov-Wolfenstein (MSW) effect [25]. Details about this can be found in the reviews cited at the end of this note, and in the references in the original papers.

For some recent reviews on neutrino physics and further references to the original literature, see Refs. [15,26–29].

Some other sources of information on neutrinos include topical neutrino conferences, and international high-energy physics and lepton-photon conferences.

ν_e $J = \frac{1}{2}$

Not in general a mass eigenstate. See note on neutrino properties above.

These limits apply to ν_1, the primary mass eigenstate in ν_e. They would also apply to any other ν_j which mixes strongly in ν_e and has sufficiently small mass that it can occur in the respective decay. The neutrino mass may be of a Dirac or Majorana type; the former conserves total lepton number while the latter violates it. Either would violate lepton family number, since nothing forces the neutrino mass eigenstates to coincide with the neutrino interaction eigenstates. For limits on a Majorana ν_e mass, see the section on "Searches for Massive Neutrinos and Lepton Mixing," part (C), entitled "Searches for Neutrinoless Double-β Decay."

From the analysis of neutrino events from SN 1987A it is possible to get upper bounds on neutrino masses. For two examples of such studies, see Refs. 1 and 2 and references therein.

Our mass limit for ν_e is taken from the average in the ν_e "Mass Squared" section immediately below this section.

ν_e

ν_e MASS

Most of the data from which these limits are derived are from β^- decay experiments in which a $\overline{\nu}_e$ is produced, so that they really apply to $m_{\overline{\nu}_1}$. Assuming *CPT* invariance, a limit on $m_{\overline{\nu}_1}$ is the same as a limit on m_{ν_1}. Results from studies of electron capture transitions, given below "$m_{\nu_1} - m_{\overline{\nu}_1}$", give limits on m_{ν_1} itself. See also the Listings in the Neutrino Bounds from Astrophysics and Cosmology section.

[1] PDG 94 formal upper limit, as obtained from the m^2 average in the next section, is 5.1 eV at the 95%CL. Caution is urged in interpreting this result, since the m^2 average is positive with only a 3.5% probability. If the weighted average m^2 were forced to zero, the limit would increase to 7.0 eV.

[2] WEINHEIMER 93 is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[3] HOLZSCHUH 92B result is obtained from the measurement $m^2_{\nu_e} = -24 \pm 48 \pm 61$ (1σ errors), in eV^2, using the PDG prescription for conversion to a limit in m_{ν_e}.

[4] KAWAKAMI 91 experiment uses tritium-labeled arachidic acid. This result may be obtained from the $m^2_{\nu_1}$ limit by combining the errors in quadrature and using the method described in the Probability, Statistics, and Monte Carlo section in Chapter III of this *Review*. This was also done in ROBERTSON 91, although the authors report a different procedure.

[5] ROBERTSON 91 experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν_1} lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.

[6] VANDYCK 93 is a new measurement of the atomic masses of ^{3}H and ^{3}He. The authors note that "The excellent agreement with recent results from beta spectrometers lends strong support for new (upper) limits on the (electron) neutrio's rest mass."

[7] DECMAN 92 was not published in a refereed journal, so we do not use it in our compilation, but we include it for the reader's convenience. If it were included our limit would be reduced to 4.9 eV, but the average m^2 would be positive with only a 1.1% probability.

[8] KAWAKAMI 88 multiply their statistical error by the appropriate factor for 95% CL when $m^2 > 0$ is required (1.74), add this linearly to their unmultiplied systematic error (173 eV^2) and add the m^2 value (223 eV^2) to obtain their 95% CL limit (m<29 eV). To adjust for our quadratic addition of errors and our multiplication of both the statistical and systematic errors by the factor 1.645 we set the systematic error to 269 eV^2 to yield the same limit.

[9] SPERGEL 88 rule out masses greater than 16 eV.

[10] See also comment in BORIS 87B and erratum in BORIS 88.

[11] WILKERSON 87 multiply both statistical and systematic errors by 1.645 (for 95% CL), add them in quadrature and add the (negative) m^2 value (-57 eV^2) to obtain their 95% CL limit (m<27 eV).

[12] FRITSCHI 86 multiply their statistical error by 1.645 (for 95% CL), add this linearly to their unmultiplied systematic error (204 eV^2) and do NOT add in the m^2 value (-11 eV^2) to obtain their 95% CL limit (m<18 eV). To adjust for our quadratic addition of errors, and our multiplication of both the statistical and systematic errors by the factor 1.645, we set the systematic error to 178 eV^2.

ν_e MASS SQUARED

The tritium experiments actually measure mass squared. A combined limit on mass must therefore be obtained from the weighted average of the results shown here. The recent results are in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88, erratum)] that m_{ν_1} lies between 17 and 40 eV. The BORIS 87 result is excluded because of the controversy over the possibly large unreported systematic errors; see BERGKVIST 85B, BERGKVIST 86, SIMPSON 84, and REDONDO 89. However, the average for the new experiments given below implies only a 3.5% probability that m^2 is positive. See HOLZSCHUH 92 for a review of the recent direct m_{ν_1} measurements.

[13] WEINHEIMER 93 is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[14] HOLZSCHUH 92B source is a monolayer of tritiated hydrocarbon.

[15] KAWAKAMI 91 experiment uses tritium-labeled arachidic acid.

[16] ROBERTSON 91 experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν_1} lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.

[17] DECMAN 92 was not published in a refereed journal, so we do not use it in our compilation, but we include it for the reader's convenience. If it were included, our average would be -58 ± 26 eV^2.

[18] KAWAKAMI 88 multiply their statistical error by the appropriate factor for 95% CL when $m^2 > 0$ is required (1.74), add this linearly to their unmultiplied systematic error (173 eV^2) and add the m^2 value (223 eV^2) to obtain their 95% CL limit (m<29 eV). To adjust for our quadratic addition of errors and our multiplication of both the statistical and systematic errors by the factor 1.645 we set the systematic error to 269 eV^2 to yield the same limit.

[19] WILKERSON 87 multiply both statistical and systematic errors by 1.645 (for 95% CL), add them in quadrature and add the (negative) m^2 value (-57 eV^2) to obtain their 95% CL limit (m<27 eV).

[20] FRITSCHI 86 multiply their statistical error by 1.645 (for 95% CL), add this linearly to their unmultiplied systematic error (204 eV^2) and do NOT add in the m^2 value (-11 eV^2) to obtain their 95% CL limit (m<18 eV). To adjust for our quadratic addition of errors, and our multiplication of both the statistical and systematic errors by the factor 1.645, we set the systematic error to 178 eV^2.

$m_{\nu_1} - m_{\overline{\nu}_1}$

These are measurement of m_{ν_1} (in contrast to $m_{\overline{\nu}_1}$, given above). The masses can be different for a Dirac neutrino in the absense of *CPT* invariance. The test is not very strong.

[24] REINES 74 looked for ν_e of nonzero mass decaying to a neutral of lesser mass + γ. Used liquid scintillator detector near fission reactor. Finds lab lifetime $6. \times 10^7$ s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit $6. \times 10^7$ s REINES 74 assumed that the full $\overline{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV – 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (P. Vogel, private communication, 1984).

[25] BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

[26] Nonobservation of γ's in coincidence with ν's from SN 1987A.

[27] KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.3a^2 + 9.8a + 15.9)$ s/eV, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[28] CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

[29] COWSIK 89 use observations of supernova SN 1987A to set the limit for the lifetime of a neutrino with $1 < m < 50$ MeV decaying through $\nu_H \rightarrow \nu_1 e e$ to be $\tau > 4 \times 10^{15}$ $\exp(-m/5$ MeV) s.

[30] RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3 > 3 \times 10^{18}$ s eV^3 (based on $\overline{\nu}_e e^-$ cross sections). The bound is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.

[31] RAFFELT 89B analyze stellar evolution and exclude the region $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21}$ s eV^3.

[32] BOUCHEZ 88 reports limits in the nearly degenerate mass case.

[33] Model-dependent theoretical analysis of SN 1987A neutrinos.

[34] OBERAUER 87 bounds are from comparison of observed and expected rate of reactor neutrinos.

[35] RAFFELT 85 limit is from solar x- and γ-ray fluxes.

[36] HENRY 81 uses UV flux from clusters of galaxies to find $\tau > 1.1 \times 10^{25}$ s for radiative decay.

[37] KIMBLE 81 uses extreme UV flux limits to find $\tau > 10^{22}$–10^{23} s.

[38] STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at $m_\nu = 20$ eV.

$|(v - c)/c|$ ($v \equiv \nu_1$ VELOCITY)

Expected to be zero for massless neutrino, but tests also whether photons and neutrinos have the same limiting velocity in vacuum.

VALUE (units 10^{-8})	EVTS	DOCUMENT ID		TECN	COMMENT
<1	17	[39] STODOLSKY	88	ASTR	SN 1987A

[39] STODOLSKY 88 result based on <10 hr between $\overline{\nu}_e$ detection in IMB and KAMI detectors and beginning of light signal. Inclusion of the problematic 5 neutrino events from FREJ (four hours later) does not change the result.

ν_1 MAGNETIC MOMENT

Must vanish for Majorana neutrino or purely chiral massless Dirac neutrino. The value of the magnetic moment for the standard SU(2)×U(1) electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) is $\mu_\nu = 3eG_F m_\nu/(8\pi^2\sqrt{2}) = (3.20 \times 10^{-19}) m_\nu \mu_B$ where m_ν is in eV and $\mu_B = e\hbar/2m_e$ is the Bohr magneton. Given the upper bound $m_{\nu_1} < 7.3$ eV, it follows that for the extended standard electroweak theory, $\mu(\nu_1) < 2.3 \times 10^{-18}$ μ_B. Current experiments are not yet challenging this limit. There is considerable controversy over the validity of many of the claimed upper limits on the magnetic moment from the astrophysical data. For example, VOLOSHIN 90 states that "in connection with the astrophysical limits on μ_ν, ... there is by now a general consensus that contrary to the initial claims (BARBIERI 88, LATTIMER 88, GOLDMAN 88, NOTZOLD 88), essentially no better than quoted limits (from previous constraints) can be derived from detection of the neutrino flux from the supernova SN1987A." See VOLOSHIN 88 and VOLOSHIN 88C.

[40] KRAKAUER 90 experiment fully reported in ALLEN 93.

[41] VIDYAKIN 92 limit is from a $(enu)_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

[42] FIORENTINI 91 is a study of the statistical significance of possible correlation of solar neutrino flux with sunspot cycle. Data do not imply any evidence for a nonzero neutrino magnetic moment, although they are consistent with a moment of order $1 \times 10^{-10}/\mu_B$.

[43] RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_C.

[44] Significant dependence on details of stellar models.

[45] A limit of 10^{-13} is obtained with even more model-dependence.

[46] These papers have assumed that the right-handed neutrino is inert; see BARBIERI 88B.

[47] FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16}$ $[10^{-9}$ $G/B_0]$ where B_0 is the present-day intergalactic field strength.

[48] Some dependence on details of stellar models.

[49] We obtain above limit from SUTHERLAND 76 using their limit $f < 1/3$.

NONSTANDARD CONTRIBUTIONS TO NEUTRINO SCATTERING

We report limits on the so-called neutrino charge radius squared in this section. This quantity is not an observable, physical quantity and this is reflected in the fact that it is gauge dependent (see LEE 77C). It is not necessarily positive. A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

ν_μ

$J = \frac{1}{2}$

Not in general a mass eigenstate. See note on neutrinos in the ν_e section above.

NOTE ON THE MUON NEUTRINO MASS*

Particle-physics limits (as opposed to those from astrophysics) for the mass of the muon neutrino m_{ν_μ} come from measurements of the muon momentum p_μ in the decay $\pi^+ \to \mu^+\nu_\mu$. For π^+ decay at rest,

$$m^2_{\nu_\mu} = m^2_\pi + m^2_\mu - 2m_\pi\sqrt{m^2_\mu + p^2_\mu}\ . \qquad (1)$$

The DAUM 91 determination of p_μ for π^+ decay at rest,

$$p_\mu = 29.79177 \pm 0.00024\ \text{MeV}/c,$$

has been followed by an even more precise but not yet published measurement by the same group (ASSAMAGAN 94):

$$p_\mu = 29.79207 \pm 0.00012\ \text{MeV}/c$$

The 1986 CODATA value for the muon mass is 105.658389 ± 0.000034 MeV. A present ambiguity concerning the pion mass is discussed in the $\pi^\pm$ section of these Listings; the two values of m_π from a recent paper, JECKELMANN 94, are given in Table 1. The corresponding values of $m^2_{\nu_\mu}$ obtained using Eq. (1) are also given. Using the ASSAMAGAN 94 p_μ value, one finds for Solution A that $m^2_{\nu_\mu}$ is negative by 6.1 standard deviations, while for Solution B, $m^2_{\nu_\mu}$ is negative by 0.9 standard deviations.

Table 1: Values for $m^2_{\nu_\mu}$ obtained using the unpublished ASSAMAGAN 94 measurement of p_μ and the two JECKELMANN 94 solutions for m_π.

	m_π (MeV)	$m^2_{\nu_\mu}$ (MeV^2)
Solution A	139.56782 ± 0.00037	-0.149 ± 0.025
Solution B	139.56995 ± 0.00035	-0.022 ± 0.023

Alternatively, one can calculate $m^2_{\nu_\mu}$ as a function of m_π. This function is shown in Fig. 1, along with the two π^- mass solutions of JECKELMANN 94.

Much of this analysis follows that of Robertson [1], who concluded (before Solution B was known to be viable) that we should revert to the ANDERHUB 82 limit, $m_{\nu_\mu} \leq 0.50$ MeV at the 90% CL. In that experiment, the momentum of forward-going muons from pion decay in flight was measured. The kinematics are such that the sensitivity of $m^2_{\nu_\mu}$ to m_π and m_μ decreases as the energy increases, so that the need for an independent precise measurement of $m_{\pi^\pm}$ mass is bypassed. However, the result, $m^2_{\nu_\mu} = -0.14 \pm 0.20$ MeV^2, has an error large enough to include both of the solutions shown in Fig. 1. In principle, this kind of experiment might resolve the present ambiguity. In practice, experiments on pionic x-rays in lower-Z materials, which have just begun at the Paul Scherrer Institute, are likely to resolve the ambiguity [2].

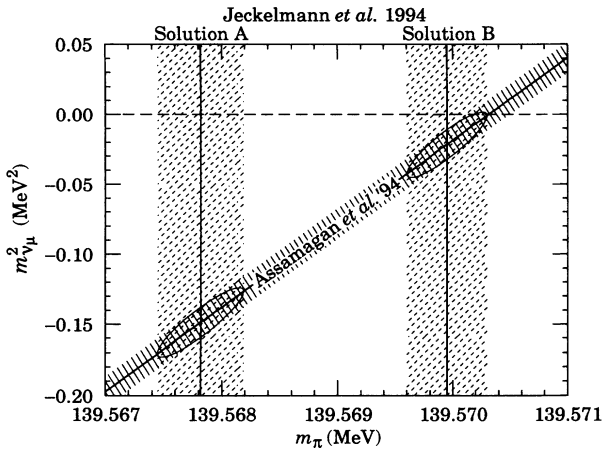

Figure 1: $m^2_{\nu_\mu}$ as a function of $\pi^\pm$ mass. The ASSAMAGAN 94 measurement of the momentum of the muon in π^+ decay at rest is represented by the diagonal line with the 1σ error band from uncertainties in p_μ and m_μ. The two solutions for the π^- mass from the JECKELMANN 94 reanalysis are shown by the vertical lines, along with their 1σ error bands. Also shown are the 1σ error ellipses from the combined fits.

Since $m^2_{\nu_\mu}$ must be nonnegative and to obtain the more conservative limit, we choose the new JECKELMANN 94 Solution B for the pion mass, and take the corresponding value $m^2_{\nu_\mu} = 0.001 \pm 0.044$ MeV^2. Using a Bayesian procedure with a flat prior distribution, we find $m^2_{\nu_\mu} < 0.073$ MeV^2 at the 90% CL, and so list $m_{\nu_\mu} < 0.27$ MeV at the 90% CL.

If, instead, we apply the same procedure using p_μ from the as yet unpublished ASSAMAGAN 94 and the Solution B pion mass from JECKELMANN 94, we obtain $m^2_{\nu_\mu} = -0.022 \pm 0.023$ MeV^2, or $m_{\nu_\mu} < 0.17$ MeV at the 90% CL.

ν_μ MASS

Applies to ν_2, the primary mass eigenstate in ν_μ. Would also apply to any other ν_j which mixes strongly in ν_μ and has sufficiently small mass that it can occur in the respective decays. (This would be nontrivial only for $J \geq 3$, given the ν_e mass limit above.) See also the Listings in the Neutrino Bounds from Astrophysics and Cosmology section.

[1] ASSAMAGAN 94 result is from a new measurement of p_μ from $\pi^+ \to \mu^+\nu_\mu$ at rest combined with JECKELMANN 94 Solution B pion mass. It is not used in "OUR EVALUATION" because it is not yet published. See Note above.

[2] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.

[3] MAYLE 93 recalculates cooling rate enhancement by escape of wrong-helicity Dirac neutrinos using the Livermore Supernova Explosion Code, obtains more restrictive result than the "very conservative" BURROWS 92 limit because of higher core temperature.

[4] There would be an increased cooling rate if Dirac neutrino mass is included; this does not apply for Majorana neutrinos. Limit is on $\sqrt{m^2_{\nu_\mu} + m^2_{\nu_\tau}}$, and error becomes very large if ν_τ is nonrelativistic, which occurs near the lab limit of 31 MeV. RAJPOOT 93 notes that limit could be evaded with new physics.

[5] BURROWS 92 limit for Dirac neutrinos only.

[6] Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.

[7] NATALE 91 published result multiplied by $\sqrt{8}\sqrt{4}$ at the advice of the author.

[8] GRIFOLS 90B estimated error is a factor of 3.

[9] GAEMERS 89 published result (< 0.03) corrected via the GANDHI 91 erratum.

[10] ABELA 84 used the PDG 84 value for $\pi^\pm$ mass, in conjunction with μ momentum measurement in $\pi \to \mu\nu_\mu$ decay to obtain $m < 0.25$ and $m^2 = -0.16 \pm 0.08$. The values shown here for mass and m^2 are corrected values obtained by JECKELMANN 86 from the ABELA 84 data using the more accurate $\pi^\pm$ mass of JECKELMANN 86.

[11] LU 80 combines DAUM 79 $\pi^+ \to \mu^+\nu_\mu$ measurement with new LU 80 π^- mass and replaces DAUM 79. LU 80 is not independent of ABELA 84.

$m_{\nu_2} - m_{\overline{\nu}_2}$

Test of *CPT* for a Dirac neutrino. (Not a very strong test.)

[12] KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3)$ s/eV, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ The parameter $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[13] BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

[14] Nonobservation of γ's in coincidence with ν's from SN 1987A. Results should be divided by the $\tau_\nu \to \gamma X$ branching ratio.

[15] DODELSON 92 range is for wrong-helicity keV mass Dirac ν's from the core of neutron star in SN 1987A decaying to ν's that would have interacted in KAM2 or IMB detectors.

[16] CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

[17] Model-dependent theoretical analysis.

[18] HATSUDA 88 argues that previous bounds on radiative decays of neutrinos produced in supernovae explosions may not be valid (because $\nu_H \to \gamma\nu$ might be dominated by processes such as $\nu_H e \to \nu e$ if e number density is high enough), and that, in fact, a neutrino mean life/mass of 0.2–0.6 s/eV may be consistent with the data.

[19] Model-dependent theoretical analysis of SN 1987A neutrinos.

[20] Limit applies to ν_τ also.

[21] These experiments look for $\nu_\mu \to \nu_e\gamma$ or $\overline{\nu}_\mu \to \overline{\nu}_e\gamma$.

[22] HENRY 81 uses UV flux from clusters of galaxies to find $\tau > 1.1 \times 10^{25}$ s for radiative decay.

[23] KIMBLE 81 uses extreme UV flux limits to find $\tau > 10^{22}$–10^{23} s.

[24] REPHAELI 81 consider ν decay γ effect on neutral H in early universe; based on M31 HI concludes $\tau > 10^{24}$ s.

[25] DERUJULA 80 finds $\tau > 3 \times 10^{23}$ s based on CDM neutrino decay contribution to UV background.

[26] STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at $m_\nu = 20$ eV.

$|(v - c)/c|$ ($v \equiv \nu_2$ VELOCITY)

Expected to be zero for massless neutrino, but also tests whether photons and neutrinos have the same limiting velocity in vacuum.

ν_2 MAGNETIC MOMENT

Must vanish for Majorana neutrino or purely chiral massless Dirac neutrino. The value of the magnetic moment for the standard SU(2)×U(1) electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) is $\mu_\nu = 3eG_F m_\nu/(8\pi^2\sqrt{2}) = (3.2 \times 10^{-19}) m_\nu \mu_B$ where m_ν is in eV and $\mu_B = e\hbar/2m_e$ is the Bohr magneton. Given the upper bound $m_{\nu_2} < 0.27$ MeV, it follows that for the extended standard electroweak theory, $\mu(\nu_2) < 0.86 \times 10^{-13}\ \mu_B$.

[27] KRAKAUER 90 experiment fully reported in ALLEN 93.

[28] DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν_2 magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $\nu_\mu e$ and $\overline{\nu}_\mu e$ elastic scattering and assume $\mu(\nu_\mu) = \mu(\overline{\nu}_\mu)$.

[29] RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_C.

[30] Significant dependence on details of stellar properties.

[31] If $m_{\nu_2} < 10$ keV.

[32] For $m_{\nu_2} = 8$–200 eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\mu \to \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_{\nu_2} > 16$ eV and $< 6 \times 10^{-14}$ for $m_{\nu_2} > 4$ eV.

[33] KIM 74 is a theoretical analysis of $\overline{\nu}_\mu$ reaction data.

[34] If $m_{\nu_2} < 1$ keV.

NONSTANDARD CONTRIBUTIONS TO NEUTRINO SCATTERING

We report limits on the so-called neutrino charge radius squared in this section. This quantity is not an observable, physical quantity and this is reflected in the fact that it is gauge dependent (see LEE 77C). It is not necessarily positive. A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

ν_τ

$J = \frac{1}{2}$

Existence indirectly established from τ decay data combined with ν reaction data. See for example FELDMAN 81. ALBRECHT 92Q rules out $J = 3/2$ by establishing that the ρ^- is not in a pure $H_\rho = -1$ helicity state in $\tau^- \to \rho^- \nu_\tau$.

Not in general a mass eigenstate. See note on neutrinos in the ν_e section above.

ν_τ MASS

Applies to ν_3, the primary mass eigenstate in ν_τ. Would also apply to any other ν_j which mixes strongly in ν_τ and has sufficiently small mass that it can occur in the respective decays. (This would be nontrivial only for a hypothetical $J \geq 4$, given the ν_e and ν_μ mass limits above.) See also the Listings in the Neutrino Bounds from Astrophysics and Cosmology section.

[1] ALBRECHT 92M reports measurement of a slightly lower τ mass, which has the effect of reducing the ν_τ mass reported in ALBRECHT 88B. Bound is from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ mode.

[2] BALEST 93 derive limit by comparing their m_τ measurement (which depends on m_{ν_τ}) to BAI 92 and BACINO 78B m_τ threshold measurements.

[3] CINABRO 93 bound comes from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \to 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.

[4] DOLGOV 93 assumes neutrino lifetime >100 s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment.

[5] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.

[6] MAYLE 93 recalculates cooling rate enhancement by escape of wrong-helicity Dirac neutrinos using the Livermore Supernova Explosion Code, obtains more restrictive result than the "very conservative" BURROWS 92 limit because of higher core temperature.

[7] There would be an increased SN 1987A cooling rate if Dirac neutrino mass is included; this does not apply for Majorana neutrinos. Limit is on $\sqrt{m^2_{\nu_\mu} + m^2_{\nu_\tau}}$, and error becomes very large if ν_τ is nonrelativistic, which occurs near the lab limit of 31 MeV. RAJPOOT 93 notes that limit could be evaded with new physics.

[8] BURROWS 92 limit for Dirac neutrinos only.

[9] Assumes neutrino lifetime >1 s. For Dirac neutrinos. See also ENQVIST 93.

[10] KOLB 91 exclusion region is for Dirac neutrino with lifetime >1 s; other limits are given.

[11] NATALE 91 published result multiplied by $\sqrt{8}\sqrt{4}$ at the advice of the author.

[12] GRIFOLS 90B estimated error is a factor of 3.

[13] GAEMERS 89 published result (< 0.03) corrected via the GANDHI 91 erratum.

[14] ALBRECHT 88 bound comes from analysis of $\tau \to 5\pi^\pm \nu_\tau$ decay mode. Same data reanalyzed with revised τ mass in ALBRECHT 92M.

[15] Bound comes from analysis of $\tau \to 5\pi^\pm (\pi^0) \nu_\tau$ decay mode in 13 decay events.

[16] CSORNA 87B also quote result as 31 ± 25 ± 20 MeV. Bound comes from analysis of $\tau \to 3\pi^\pm (\pi^0) \nu_\tau$ decay mode.

[17] Bound comes from analysis of $\tau \to 5\pi^\pm \pi^0 \nu_\tau$ decay mode (5 events) and to a lesser extent from $\tau \to 5\pi^\pm \nu_\tau$ mode (5 events).

[18] Bound comes from analysis of $\tau \to 3\pi^\pm \nu_\tau$ decay mode.

[19] Bound comes from analysis of $\tau \to 5\pi^\pm (\pi^0) \nu_\tau$ decay.

[20] Bound comes from analysis of $\tau \to 3\pi^\pm \pi^0 \nu_\tau$ decay mode.

[21] Bound comes from analysis of $\tau \to K^\pm K^\mp \pi^\pm \nu_\tau$ decay mode.

[22] Bound comes from analysis of $\tau \to \pi \nu_\tau$ decay mode.

[23] Bound comes from analysis of leptonic decay spectrum.

[24] BACINO 79B experiment rules out V+A decay, disfavors pure V or A, and is in good agreement with $V-A$.

ν_3 (MEAN LIFE) / MASS

These limits often apply to ν_μ (ν_2) also.

$<3 \times 10^{-11}$	[42] FALK	78	ASTR	m_ν <10 MeV
	[43] COWSIK	77	ASTR	

[25] BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

[26] Nonobservation of γ's in coincidence with ν's from SN 1987A. Results should be divided by the $\tau_\nu \to \gamma X$ branching ratio.

[27] DODELSON 92 range is for wrong-helicity keV mass Dirac ν's from the core of neutron star in SN 1987A decaying to ν's that would have interacted in KAM2 or IMB detectors.

[28] GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where m_{ν_L} <100 keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$, and m_{ν_L}.

[29] WALKER 90 uses SN 1987A γ flux limits after 289 days to find $m_\tau > 1.1 \times 10^{15}$ eV s.

[30] CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

[31] TERASAWA 88 finds only $10^2 < \tau < 10^4$ allowed for 30–70 MeV ν's from primordal nucleosynthesis.

[32] KAWASAKI 86 concludes that light elements in primordal nucleosynthesis would be destroyed by radiative decay of neutrinos with 10 MeV< m_ν <1 GeV unless $\tau \lesssim 10^4$ s.

[33] LINDLEY 85 considers destruction of cosmologically-produced light elements, and finds $\tau < 2 \times 10^3$ s for 10 MeV < m_ν <100 MeV. See also LINDLEY 79.

[34] BINETRUY 84 finds $\tau < 10^8$ s for neutrinos in a radiation-dominated universe.

[35] SARKAR 84 finds $\tau <$ 20 s at m_ν=10 MeV, with higher limits for other m_ν, and claims that all masses between 1 MeV and 50 MeV are ruled out.

[36] HENRY 81 uses UV flux from clusters of galaxies to find $\tau > 1.1 \times 10^{25}$ s for radiative decay.

[37] KIMBLE 81 uses extreme UV flux limits to find $\tau > 10^{22}$–10^{23} s.

[38] REPHAELI 81 consider ν decay γ effect on neutral H in early universe; based on M31 HI concludes $\tau > 10^{24}$ s.

[39] DERUJULA 80 finds $\tau > 3 \times 10^{23}$ s based on CDM neutrino decay contribution to UV background.

[40] STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at m_ν = 20 eV.

[41] DICUS 78 considers effect of ν decay photons on light-element production, and finds lifetime must be less than "hours." See also DICUS 77.

[42] FALK 78 finds lifetime constraints based on supernova energetics.

[43] COWSIK 77 considers varity of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau > 10^{23}$ s for $m_\nu \sim$ 1 eV. See also COWSIK 79 and GOLDMAN 79.

Lepton & Quark Full Listings

ν_τ, e

ν_3 MAGNETIC MOMENT

Must vanish for Majorana neutrino or purely chiral massless Dirac neutrino. The value of the magnetic moment for the standard SU(2)×U(1) electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) is $\mu_\nu = 3eG_F m_\nu/(8\pi^2\sqrt{2}) = (3.20\times10^{-19})m_\nu\mu_B$ where m_ν is in eV and $\mu_B = e\hbar/2m_e$ is the Bohr magneton. Given the upper bound $m_{\nu_3} < 35$ MeV, it follows that for the extended standard electroweak theory, $\mu(\nu_3) < 1.1\times10^{-11}\ \mu_B$.

[44] COOPER-SARKAR 92 assume $f_{D_s}/f_\pi = 2$ and D_s, $\overline{D}_s$ production cross section = 2.6 μb to calculate ν_τ flux.

[45] KAWANO 92 lower limit is that needed to circumvent ^{4}He production if m_{ν_τ} is between 5 and ~ 30 MeV/c^2.

[46] RAFFELT 90 limit valid if $m_{\nu_3} < 5$ keV. It applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4\times10^{-12}$. Limit at 95%CL obtained from δM_C.

[47] Significant dependence on details of stellar properties.

[48] GROTCH 88 combined data from MAC, ASP, CELLO, and Mark J.

[49] If $m_{\nu_3} < 10$ keV.

[50] For m_{ν_3} = 8–200 eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\tau \to \nu_e$ and obtain $< 3\times10^{-15}$ for $m_{\nu_3} < 16$ eV and $< 6\times10^{-14}$ for $m_{\nu_3} > 4$ eV.

LIMIT ON ν_τ PRODUCTION IN BEAM DUMP EXPERIMENT

VALUE	DOCUMENT ID		TECN
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	[51] DORENBOS...	88	CHRM
	[52] BOFILL	87	CNTR
	[53] TALEBZADEH	87	BEBC
	[54] USHIDA	86C	EMUL
	[55] ASRATYAN	81	HLBC
	[56] FRITZE	80	BEBC

[51] DORENBOSCH 88 is CERN SPS beam dump experiment with the CHARM detector. $\nu_\tau+\overline{\nu}_\tau$ flux is <21% of the total prompt flux at 90% CL.

[52] BOFILL 87 is a Fermilab narrow-band ν beam with a fine-grained neutrino detector.

[53] TALEBZADEH 87 is a CERN SPS beam dump experiment with the BEBC detector. Mixing probability $P(\nu_e \to \nu_\tau)$ <18% at 90% CL.

[54] USHIDA 86C is a Fermilab wide-band ν beam with a hybrid emulsion spectrometer. Mixing probabilities $P(\nu_e \to \nu_\tau) < 7.3\%$ and $P(\nu_\mu \to \nu_\tau) < 0.2\%$ at 90% CL.

[55] ASRATYAN 81 is a Fermilab wide-band $\overline{\nu}$ beam with a 15 foot bubble chamber. Mixing probability $P(\overline{\nu}_\mu \to \overline{\nu}_\tau) < 2.2\%$ at 90% CL.

[56] FRITZE 80 is CERN SPS experiment with BEBC. Neutral-current/charged-current ratio corresponds to R = (prompt-ν_τ-induced events)/(all prompt-ν events) <0.1. Mixing probability $P(\nu_e \to \nu_\tau)$ <0.35 at CL = 90%.

e MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45,** 1 June, Part II (1992), p. VI.10). We use the best "disappearance" limit for the Summary Tables. The best limit for the specific channel $e^- \to \nu\gamma$ is much better.

Note that we use the mean life rather than what is often reported, the half life.

105.65865 ±0.00044	[7] CRANE	71	CNTR		

[1] The mass is known more precisely in u: m = 0.113428913 ± 0.000000017 u. COHEN 87 makes use of the other entries below.

[2] BELTRAMI 86 gives m_μ/m_e = 206.76830(64).

[3] KLEMPT 82 gives m_μ/m_e = 206.76835(11).

[4] MARIAM 82 gives m_μ/m_e = 206.768259(62).

[5] CASPERSON 77 gives m_μ/m_e = 206.76859(29).

[6] CROWE 72 gives m_μ/m_e = 206.7682(5).

[7] CRANE 71 gives m_μ/m_e = 206.76878(85).

$3.1833467\ \pm0.0000082$	CROWE	72	CNTR	+	Precession phase

[10] COHEN 87 (1986 CODATA) value was fitted using their own selection of the following data. Because their value is from a multiparameter fit, correlations with other quantities may be important and one cannot arrive at this result by any average of these data alone.

μ^- DECAY MODES

μ^+ modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Confidence level
Γ_1	$e^-\overline{\nu}_e\nu_\mu$		$\approx 100\%$	
Γ_2	$e^-\overline{\nu}_e\nu_\mu\gamma$		[a] $(1.4\pm0.4)\ \%$	
Γ_3	$e^-\overline{\nu}_e\nu_\mu e^+e^-$		[b] $(3.4\pm0.4)\times10^{-5}$	
	Lepton Family number (*LF*) violating modes			
Γ_4	$e^-\nu_e\overline{\nu}_\mu$	*LF*	[c] < 1.2 %	90%
Γ_5	$e^-\gamma$	*LF*	$< 4.9\times10^{-11}$	90%
Γ_6	$e^-e^+e^-$	*LF*	$< 1.0\times10^{-12}$	90%
Γ_7	$e^-2\gamma$	*LF*	$< 7.2\times10^{-11}$	90%

[a] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\nu_\mu$ and $e^-\overline{\nu}_e\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[b] See the Full Listings below for the energy limits used in this measurement.

[c] A test of additive vs. multiplicative lepton family number conservation.

NOTE ON MUON DECAY PARAMETERS

(by W. Fetscher and H.-J. Gerber, ETH Zürich)

All measurements in direct muon decay, $\mu^- \to e^- + 2$ neutrals, and its inverse, $\nu_\mu + e^- \to \mu^-$ + neutral, are successfully described by the "V–A interaction," which is a particular case of a local, derivative-free, lepton-number-conserving, four-fermion interaction [1]. The matrix element is given below. The V–A form and the nature of the neutrals (ν_μ and $\overline{\nu}_e$), and hence the doublet assignments $(\nu_e\, e^-)_L$ and $(\nu_\mu\, \mu^-)_L$, can be determined from experiments [2,3].

All results in direct muon decay (energy spectra, polarizations, and angular distributions) and in inverse muon decay (the reaction cross section) at energies well below $m_W c^2$ may be parametrized in terms of amplitudes $g^\gamma_{\varepsilon\mu}$ and the Fermi coupling constant G_F, using the matrix element

$$\frac{4G_F}{\sqrt{2}} \sum_{\substack{\gamma=S,V,T \\ \epsilon,\mu=R,L}} g^\gamma_{\epsilon\mu} \langle \overline{e}_\epsilon \,|\, \Gamma^\gamma \,|\, (\nu_e)_n \rangle \, \langle (\overline{\nu}_\mu)_m \,|\, \Gamma_\gamma \,|\, \mu_\mu \rangle \ . \qquad (1)$$

We use the notation of Fetscher *et al.* [2], who in turn use the sign conventions and definitions of Scheck [4]. Here $\gamma = S, V, T$ indicate a scalar, vector, or tensor interaction; and $\varepsilon, \mu = R, L$ indicate a right- or left-handed chirality of the electron or muon. The chiralities n and m of the ν_e and $\overline{\nu}_\mu$ are then determined by the values of γ, ε, and μ. The particles are represented by fields of definite chirality [5].

As shown by Langacker and London [6], explicit lepton-number nonconservation still leads to a matrix element equivalent to Eq. (1). They conclude that it is not possible, even in principle, to test lepton-number conservation in (leptonic) muon decay if the final neutrinos are massless and are not observed.

The ten complex amplitudes $g^\gamma_{\varepsilon\mu}$ (g^T_{RR} and g^T_{LL} are identically zero) and G_F constitute 19 independent (real) parameters to be determined by experiment. The V–A interaction corresponds to the single amplitude g^V_{LL} being unity and all the others being zero.

C. Jarlskog [7] has noted that certain experiments observing the decay electron are especially informative if they yield the V–A values. Indeed, all (direct) muon decay experiments are compatible with an arbitrary mix of the scalar and vector amplitudes g^S_{LL} and g^V_{LL}—in the extreme, even with the purely scalar $g^S_{LL} = 2$, $g^V_{LL} = 0$. The decision in favor of V–A comes from the quantitative observation of inverse muon decay, which would be forbidden for pure g^S_{LL} [2].

The differential decay probability to obtain an $e^\pm$ with (reduced) energy between x and $x + dx$, emitted in the direction $\widehat{z}$ at an angle between θ and $\theta + d\theta$ with respect to the muon polarization vector $\vec{P}_\mu$, and with its spin pointing in the arbitrary direction $\widehat{\zeta}$, is given by

$$\frac{d^2\Gamma}{dx\, d\cos\theta} = \frac{m_\mu}{4\pi^3} W^4_{e\mu} G_F^2 \sqrt{x^2 - x_0^2} \times \Big(F_{IS}(x) \pm P_\mu \cos\theta\, F_{AS}(x) \Big) \times [1 + \vec{P}_e(x,\theta) \cdot \widehat{\zeta}] \ .$$

Here $W_{e\mu} = \max(E_e) = (m_\mu^2 + m_e^2)/2m_\mu$ is the maximum $e^\pm$ energy, $x = E_e/W_{e\mu}$ is the reduced energy, and $x_0 = m_e/W_{e\mu} = 9.67 \times 10^{-3}$. The quantity $P_\mu = |\vec{P}_\mu| \cdot \widehat{\zeta}$ has the significance of the direction in which a perfect polarization-sensitive electron detector would be most sensitive. The isotropic part of the spectrum, $F_{IS}(x)$, the anisotropic part, $F_{AS}(x)$, and the electron polarization, $\vec{P}_e(x,\theta)$, depend on bilinear combinations—called decay parameters—of the coupling constants $g^\gamma_{\varepsilon\mu}$. Neglecting possible nonzero neutrino masses, we have, in terms of the decay parameters ρ, η, ξ, δ, etc.,

$$F_{IS}(x) = x(1-x) + \tfrac{2}{9}\rho(4x^2 - 3x - x_0^2) + \eta\, x_0 (1-x)$$

$$F_{AS}(x) = \tfrac{1}{3}\xi \sqrt{x^2 - x_0^2} \times \left[1 - x + \tfrac{2}{3}\delta\Big(4x - 3 - \big(\sqrt{1 - x_0^2} - 1\big) \Big) \right]$$

$$\vec{P}_e(x,\theta) = P_{T_1}\, \widehat{x} + P_{T_2}\, \widehat{y} + P_L\, \widehat{z} \ .$$

Here $\hat{x}$, $\hat{y}$, and $\hat{z}$ are orthogonal unit vectors defined as follows:

$\hat{z}$ is along the e momentum

$\hat{y} = [\hat{z} \times \vec{P}_\mu]/|[\hat{z} \times \vec{P}_\mu]|$ is transverse to the e momentum and perpendicular to the "decay plane"

$\hat{x} = \hat{y} \times \hat{z}$ is transverse to the e momentum and in the "decay plane."

The components of $\vec{P}_e$ then are given by

$$P_{T_1}(x,\theta) = P_\mu \sin\theta\, F_{T_1}(x) \Big/ \Big(F_{IS}(x) \pm P_\mu \cos\theta\, F_{AS}(x)\Big)$$

$$P_{T_2}(x,\theta) = P_\mu \sin\theta\, F_{T_2}(x) \Big/ \Big(F_{IS}(x) \pm P_\mu \cos\theta\, F_{AS}(x)\Big)$$

$$P_L(x,\theta) = \pm F_{IP}(x) + P_\mu \cos\theta \times F_{AP}(x) \Big/ \Big(F_{IS}(x) \pm P_\mu \cos\theta\, F_{AS}(x)\Big) ,$$

where

$$F_{T_1}(x) = \tfrac{1}{12}\Big\{-2\Big[\xi'' + 12(\rho - \tfrac{3}{4})\Big](1-x)x_0 - 3\eta(x^2 - x_0^2) + \eta''(-3x^2 + 4x - x_0^2)\Big\}$$

$$F_{T_2}(x) = \tfrac{1}{3}\sqrt{x^2 - x_0^2}\,\Big\{3\frac{\alpha'}{A}(1-x) + 2\frac{\beta'}{A}\sqrt{1-x_0^2}\Big\}$$

$$F_{IP}(x) = \tfrac{1}{54}\sqrt{x^2 - x_0^2}\,\Big\{9\xi'\Big(-2x + 2 + \sqrt{1-x_0^2}\Big) + 4\xi(\delta - \tfrac{3}{4})\Big(4x - 4 + \sqrt{1-x_0^2}\Big)\Big\}$$

$$F_{AP}(x) = \tfrac{1}{6}\Big\{\xi''(2x^2 - x - x_0^2) + 4(\rho - \tfrac{3}{4})(4x^2 - 3x - x_0^2) + 2\eta''(1-x)x_0\Big\} .$$

For the experimental values of the decay parameters ρ, ξ, ξ', ξ'', δ, η, η'', α/A, β/A, α'/A, β'/A, which are not all independent, see the Data Listings below. Experiments in the past have also been analyzed using the parameters a, b, c, a', b', c', α/A, β/A, α'/A, β'/A (and $\eta = (\alpha - 2\beta)/2A$), as defined by Kinoshita and Sirlin [8]. They serve as a model-independent summary of all possible measurements on the decay electron (see Listings below). The relations between the two sets of parameters are

$$\rho - \frac{3}{4} = \frac{3}{4}(-a + 2c)/A ,$$

$$\eta = (\alpha - 2\beta)/A ,$$

$$\eta'' = (3\alpha + 2\beta)/A ,$$

$$\delta - \frac{3}{4} = \frac{9}{4} \cdot \frac{(a' - 2c')/A}{1 - [a + 3a' + 4(b+b') + 6c - 14c']/A} ,$$

$$1 - \xi\frac{\delta}{\rho} = 4\frac{[(b+b') + 2(c-c')]/A}{1 - (a - 2c)/A} ,$$

$$1 - \xi' = [(a+a') + 4(b+b') + 6(c+c')]/A ,$$

$$1 - \xi'' = (-2a + 20c)/A ,$$

where

$$A = a + 4b + 6c .$$

The relations to the coupling constants are:

$$a = 16(|g_{RL}^V|^2 + |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 + |g_{LR}^S + 6g_{LR}^T|^2 ,$$

$$a' = 16(|g_{RL}^V|^2 - |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 - |g_{LR}^S + 6g_{LR}^T|^2 ,$$

$$\alpha = 8\,\mathrm{Re}\Big[g_{RL}^V(g_{LR}^S + 6g_{LR}^T)^* + g_{LR}^V(g_{RL}^S + 6g_{RL}^T)^*\Big] ,$$

$$\alpha' = 8\,\mathrm{Im}\Big[-g_{LR}^V(g_{RL}^S + 6g_{RL}^T)^* - g_{RL}^V(g_{LR}^S + 6g_{LR}^T)^*\Big] ,$$

$$b = 4(|g_{RR}^V|^2 + |g_{LL}^V|^2) + |g_{RR}^S|^2 + |g_{LL}^S|^2 ,$$

$$b' = 4(|g_{RR}^V|^2 - |g_{LL}^V|^2) + |g_{RR}^S|^2 - |g_{LL}^S|^2 ,$$

$$\beta = -4\,\mathrm{Re}\Big[g_{RR}^V(g_{LL}^S)^* + g_{LL}^V(g_{RR}^S)^*\Big] ,$$

$$\beta' = 4\,\mathrm{Im}\Big[g_{RR}^V(g_{LL}^S)^* - g_{LL}^V(g_{RR}^S)^*\Big] ,$$

$$c = \tfrac{1}{2}\Big[|g_{RL}^S - 2g_{RL}^T|^2 + |g_{LR}^S - 2g_{LR}^T|^2\Big] ,$$

$$c' = \tfrac{1}{2}\Big[|g_{RL}^S - 2g_{RL}^T|^2 - |g_{LR}^S - 2g_{LR}^T|^2\Big] .$$

If also the electron mass is neglected, the energy and angular distribution of the electron in the rest frame of a polarized muon ($\mu^\mp$) is given by the Michel spectrum:

$$d^2\Gamma \sim \Big\{3(1-x) + \frac{2\rho}{3}(4x-3) \mp \xi\cos\theta[1 - x + \frac{2\delta}{3}(4x-3)]\Big\}\, x^2 dx\, d(\cos\theta) .$$

Here θ is the angle between the electron momentum and the muon spin, and $x \equiv 2E_e/m_\mu$. For pure V–A coupling, we obtain $\rho = \xi\delta = 3/4$, $\xi = 1$, and the differential decay rate is

$$d^2\Gamma = \frac{G_F^2 m_\mu^5}{192\pi^3}\,[3 - 2x \pm \cos\theta(1-2x)]\, x^2 dx\, d(\cos\theta) .$$

Here the coefficient in front of the square bracket is the total decay rate.

In order to determine the amplitudes $g_{\varepsilon\mu}^\gamma$ uniquely from experiment, Fetscher *et al.* [2] introduced four probabilities $Q_{\varepsilon\mu}(\varepsilon, \mu = R, L)$ for the decay of a μ-handed muon into an ε-handed electron and showed that there exist upper bounds on Q_{RR}, Q_{LR}, and Q_{RL}, and a lower bound on Q_{LL}. These probabilities are given in terms of the $g_{\varepsilon\mu}^\gamma$'s by

$$Q_{\varepsilon\mu} = \frac{1}{4}|g_{\varepsilon\mu}^S|^2 + |g_{\varepsilon\mu}^V|^2 + 3(1 - \delta_{\varepsilon\mu})|g_{\varepsilon\mu}^T|^2 , \qquad (2)$$

where $\delta_{\varepsilon\mu} = 1$ for $\varepsilon = \mu$ and $\delta_{\varepsilon\mu} = 0$ for $\varepsilon \neq \mu$. They are related to the parameters a, b, c, a', b', and c' by

$$Q_{RR} = 2(b+b')/A ,$$

$$Q_{LR} = [(a-a') + 6(c-c')]/2A ,$$

$$Q_{RL} = [(a+a') + 6(c+c')]/2A ,$$

$$Q_{LL} = 2(b-b')/A ,$$

with $A = 16$. In the pure $V-A$ theory, $Q_{LL} = 1$ and the others are zero.

Since the upper bounds on Q_{RR}, Q_{LR}, and Q_{RL} are found to be small, and since the helicity of the ν_μ in pion decay is known from experiment [9,10] to very high precision to be -1 [11], the cross section S of *inverse* muon decay, normalized to the $V-A$ value, yields [2]

$$|g_{LL}^S|^2 \leq 4(1-S) \tag{3}$$

and

$$|g_{LL}^V|^2 = S\ . \tag{4}$$

Thus the Standard Model assumption of a pure $V-A$ leptonic charged weak interaction for e and μ is confirmed (within errors) by experiments at energies far below the mass of the $W^\pm$: Eq. (4) gives a lower limit for $V-A$, and Eqs. (2) and (3) give upper limits for the other four-fermion interactions. The existence of such upper limits may also be seen from $Q_{RR}+Q_{RL} = (1-\xi')/2$ and $Q_{RR}+Q_{LR} = \frac{1}{2}(1+\xi/3-16\xi\delta/9)$. Table 1 gives the current experimental limits on the magnitudes of the $g_{\varepsilon\mu}^\gamma$'s.

Table 1. Ninety-percent confidence level experimental limits for the coupling constants $g_{\varepsilon\mu}^\gamma$. The limits on $|g_{LL}^S|$ and $|g_{LL}^V|$ are from Ref. 12, and the others are from Ref. 13. The experimental uncertainty on the muon polarization in pion decay is included.

$\lvert g_{RR}^S\rvert < 0.066$	$\lvert g_{RR}^V\rvert < 0.033$	$\lvert g_{RR}^T\rvert \equiv 0$
$\lvert g_{LR}^S\rvert < 0.125$	$\lvert g_{LR}^V\rvert < 0.060$	$\lvert g_{LR}^T\rvert < 0.036$
$\lvert g_{RL}^S\rvert < 0.424$	$\lvert g_{RL}^V\rvert < 0.110$	$\lvert g_{RL}^T\rvert < 0.122$
$\lvert g_{LL}^S\rvert < 0.55$	$\lvert g_{LL}^V\rvert > 0.96$	$\lvert g_{LL}^T\rvert \equiv 0$

Limits on the "charge retention" coordinates, as used in the older literature (*e.g.*, Ref. 14), are given by Burkard *et al.* [15].

τ

$J = \frac{1}{2}$

τ discovery paper was PERL 75. $e^+e^- \to \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out $J = 3/2$. KIRKBY 79 also ruled out J=integer, $J = 3/2$.

NOTE ON PROBLEMS IN THE τ-DECAY DATA

(by K.G. Hayes, Hillsdale College)

Problems remain in the experimental data for τ branching ratios. The first evidence that something was wrong was noticed in 1984 in what became known as the "1-prong deficit" [1,2]: If world averages were considered and theoretical predictions were used to limit certain poorly measured modes, then the measured inclusive 1-prong topological branching ratio was significantly larger than the sum of branching ratios of exclusive 1-prong decay modes. Reviews of this problem have appeared in these Listings starting with the 1988 edition. At the time of the 1992 edition, significant discrepancies had appeared between some recent and older measurements of the branching ratios for several modes, most notably $B(h^-2\pi^0\nu_\tau)$ and $B(h^-h^-h^+\nu_\tau)$.

Since the 1992 edition, the situation has changed in two significant ways. The long-standing "tau decay puzzle" has been resolved. If one assumes unitarity, then the leptonic branching ratios ($B_e \equiv B(e^-\overline{\nu}_e\nu_\tau)$ or $B_\mu \equiv B(\mu^-\overline{\nu}_\mu\nu_\tau)$) can be predicted from masses and lifetimes of the muon and tau. Theory and prediction have differed at the 1.5 to 2 standard deviation level since 1986. Since the last edition, new precise measurements have lowered the world averages for the τ mass and lifetime by 1.9 and 1.7 standard deviations, respectively. Using our current world averages for these quantities, the predicted electron branching ratio [3] is $18.11 \pm 0.19\%$, while the world average for $B_e = 17.90 \pm 0.17\%$. This agreement provides strong evidence that the measured leptonic branching ratios of the τ are accurate, and argues against the existence of widespread systematic problems in the various strategies used to derive branching ratios from the observed numbers of $\tau^- \to e^-\overline{\nu}_e\nu_\tau$ and $\tau^- \to \mu^-\overline{\nu}_\mu\nu_\tau$ decays.

The second significant change has resulted from the publication [4,5,6] of precise new branching ratio measurements of τ decay modes of the form $\tau^- \to h^- + (\geq)n\pi^0\nu_\tau$. The CLEO collaboration [5,6] has reported values for $n = 1$, 2, 3, and 4, based upon reconstructed $\pi^0 \to \gamma\gamma$ decays for all π^0's. These new measurements have increased the internal inconsistency of the world data for these modes. The $B(h^-3\pi^0\nu_\tau)$ and $B(h^-4\pi^0\nu_\tau)$ measurements have allowed the replacement of our fit mode $\tau^- \to h^- \geq 3\pi^0\nu_\tau$ by the two new modes $\tau^- \to h^-3\pi^0\nu_\tau$ and $\tau^- \to h^-4\pi^0\nu_\tau$ with the assumption, valid at the present level of precision, that $B(h^- \geq 5\pi^0\nu_\tau)$ is small enough to ignore. A comparison between the current and the 1992 branching ratio fit values for fit modes containing one charged hadron and one or more π^0's is presented in Table 1. The error scale factors from the fit, which are also listed, are all just under two. It is clear that significant discrepancies exist between experimental measurements of these modes.

Table 1: Fit branching ratios (%) and scale factors for τ decay modes containing one charged hadron and one or more π^0's.

Mode	1992 Fit	Scale factor	1994 Fit	Scale factor
$h^-\pi^0\nu_\tau$	24.4 ± 0.6	1.1	25.7 ± 0.4	1.7
$h^-2\pi^0\nu_\tau$	10.3 ± 0.9	1.7	9.6 ± 0.4	1.5
$h^-3\pi^0\nu_\tau$			1.28 ± 0.24	1.7
$h^-4\pi^0\nu_\tau$			$0.19 \pm^{0.12}_{0.10}$	1.7
$h^- \geq 3\pi^0\nu_\tau$	2.7 ± 0.9	1.9	1.48 ± 0.26	1.7

The new measurements have a significant impact on the constrained fit. The fit branching ratios cannot exhibit a problem such as the 1-prong deficit, since the fit 1-prong topological branching ratio is defined to be the sum of branching ratios of exclusive 1-prong modes. Since the set of fit modes sum exactly to one, the fact that the world averages exhibit a 1-prong deficit means that the fit values for some 1-prong modes must be larger than the corresponding average values; many examples are to be found in the present Listings. How much the constraint will increase the fit values above their corresponding averages depends on the errors. In the last two editions, $B(h^-2\pi^0\nu_\tau)$ and $B(h^- \geq 3\pi^0\nu_\tau)$ had relatively large errors, and the fit could account for much of the deficit by increasing these modes with only a small increase in the fit χ^2. For example, the 1992 fit had a χ^2 of 91.8 for 91 degrees of freedom, while the current fit has a χ^2 of 134.6 for 105 degrees of freedom. The large χ^2 is not caused by one or two outlying measurements; the largest single contribution to the χ^2 is 7.0. Table 2 gives the average χ^2 contribution per datum* grouped by decay mode in various ways: all modes used in the fit, modes containing one prong and no neutrals, modes containing one prong plus $\geq 1\pi^0$, and all modes except 1-prong exclusive modes. It is clear that the 1-prong plus $\geq 1\pi^0$ modes contribute the largest amount to the χ^2.

Table 2: Average fit χ^2 contribution of τ branching ratio measurements grouped by decay mode category.

Category	Data entries	$\langle\chi^2\rangle$ per datum
All modes	116	1.17
1-prong 0 neutrals	51	0.74
1-prong $\geq$ 1 neutrals	28	1.87
Not 1-prong modes	37	1.23

The fact that the fit has to spread the branching fraction corresponding to the 1-prong deficit between many relatively well-measured basis modes means that the *average* values for some branching fractions (*i.e.*, B_e and B_μ) may be slightly more accurate than the *fit* values. In this edition, the method of calculating averages has been improved. In previous editions, individual branching fraction measurements were either used for both the fit and averages, or they were excluded from both the fit and averages. Many data must be excluded from the fit because they are highly correlated to other data which are used in the fit. Thus, many data were not used in averages even though there was no other reason to exclude them. With the new change, data not used in the fit may be used in averages. For branching ratios which contain some data which are to be used only in the average, a new column has been added to the Listings to indicate which data are used both for fits and averages ("f&a") and which are flagged for use only for averages ("avg").

Experimental measurements of the charged-prong topological branching fractions† and $B(h^-h^-h^+\nu_\tau)$ also exhibit some internal inconsistency. Refer to the scale factors and ideograms given in the Full Listings for further information.

Conclusions: Experimental measurements of τ branching fractions contain internal inconsistencies. Measurements have become sufficiently precise that the constrained fit to branching ratio data now has an improbably large χ^2. Much of the inconsistency is contained in decay modes of the type $\tau^- \to h^- + (\geq)n\pi^0\nu_\tau$ for $n = 1$, 2, and 3, although the charged-prong topological branching fractions and $B(h^-h^-h^+\nu_\tau)$ also show signs of problems. Future precise measurements at LEP should resolve the problems in the charged-prong topological branching fractions. Additional measurements with small, well-understood systematic errors are needed to sort out the confusion in the other modes.

Notes and References

* Because of the way we have grouped the modes, the number of degrees of freedom (dof) is not available except for the "all modes" category. While not as well defined as χ^2 per dof, the number provides a useful measure of the source of the dominant χ^2 contributions.

† We have slightly generalized the idea of topological branching fractions to include $(\geq)n\pi^0$'s. These are *topological*, in the sense that they classify what is observed, rather than *physical*, which would classify modes at the top of the decay chain: e, μ, π, K, ρ, $K^*(892)$, *etc.*

[1] BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \to \tau^+\tau^- \to (\pi^+ n\pi^0\nu_\tau)(\pi^- m\pi^0\nu_\tau)$ $n \leq 2$, $m \leq 2$, $1 \leq n+m \leq 3$. If $m_{\nu_\tau} \neq 0$, result increases by $(m^2_{\nu_\tau}/1100$ MeV).

[2] ALBRECHT 92M fit τ pseudomass spectrum in $\tau^- \to 2\pi^-\pi^+\nu_\tau$ decays. Result assumes m_{ν_τ}=0.

[3] BAI 92 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ near threshold using $e\mu$ events.

[4] BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

[5] BARTEL 78 fits energy dependence of cross section for $e^\pm$ and $\mu^\pm$ events. Mass value not dependent on whether $V-A$ or $V+A$ decay assumed.

τ MEAN LIFE

The downward revision of the τ mass to 1777.1 MeV (see the τ mass above) results in a downward correction of some of the older lifetime measurements, with the net result that the average should be reduced by 0.2 fs. WASSERBAECH 93 shows that additional systematic biases are not consistently taken into account by the experimenters. When the appropriate corrections are applied, the average is decreased by an additional 0.8 fs. "OUR EVALUATION" reflects these changes.

[a] ℓ means a sum over e and μ modes.

[b] The value is for the sum of the charge states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 30 branching ratios uses 116 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 134.4$ for 105 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

NOTE ON τ-DECAY BRANCHING FRACTIONS

(by K.G. Hayes, Hillsdale College, and D.E. Groom, LBL)

The goal in making fits to the experimental measurements of τ branching ratios is to get "best estimates" of the branching fractions. For a constrained fit, it is necessary to define a set of exclusive basis modes whose branching fractions sum exactly to unity. In principle, one would choose the modes at the top of the decay chain as the basis modes: e, μ, π, K, ρ, $K^*(892)$, a_1, ρ', *etc.*, as well as states involving more than one of these particles. Since experimental data do not yet allow this, a compromise has to be made between clean theoretical modes and the quantities that are actually measured.

Historically, experiments have distinguished electrons, muons, charged hadrons, and "neutrals;" that is, electromagnetic activity presumed to be the result of π^0 decay. Older papers reported the charged hadrons as $\pi^\pm$, but this is no longer sufficient, given present precision. Newer experiments are also providing good π^0 reconstruction and good vertex reconstruction. Most papers still report the nonleptonic modes as "m charged hadrons + $(\geq)n\pi^0$'s," where $m = 1, 3$, or 5.

Charged-prong topological branching modes (1-, 3-, or 5-charged-prong events) remain important, although only the 5-prong mode survives as one of our basis modes. However, we have slightly generalized the idea of topological branching fractions to include $(\geq)n\pi^0$'s. These are *topological*, in the sense that they classify what is observed, rather than *physical*, which would classify the modes at the top of the decay chain.

The basis modes are chosen to reflect the state of the art, and hence evolve with the data. For this edition, we use 12 basis modes:

$e^-\overline{\nu}_e\nu_\tau$	$K^*(892)^-\nu_\tau$	$h^-4\pi^0\nu_\tau$
$\mu^-\overline{\nu}_\mu\nu_\tau$	$\pi^-\pi^0\nu_\tau$	$2h^-h^+\nu_\tau$
$\pi^-\nu_\tau$	$h^-2\pi^0\nu_\tau$	$2h^-h^+ \geq 1$ neutrals ν_τ
$K^-\nu_\tau$	$h^-3\pi^0\nu_\tau$	$3h^-2h^+ \geq 0$ neutrals ν_τ

(Charge conjugate states are assumed, and $h^{\pm}$ indicates a $\pi^{\pm}$ or $K^{\pm}$.) The $K^*(892)$ is the only resonance included because the $\tau^- \to K^*(892)^-\nu_\tau$ and $K^*(892)^-$ branching fractions are very well measured. By comparison, the $\pi^-\pi^0\nu_\tau$ mode is predominantly $\rho^-\nu_\tau$, but also includes $\rho'^-\nu_\tau$ and any nonresonant component.

Kaons present several of special problems at the 0.5% level, whether they come directly from τ^- decay or from the decay of an intermediate K^*. This comes about for several reasons:

(a) Most experiments lack charged particle identification, and hence our basis modes of the form "m charged hadrons + $(\geq)n\pi^0$'s" must include directly produced kaons but exclude those from $K^*(892)$ decay.

(b) K_L's are usually undetected.

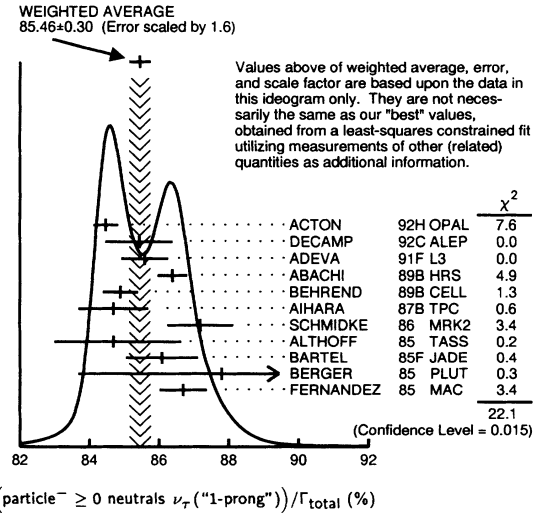
(c) $K_S \to \pi^+\pi^-$ causes confusion even for the topological branching ratios, since it is only recently that they can be sorted out with practical efficiency. Even so, branching ratios to final states containing K_S's (exclusive of those with an intermediate $K^*(892)$) are poorly known. For the moment, events containing such decays are counted with the 3-prong modes.

Experimenters often make corrections for various kaon backgrounds. Because of our present definition of the basis modes, the *only* background defined in our Listings for the "m charged hadrons + $(\geq)n\pi^0$'s" modes are the contributions from $K^*(892)$ decay. Thus, all results must be corrected for the different assumptions that the experimenters made about background definitions, at least to the degree that they are documented in the papers. The $K^*(892)^-$ branching fractions to the final states are as follows:

$$
\begin{array}{lll}
K^*(892)^- \to K^-\pi^0 & & 1/3 \\
\quad \hookrightarrow K^0\pi^- \to K_L\pi^- & & 1/3 \\
\quad\quad \hookrightarrow K_S\pi^- \to \pi^-\pi^+\pi^- & & 0.2286 \\
\quad\quad\quad \hookrightarrow \pi^-\pi^0\pi^0 & & 0.1046
\end{array}
$$

These branching fractions appear throughout the listings. For example, the topological 1-prong mode includes 0.771 $B(K^*(892)^-\nu_\tau)$ (since $1/3 + 1/3 + 0.1046 = 0.7712$), while the 3-prong fraction includes the remaining 0.229 $B(K^*(892)^-\nu_\tau)$. Similarly, $B(h^-\nu_\tau) = B(\pi^-\nu_\tau) + B(K^-\nu_\tau) + \frac{1}{3}B(K^*(892)^-\nu_\tau)$ because of the unseen K_L's, and $B(h^-\pi^0\nu_\tau) = B(\pi^-\pi^0\nu_\tau) + \frac{1}{3}B(K^*(892)^-\nu_\tau)$ because of the $K^-\pi^0$ final states from $K^*(892)^-$ decay.

The present basis mode definitions contain many inconsistencies at the few tenths of a percent level. In principle, the above examples should contain contributions from $\pi^-K_L\overline{K}_L$, $K^-\overline{K}_L$, nonresonant $(\pi K)^-$ states, *etc.* We also define $B(h^- \geq 3\pi^0\nu_\tau)$ as the sum of states containing 3 π^0's and 4 π^0's, neglecting those with 5 or more neutral pions. Hopefully, these inconsistencies enter at levels well below the uncertainties of present experiments. The set of basis modes is under constant reevaluation, and in fact has been changed in each of our last three editions. Revision will continue, as better detectors record larger numbers of τ decays with better-understood systematics. Perhaps one day most events containing $K_S \to \pi^+\pi^-$ will be classified as 1-prong events, and high-quality older results will be corrected accordingly.



τ^- BRANCHING RATIOS

$\Gamma(\text{particle}^- \geq 0 \text{ neutrals } \nu_\tau(\text{"1-prong"}))/\Gamma_{\text{total}}$
$\Gamma_1/\Gamma = (\Gamma_2+\Gamma_4+\Gamma_7+\Gamma_9+\Gamma_{13}+\Gamma_{16}+\Gamma_{18}+\Gamma_{19}+0.771\Gamma_{41})/\Gamma$

The charged particle here can be e, μ, or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below. The measurements used only for the average are marked "avg," whereas "f&a" marks a result used for the fit and the average.

6.1 ±0.8 ±0.9			[71] BURCHAT	87	MRK2	E_{cm}^{ee} = 29 GeV

[66] BEHREND 90 value is not independent of BEHREND 90 B($3h\nu_\tau \geq 1$ neutrals) + B(5-prong).

[67] ALBRECHT 87L measure the product of branching ratios B($3\pi^\pm\pi^0\nu_\tau$) B($(e\overline{\nu}$ or $\mu\overline{\nu}$ or π or K or $\rho)\nu_\tau$) = 0.029 and use the PDG 86 values for the second branching ratio which sum to 0.69 ± 0.03 to get the quoted value.

[68] Contributions from kaons and from $>1\pi^0$ are subtracted. Not independent of (3-prong + $0\pi^0$) and (3-prong + $\geq 0\pi^0$) values.

[69] Value obtained using paper's R = B($h^-h^-h^+\nu_\tau$)/B(3-prong) and current B(3-prong) = 0.143.

[70] Not independent of SCHMIDKE 86 $h^-h^-h^+\nu_\tau$ and $h^-h^-h^+(\geq 0\pi^0)\nu_\tau$ values.

[71] BURCHAT 87 value is not independent of SCHMIDKE 86 value.

$\Gamma((a_1(1260)\pi)^-\nu_\tau)/\Gamma(\pi^-\pi^-\pi^+\pi^0\nu_\tau)$ Γ_{24}/Γ_{23}

τ DECAY PARAMETERS

NOTE ON τ-DECAY PARAMETERS

Neglecting radiative corrections and terms proportional to m_ℓ^2/m_τ^2, the energy spectrum of the charged decay lepton ℓ in the τ rest frame is given by

$$\frac{d^2\Gamma_{\tau\to\ell\nu\bar{\nu}}}{d\Omega\,dx}\propto x^2$$
$$\times\left\{12(1-x)+\rho_\tau\left(\frac{32}{3}x-8\right)+24\eta_\tau\frac{m_\ell}{m_\tau}\frac{(1-x)}{x}\right.$$
$$\left.-P_\tau\xi_\tau\cos\theta\left[4(1-x)+\delta_\tau\left(\frac{32}{3}x-8\right)\right]\right\}. \qquad (1)$$

Here $x=2E_\ell/m_\tau$ is the scaled lepton energy, P_τ is the τ polarization, and θ is the angle between the τ spin and the lepton momentum. With unpolarized τ's or integrating over the full θ range, the spectrum depends only on ρ_τ and η_τ. Measurements of the other two Michel parameters, ξ_τ and δ_τ, require polarized τ's. Where possible, we give separately the parameters for $\tau^-\to e^-\nu_\tau\bar{\nu}_e$ and $\tau^-\to\mu^-\nu_\tau\bar{\nu}_\mu$, to avoid assumptions about universality.

ρ^τ(e or μ) PARAMETER

Number of Light Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2)×U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m_\nu \ll m_{Z^0}$. The limits are on the number of neutrino families or species, including ν_e, ν_μ, ν_τ

NOTE ON THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

(by Dean Karlen, Carleton University)

The most precise measurements of the number of light neutrino types, N_ν, come from studies of Z production in e^+e^- collisions. At the time of this report, the most recent combined analysis of the four LEP experiments [1] included nearly 8 million visible Z decays. The invisible partial width, Γ_{inv}, is determined from these data by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to N_ν light neutrino species each contributing the neutrino partial width Γ_ν as given by the

Standard Model. The Standard Model value for Γ_ν, however, is uncertain by about 1% due to the unknown top quark mass. In order to reduce this uncertainty, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_\nu/\Gamma_\ell)_{SM} = 1.992 \pm 0.003$, is used instead to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{inv}}{\Gamma_\ell}\left(\frac{\Gamma_\ell}{\Gamma_\nu}\right)_{SM}$$

The combined LEP result is $N_\nu = 2.985 \pm 0.023 \pm 0.004$, where the first error is the combined statistical and systematic uncertainty and the second is the uncertainty from allowing the top quark mass to vary between 100 and 200 GeV.

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_ν was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is much more dependent on the Standard Model and the top quark mass, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \to \nu\bar{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of $N_\nu < 4.8$. This process has since been measured at LEP by the ALEPH, L3, and OPAL experiments [3], and the combined result is $N_\nu = 2.97 \pm 0.17$.

Experiments at $p\bar{p}$ colliders also placed limits on N_ν by determining the total Z width from the observed ratio of $W^\pm \to \ell^\pm\nu$ to $Z \to \ell^+\ell^-$ events [5]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

[1] Simultaneous fits to all measured Z data.
[2] Analysis based on $\geq$ 1.1 million visible Z decays from LEP runs through 1992.
[3] These papers assume standard model couplings.
[4] Simultaneous fits to all measured cross section data from all four LEP experiments.
[5] Second error is from uncertainty in top and Higgs mass.
[6] These papers measure leptonic widths and are more model independent. However, they divide the measured invisible width via the Standard Model width for neutrinos. Such results are less precise, as discussed in the minireview.
[7] The second error is due to theoretical uncertainties.

Number of Light ν Types from Direct Measurement of Invisible Z Width

In the following, the invisible Z width is obtained from studies of single-photon events from the reaction $Z \to \nu\bar{\nu}\gamma$. All are obtained from LEP runs in the E_{cm}^{ee} range 88–94 GeV.

Heavy Lepton Searches

NOTE ON HEAVY LEPTON SEARCHES

Data on the $\tau^{\pm}$ are listed in a separate section, following the e and μ listings. Data on excited leptons (e^*, μ^*, τ^*) appear in the section "Searches for Quark and Lepton Compositeness." Searches for fractionally charged heavy leptons are included in the section on "Free Quark Searches."

The following section contains information on searches for heavy leptons of other types.

Several types of heavy leptons (that is, non-strongly-interacting fermions other than e and μ) have been proposed. In the Full Listings, following a historical practice specific to this area, we distinguish four types [1]. Each has a corresponding antiparticle with opposite charge and lepton number. For convenience we omit writing the antiparticles in the following descriptions. The four types are:

Sequential leptons (L^-, ν_L). Such a pair has often been assumed to have its own separately strictly conserved lepton number $n_L = +1$. Such a conservation law means that the radiative decays

$$\left.\begin{aligned} L^- &\to e^-\gamma \\ L^- &\to \mu^-\gamma \\ L^- &\to \tau^-\gamma \end{aligned}\right\} \text{ are forbidden ,}$$

while the weak decays (assuming m_{L^-} sufficiently large)

$$\left.\begin{aligned} L^- &\to \nu_L e^- \overline{\nu}_e \\ L^- &\to \nu_L \mu^- \overline{\nu}_\mu \\ L^- &\to \nu_L \tau^- \overline{\nu}_\mu \\ L^- &\to \nu_L \; hadrons \end{aligned}\right\} \text{ are allowed .}$$

There could be an increasing mass sequence of such pairs. It is frequently assumed that the neutrinos are massless (a natural concomitant of the L number conservation law).

Decay rates are assumed to be calculable from conventional weak interaction theory. For example, for an L^- mass between 1 GeV and 3 GeV, the branching fraction to each of the two leptonic modes above should be roughly 10% to 20%. For an L^- mass above 1 GeV, the mean life should be $\lesssim 10^{-12}$ second.

Paraleptons (e_P^+, e_P^0), (μ_P^+, μ_P^0), (τ_P^+, τ_P^0). The lepton number of (e_P^+, e_P^0) is the same as that of (ν_e, e^-), and similarly for the other paraleptons. Radiative decays are again forbidden, and decays similar to those allowed for L^- are allowed here, *e.g.*,

$$\mu_P^+ \to \nu_\mu e^+ \nu_e$$

$$\mu_P^+ \to \nu_\mu \mu^+ \nu_\mu$$

$$\mu_P^+ \to \nu_\mu \; hadrons \; .$$

However, the lightest member is not stable as is the case for sequential leptons, so that bizarre decay schemes such as

$$e_P^+ \to e_P^0 \mu^+ \nu_\mu$$
$$\qquad\quad \hookrightarrow e^- e^+ \nu_e$$

(assuming $m_{e_P^0} < m_{e_P^+}$) are allowed. Occasional searches have been made for doubly-charged paraleptons.

Before the discovery of the Z boson, heavy leptons of this type were proposed in unified gauge theories of weak and electromagnetic interactions to cancel unphysical high-energy behavior in such processes as $e^+e^- \to W^+W^-$ [2]. The theoretical motivation disappeared with the discovery of neutral currents and confirmation of the standard electroweak theory. However, from a purely phenomenological viewpoint, it is still of interest to search for paraleptons.

Ortholeptons (e_O^-, μ_O^-, τ_O^-). These are defined as having the same lepton numbers as the corresponding regular leptons. The quantum numbers of an ortholepton are thus essentially equivalent to those of an excited lepton. Historically, the emphasis in the excited leptons has been on the radiative decay mode, and the connection with compositeness, whereas the ortholepton denotation has been a more general category. Reflecting this, we list limits on excited leptons in the section on compositeness. Ortholeptons may or may not have associated neutral leptons. Both radiative decays and regular weak decays similar to those of sequential leptons can occur.

Long-lived penetrating particles. Heavy leptons could have long mean lives under certain circumstances. For example, if $m_{\nu_L} > m_{L^-}$, then L^-, the sequential lepton, would only be able to decay via lepton mixing and could have a relatively long lifetime.

Perl's review [3] gives further details.

Limits apply only to heavy lepton types specified. See review above for description of types. $L, e_P, \mu_P, \tau_P, e_O, \mu_O$, and τ_O denote sequential lepton, para-electron, para-muon, para-tau, ortho-electron, ortho-muon, and ortho-tau, respectively. As noted, limits for excited leptons (e^*, μ^*, τ^*) are included in the section on "Searches for Quark and Lepton Compositeness."

Charged Heavy Lepton MASS LIMITS

Sequential Charged Heavy Lepton ($L^\pm$) MASS LIMITS

These experiments assumed that a fourth generation $L^\pm$ decayed to a fourth generation ν_L (or L^0) where ν_L was stable. New data show that stable ν_L have $m_{\nu_L} > 42.7$ GeV so that the above assumption is not valid for any mass limit $\lesssim 42.7$ GeV. One can instead assume that $L^\pm$ decays via mixing to ν_e, ν_μ and/or ν_τ, and in that context the limits below are meaningful.

[1] RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-} - m_{L^0}$ was allowed to be quite small, where L^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced $m_{L^\pm}$ range, the mass difference extends to about 4 GeV.

[2] STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L^+) mass for the generalized case in which the corresponding neutral heavy lepton (L^0) in the SU(2) doublet is not of negligible mass.

[3] ABE 88 search for L^+ and L^- → hadrons looking for acoplanar jets. The bound is valid for $m_\nu < 10$ GeV.

[4] ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}{}^{ee} = 52$ GeV.

[5] IGARASHI 88 search for multi-hadron events with isolated leptons. $E_{cm}{}^{ee} = 50$–52 GeV.

[6] KIM 88 search for $L^\pm$ → hadrons with $L^\mp$ → isolated lepton X and for $L^\pm$ and $L^\mp$ → hadrons. $E_{cm}{}^{ee} = 56$ GeV.

[7] Assumes associated neutrino is approximately massless.

[8] ADEVA 85 analyze one-isolated-muon data and sensitive to τ <10 nanosec. Assume B(lepton) = 0.30. $E_{cm} = 40$–47 GeV.

[9] ADEVA 83B looked for muon opposite against a hadron jet.

[10] BARTEL 83 limit is from PETRA e^+e^- experiment with average $E_{cm} = 34.2$ GeV.

[11] BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[12] BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[13] AZIMOV 80 estimated probabilities for $M + N$ type events in $e^+e^- \to L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{cm} = (2/3)m_L$. Obtained above limit comparing these with e^+e^- data (BRANDELIK 80).

[14] BARBER 80B looked for $e^+e^- \to L^+L^-$, $L \to \nu_L^+ X$ with MARK-J at DESY-PETRA.

[15] ROTHE 69 examines previous data on μ pair production and π and K decays.

[17] BACCI 77B is same type as BACCI 73. Lower mass limit corresponds to λ^2 limit of 4×10^{-5}, upper value is for λ^2 limit of 1.5×10^{-3}.

[18] BACCI 73 is Frascati e^+e^- experiment. Looks for $e_O \to e\gamma$. Mass limit depends on coupling constant λ for this decay. First value above is for $\lambda^2 > 9 \times 10^{-5}$, second is for $\lambda^2 > 10^{-3}$.

[19] LICHTENSTEIN 70 is Cornell experiment measuring e Bremsstrahlung. Mass limit depends on coupling constant. First value above is for $\lambda^2 > 0.17$, second is for $\lambda^2 > 0.42$.

[20] BOLEY 68 is CEA experiment. Looks for $ep \to e_O p$. Mass of 0.1 corresponds to coupling constant $\lambda^2 > 3 \times 10^{-4}$, mass limit of 1.3 to $\lambda^2 > 0.01$.

[21] BUDNITZ 66 is CEA experiment. Looks for $ep \to e_O p$.

[22] BEHREND 65 is DESY experiment. Looks for $ep \to e_O p$, $e_O \to e\gamma$. This mass limit corresponds to a limit on λ^2 of 6.25×10^{-4}.

[23] BETOURNE 65 is Orsay experiment. Looks for $ep \to e_O p$. Mass of 0.12 corresponds to coupling constant $\lambda^2 > 0.0016$, mass of 0.57 to $\lambda^2 > 0.22$.

Charged Ortho-Muon ($\mu_O^\pm$) MASS LIMITS

See also the section "MASS LIMITS for Excited μ" in the section on "Searches for Quark and Lepton Compositeness."

none 0.2–0.6			[28] LIBERMAN	69	OSPK	–

[24] ASRATYAN 78 analyzes dependence of (neutral current/charged current) on energy of associated hadrons. Uses data of HOLDER 77 — ν_μ interactions at CERN-SPS.

[25] CNOPS 78 is FNAL experiment looking for $\nu_\mu \text{Ne} \to L^\pm$, followed by $L^\pm \to e^\pm \nu\nu$.

[26] ASRATYAN 74 uses EICHTEN 73 data on νnucleon → e^-hadrons and $\bar{\nu}$nucleon → e^+hadrons to set limits on orthomuon production.

[27] GITTLESON 74 is $\mu p \to p \mu_O$ search. Coupling constant λ^2 is <0.01 for mass up to 0.7 GeV, limit on λ^2 rises to <0.1 for mass of 2.0 GeV.

[28] LIBERMAN 69 is a BNL experiment measuring muon Bremsstrahlung.

Charged Para-Muon ($\mu_P^\pm$) MASS LIMITS

[29] CNOPS 78 is FNAL experiment looking for $\nu_\mu \text{Ne} \to L^\pm$, followed by $L^\pm \to e^\pm \nu\nu$.

[30] ERRIQUEZ 78 is CERN SPS experiment. Looks for ν_μ nucleon → $\mu^- e^+ X$. Finds cross section for producing heavy lepton → $e^+ < 0.7 \times 10^{-3} \times$CC cross section.

[31] HOLDER 78 is a CERN ν experiment looking for ν_μ nucleon → μ^+ anything. Assumes $\mu_P^+ \to \mu^+ 2\nu_\mu$ with BR = 0.2.

[32] BARISH 74 is FNAL 50,135 GeV ν experiment. Looks for (νnucleon → $\mu_P^+ X$). Assumes ($\mu_P^+ \to \mu^+ \nu_\mu \nu_\mu$) with BR = 0.3.

[33] BARISH 73B is FNAL 50,145 GeV ν experiment. Looks for (νnucleon → $\mu_P^+ X$). Assumes ($\mu_P^+ \to \mu^+ \nu_\mu \nu_\mu$) with BR = 0.3.

[34] EICHTEN 73 is CERN 1–10 GeV ν experiment. Looks for μ_P^+ produced in νnucleon → μ_P^+hadrons assuming 15% decay to $e^+ \nu_\mu \nu_e$.

[40] ADRIANI 92I is a search for isosinglet heavy lepton N_ℓ which might be produced from $Z \to \nu_\ell N_\ell$, then decay via a number of different channels. Limits are weaker for decay lengths longer than about 1 m.

[41] ADEVA 90S limits for the heavy neutrino apply if the mixing with the charged leptons satisfies $|U_{1j}|^2 + |U_{2j}|^2 + |U_{3j}|^2 > 6.2\times10^{-8}$ at $m_{L^0} = 20$ GeV and $> 5.1\times10^{-10}$ for $m_{L^0} = 40$ GeV.

[42] AKRAWY 90L limits valid if coupling strength is greater than a mass-dependent value, e.g., 4.9×10^{-7} at $m_{L^0} = 20$ GeV, 3.5×10^{-8} at 30 GeV, 4×10^{-9} at 40 GeV.

[43] Limits apply for $\ell = e$, μ, or τ and for $V-A$ decays of Dirac neutrinos.

[44] BURCHAT 90 searched for Z decay to unstable L^0 pairs at SLC. It includes the analyses reported in JUNG 90, ABRAMS 89C, and WENDT 87.

[45] For $25 < m_{L^0} < 42.7$ GeV, DECAMP 90F exclude an L^0 for all values of $|U_{\ell j}|^2$.

[46] ABREU 92B limit is for mixing matrix element ≈ 1 for coupling to e or μ. Reduced somewhat for coupling to τ, increased somewhat for smaller mixing matrix element. Replaces ABREU 91F.

[47] SHAW 89 also excludes the mass region from 8.0 to 27.2 GeV for Dirac L^0 and from 8.1 to 23.6 GeV for Majorana L^0 with equal full-strength couplings to e and μ. SHAW 89 also gives correlated bounds on lepton mixing.

[48] AKERLOF 88 is PEP e^+e^- experiment at $E_{cm} = 29$ GeV. The L^0 is assumed to decay via $V-A$ to e or μ or τ plus a virtual W.

[49] The first bound of BEHREND 88C applies for a general L^0. The second and third have their assumptions indicated.

[50] MISHRA 87 is Fermilab neutrino experiment looking for either dimuon or double vertex events (hence long-lived).

[51] WENDT 87 is MARK-II search at PEP for heavy ν with decay length 1–20 cm (hence long-lived).

[52] BADIER 86 is a search for a long-lived penetrating sequential lepton produced in π^- – nucleon collisions with lifetimes in the range from $5. \times 10^{-7}$–$5. \times 10^{-11}$ s and decaying into at least two charged particles. U_{ej} and U_{mj} are mixing angles to ν_e and ν_μ. See also the BADIER 86 entry in the section "Searches for Massive Neutrinos and Lepton Mixing".

[53] BARTEL 83 is PETRA e^+e^- experiment with average $W_{cm} = 34.2$ GeV. First (second) limit is for $V+A(V-A)$ type $W^- e_P e$ coupling.

[54] CLARK 81 is FNAL experiment with 209 GeV muons. Bounds apply to para-muon which couples with full weak strength to muon. See also section on "Neutral Heavy Lepton Production Cross Section (μ Nucleon)" below.

[55] Limits based on annihilations in the sun and are due to an absence of high energy neutrinos detected in underground experiments.

[56] MORI 92B results assume that neutrinos make up dark matter in the galactic halo. Limits based on annihilations in earth are also given.

[57] REUSSER 91 uses existing $\beta\beta$ detector (see FISHER 89) to search for CDM Dirac neutrinos.

[58] ENQVIST 89 argue that there is no cosmological upper bound on heavy neutrinos.

[59] These results assume that neutrinos make up dark matter in the galactic halo.

Searches for Massive Neutrinos and Lepton Mixing

Searches for the effects of nonzero neutrino masses are listed here. Direct searches for masses of dominantly coupled neutrinos are listed in the appropriate section on ν_e, ν_μ, or ν_τ. The results in the present section are correlated upper bounds on mixing matrix coefficients U_{aj} versus neutrino mass. These results are divided into three main sections:

1. Bounds from particle and nuclear decays;
2. Bounds from neutrino reactions, including reactor and accelerator neutrino oscillation experiments, and solar neutrino measurements (see the "Note on Neutrino Oscillations" below); and
3. Searches for neutrinoless double-β decay:

Discussion of the ν_e and ν_μ mass limits, the "17 keV neutrino," and solar neutrino observations are given in the "Note of Neutrinos" by R.E. Shrock in the ν_e section near the beginning of these data listings. Several reviews are also listed there. See also the "Note on the Muon Neutrino Mass" before the ν_μ Listings.

In addition, searches for mixing of (μ^-e^+) and (μ^+e^-) are given in the muon Listings.

[7] BARANOV 93 is a search for neutrino decays into $e^+e^-\nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.
[8] BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89C, and WENDT 87.
[9] OBERAUER 87 bounds from search for $\nu \to \nu' e e$ decay mode using reactor (anti)neutrinos.
[10] COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_τ flux. We do not list these. Note that for this bound to be nontrivial, j is not equal to 3, i.e. ν_j cannot be the dominant mass eigenstate in ν_τ since m_{ν_3} <70 MeV (ALBRECHT 85I). Also, of course, j is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.
[11] BERGSMA 83B also quote limits on $|U_{13}|^2$ where the index 3 refers to the mass eigenstate dominantly coupled to the τ. Those limits were based on assumptions about the D_s mass and $D_s \to \tau\nu_\tau$ branching ratio which are no longer valid. See COOPER-SARKAR 85.

[12] ABELE 93: "It appears to us that we have succeeded in isolating experimentally the very same effect that was proposed in HIME 93 to resolve the '17 keV condrum'."

[13] BERMAN 93 uses an iron-free intermediate-image magnetic spectrometer to measure ^{35}S β decay over a large portion of the spectrum. Paper reports (0.01 ± 0.15)%; above result revised by author on basis of analysis refinements.

[14] DIGREGORIO 93 is an experiment on ^{71}Ge IBEC to search for a possible admixture of a massive neutrino. The authors state that their results "exclude the presence of a massive component of 17.2 ± 1.3 ± 1.1 keV and (1.6 ± 0.6)% mixing fraction claimed by [ZLIMEN 91] for this same nucleus, at the 99.0% confidence level."

[15] HIME 93 is a reanalysis of HIME 91 data and states that the effect, which was previously attributed to the emission of a massive neutrino, can be explained by electron energy loss without the need for any neutrino mass or mixing.

[16] KALBFLEISCH 93 extends the 17 keV neutrino search of BAHRAN 92, using an improved proportional chamber to which a small amount of ^{3}H is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on $|U_{1j}|^2$ as a function of m_{ν_j} in the range from 13.5 keV to 17.5 keV. Typical upper limits are listed above. They report that this experiment in combination with BAHRAN 92 gives an upper limit of 2.4×10^{-3} at the 99% CL. See also the related papers BAHRAN 93 and BAHRAN 93B, on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.

[17] MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that "The sensitivity to neutrino mass is verified by measurement with a mixed source of ^{35}S and ^{14}C, which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino."

[18] OHSHIMA 93 is the full data analysis from this experiment. The above limit on the mixing strength for a 17 keV neutrino is obtained from the measurement $|U_{1j}|^2 = (-0.11 \pm 0.33 \pm 0.30) \times 10^{-3}$ by taking zero as the best estimate and ignoring physical boundaries; see discussion in HOLZSCHUH 92B for a comparison of methods. Using the Particle Data Group recipe gives the slightly more conservative 95%CL of 0.80×10^{-3}. An earlier report of this experiment was given in KAWAKAMI 92.

[19] WIETFELDT 93 is an extension of the NORMAN 91 experiment. However, whereas NORMAN 91 reported indications for the emission of a neutrino with mass $m_{\nu_j} = 21 \pm 2$ keV and coupling strength = 0.0085 ± 0.0045, the present experiment states that "We find no evidence for emission of a neutrino in the mass range 5–25 keV. In particular, a 17 keV neutrino with $\sin^2\theta$ ($|U_{1j}|^2$ in our notation) = 0.008 is excluded at the 7σ level." The listed limits can be obtained from the paper's Fig. 4. The authors acknowledge that this conclusion contradicts the one reported in NORMAN 91, based on a smaller data sample.

[20] BAHRAN 92 minor errors corrected in BAHRAN 92B.

[21] CHEN 92 is a continuation and improvement of the Boehm *et al.* Caltech iron-free magnetic spectrometer experiment searching for emission of massive neutrinos in ^{35}S decay (MARKEY 85). The upper limit on $|U_{1j}|^2$ for $m_{\nu_j} = 17$ keV comes from the measurement $|U_{1j}|^2 = (-0.5 \pm 1.4) \times 10^{-3}$. The authors state that their results "rule out, at the 6σ level, a 17 keV neutrino admixed at 0.85% (*i.e.* with $|U_{1j}|^2 = 0.85 \times 10^{-2}$," the level claimed by Hime and Jelly in HIME 91. They also state that "our data show no evidence for a heavy neutrino with a mass between 12 and 22 keV" with substantial admixture in the weak admixture in the weak eigenstate ν_e; see their Fig. 4 for a graphical set of measured values of $|U_{1j}|^2$ for various hypothetical values of m_{ν_j} in this range.

[22] KAWAKAMI 92 experiment final results are given in OHSHIMA 93. The upper limit is improved to 0.73×10^{-3}, based on $|U_{1j}|^2 = (-0.11 \pm 0.33 \pm 0.30) \times 10^{-3}$. Ohshima notes that the result is 22σ away from the value $|U_{1j}|^2 = 1\%$.

[23] SUR 91 reports an LBL experiment using a solid state Ge crystal grown with ^{14}C inside. In a conference report (NORMAN 91), the authors also report indications for the emission of a 17 keV neutrino in the ^{55}Fe inner bremsstrahlung transition: $m_{\nu_j} = 21 \pm 2$ keV with $|U_{1j}|^2 = 0.0085 \pm 0.0045$.

[24] ZLIMEN 91 used a HPGe detector to observe the inner bremsstrahlung electron capture transition of ^{71}Ge in an external source. Reported errors on both parameters are given as 95%CL limits, which in the case of normal distributions corresponds to 1.96σ.

[25] DRUKAREV 89 claims that taking into account screening effects can explain Simpson's claims without invoking a massive neutrino or other unconventional physics. A similar criticism concerning screening corrections had been made by LINDHARD 86.

[26] HIME 89 corrects the analysis of the data of SIMPSON 85 for screening effects as suggested by LINDHARD 86, giving a smaller range for $|U_{1j}|^2$, as cited above. This value should therefore replace that given in SIMPSON 85, which has been retracted.

[27] SIMPSON 89 and HIME 89 report kinks due to the emission of a massive neutrino in ^{35}S and ^{3}H β decays, respectively.

[28] ZLIMEN 88 report an experiment on ^{55}Fe, observing internal bremsstrahlung in electron capture (IBEC). For a contemporary review of IBEC, see LOGAN 89.

[29] HETHERINGTON 87 reports no evidence for any massive neutrino signal for m_{ν_j} in the range from 4 to 40 keV, and, in particular, set the upper limit cited above on $|U_{1j}|^2$ for a hypothetical 17 keV neutrino.

[30] BORGE 86 results originally presented as evidence against the SIMPSON 85 claim of a 17 keV antineutrino emitted with $|U_{1j}|^2 = 0.03$ in ^{3}H decay.

[31] SIMPSON 86 is a reanalysis of the OHI 85 data and claims that these data show evidence of heavy neutrino emission with $m_{\nu_j} = 17$ keV and $|U_{1j}|^2$ = from 0.01 to 0.02, consistent with the earlier reported observation by SIMPSON 85. This conclusion strongly disagrees with the conclusion reached by OHI 85 from their analysis of their own data. SIMPSON 86 also states that "a similar threshold effect (due to supposed heavy neutrino emission) is seen in several of the other published ^{35}S experiments as well."

[32] This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of 1.7×10^{-3} at CL = 90%.

[33] SIMPSON 85. See footnotes on SIMPSON 89 and SIMPSON 86, as well as comments by HAXTON 85, KALBFLEISCH 85, EMAN 86, LINDHARD 86, DRUKAREV 86, and further discussion by SIMPSON 89 and HIME 89.

[34] SCHRECKENBACH 83 is a combined measurement of the β^+ and β^- spectrum.

[35] SHROCK 80 was a retroactive analysis of data on several superallowed β decays to search for kinks in the Kurie plot.

[36] CONWAY 59 first reported a spectral excess of about 1% at electron kinetic energy of 1 keV in ^{3}H β decay, but did not interpret it as the emission of a massive neutrino. Indeed, no searches for masses admixed neutrinos were performed prior to 1980; cf. SHROCK 80. This spectral excess was again observed in SIMPSON 85, apparently without knowledge of the CONWAY 59 finding. Spectral excesses in this kinetic energy region were also reported in HAMILTON 58 and JOHNSON 58, and in other references cited therein.

[47] BARANOV 93 is a search for neutrino decays into $e^+e^-\nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron.

(B) Bounds from ν Reactions

NOTE ON NEUTRINO OSCILLATION EXPERIMENTS

Experimental results on neutrino oscillations are often presented as allowed regions on a plot of $|\Delta m^2|$ as a function of $\sin^2 2\theta$, where $\Delta m^2 = m^2_{\nu_i} - m^2_{\nu_j}$. Although there are three flavors, data are usually analyzed assuming an oscillation between just two of them, *e.g.*, $\nu_\tau \leftrightarrow \nu_e$. The same remark applies to lepton-number violating mixing between two states, *e.g.*, $\nu_e \leftrightarrow \overline{\nu}_\mu$ or $\nu_\mu \leftrightarrow \overline{\nu}_\mu$.

The simplest situation occurs in an "appearance" experiment, where one searches for interactions by neutrinos of a variety not expected in the beam. An example is the search for $\overline{\nu}_e$ interactions in a beam of neutrinos from the π^+ decay chain, which (among other possibilities) might be taken as evidence for $\overline{\nu}_\mu \to \overline{\nu}_e$. For oscillation between two states, the probability that the "wrong" state will appear is given by Eq. 5 in Shrock's "Note on Neutrinos" at the beginning of the Quark and Lepton Full Listings. For our present purposes, this may be rewritten as

$$P = \sin^2 2\theta \, \sin^2(1.27\Delta m^2 L/E) \ , \qquad (1)$$

where L is the distance from the neutrino's production point to its interaction point, and E is its energy. In the above, $|\Delta m^2|$ is in eV^2 and L/E is in km/GeV or m/MeV. Since in a real experiment L and E have some spread, one must average P over the appropriate distributions. As an example, let us make the somewhat unrealistic assumption that $b \equiv 1.27L/E$ has a Gaussian distribution with standard deviation σ_b about a central value b_0. Then:

$$\langle P \rangle = \tfrac{1}{2} \sin^2 2\theta [1 - \cos(2b_0 \Delta m^2) \exp(-2\sigma_b^2 (\Delta m^2)^2)] \qquad (2)$$

The value of $\langle P \rangle$ is set by the experiment. For example, if 230 interactions of the expected flavor are detected and none of the wrong flavor are seen, then $P = 0.010$ at the 90% CL. We can then solve the above expression for $\sin^2 2\theta$ as a function of $|\Delta m^2|$. This function is shown in Fig. 1 for the parameter assumptions given in the caption. Note that:

(a) since the fast oscillations are completely washed out by the resolution for large $|\Delta m^2|$, $\sin^2 2\theta = 2\langle P \rangle$ in this region;

(b) the maximum excursion to the left is to approximately $\langle P \rangle$, and it occurs at $|\Delta m^2| = \pi/2b_0$ eV^2;
(c) for large $\sin^2 2\theta$, $\Delta m^2 \propto (\sin^2 2\theta)^{-1/2}$; and
(d) the intercept at $\sin^2 2\theta = 1$ is at $\sqrt{\langle P \rangle}/b_0$.

The intercept for large $|\Delta m^2|$ is just a measure of running time and backgrounds, while the intercept at $\sin^2 2\theta = 1$ also depends on the mean value of L/E. The wiggles depend on the experimental resolution, but aside from such details the two intercepts completely describe the exclusion region: For large $|\Delta m^2|$, $\sin^2 2\theta$ is constant, and for large $\sin^2 2\theta$ the constant slope is known. For these reasons, it is (nearly) sufficient to summarize the results of an experiment by stating the two intercepts, as is done in the following tables. The reader is referred to the original papers for the two-dimensional plots expressing the actual limits.

If a positive effect is claimed, then the excluded region becomes an included region. This is the case for the HIRATA 92 analysis of R(μ/e) for atmospheric neutrinos.

In a "disappearance" experiment, one looks for the attenuation of the beam neutrinos (for example, ν_k) by mixing with at least one other neutrino eigenstate. (We label such experiments as $\nu_k \not\to \nu_k$.) These experiments fall into two general classes:

(a) Those in which the beam neutrino flux is known, from theory or other measurements. In the high-$|\Delta m^2|$ region, where the oscillation length is small compared to the size of the apparatus, the oscillations are in both directions and the beam intensity is reduced by a factor of two (for two-component mixing). In this case, indicated qualitatively by the "Disappearance A" curve in Fig. 1. sensitivity is maintained for large $|\Delta m^2|$, but with no simple rule relating this asymptote to the maximum excursion to the left. An example is provided by the VUILLEUMIER 82 measurements at the Gösgen reactor.
(b) Those in which the intensity must be measured in the apparatus itself (two detectors, or a "long" detector). Then above some minimum $|\Delta m^2|$ the equilibrium is established upstream, and there is no change in intensity over the length of the apparatus. As a result, sensitivity is lost at high $|\Delta m^2|$, as is qualitatively indicated by the curve "Disappearance B" in Fig. 1. See, for example, DYDAK 84.

Finally, there are more complicated cases, such as in the HIRATA 92B analysis of the Kamiokande II solar neutrino data in terms of the MSW parameters. An irregular region on the $|\Delta m^2|$ vs $\sin^2 2\theta$ is excluded for a combination of physical reasons. It is difficult to represent adequately these graphical data within the strictures of our tables.

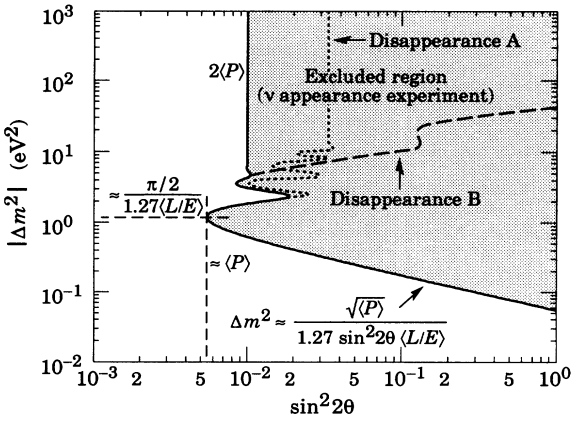

Figure 1: Neutrino oscillation parameter ranges excluded by a toy experiment in which one searches for the appearance of neutrinos not expected in the beam. The probability of appearance, in this case 0.5% at some specified CL, is set by the number of right-flavor events observed and/or information about the flux and cross sections. Here it is assumed that $\langle L/E \rangle = 1$ km GeV^{-1}, and that the distribution of L/E is Gaussian with a 20% standard deviation. The wiggle structure is determined by the resolution function, and the intercepts are determined by the appearance probability and $\langle L/E \rangle$. The leftmost excursion relative to the high-$|\Delta m^2|$ limit and the slope of the lower part of the curve are independent of the experiment. In a disappearance experiment, high-$|\Delta m^2|$ sensitivity is lost unless the incident flux is known. These two possibilities are shown qualitatively by the dashed lines marked "Disappearance A" and "Disappearance B."

Solar ν Experiments

Theoretical calculations of the expected solar rate are shown for comparison with experiment. Note that the expected value in "solar neutrino units" (SNU; 1 SNU = 10^{-36} captures atom^{-1} s^{-1}) depends on the detection reaction.

[48] ANSELMANN 94 result is for a total of 15 initial runs ("GALLEX I") (see footnote for ANSELMANN 93) and 15 new runs ("GALLEX II"). The new runs yield $78 \pm 13 \pm 5$ SNU, confirming to the intitial result.

[49] ABAZOV 91B uses a 30 ton gallium detector to search for the reaction ^{71}Ga$(\nu_e, e)^{71}$Ge. Result is for the first 6 months of operation. The conference report GAVRIN 92 updates this result to $58^{+17}_{-24} \pm 14$ SNU. Since this reaction has a threshold neutrino energy of 0.236 MeV, it is sensitive to the low-energy neutrinos from the main pp chain (whose maximum energy is 0.420 MeV). The upper limit quoted is to be compared with the theoretical expectation of about 130 SNU; see BAHCALL 89B and references therein.

[50] HIRATA 90 data consists of 1040 days with threshold $E_e > 9.3$ MeV (first 450 days) or $E_e > 7.5$ MeV. "The total data sample is also analyzed for short-term variations; within the statistical error, no significant variation is observed." The flux is scaled by the value relative to the standard solar model (SSM) prediction. A theoretical flux of $(5.8 \pm 2.1) \times 10^6$ cm^{-2} s^{-1} is cited, with the central value corresponding to 7.9 SNU for ^{37}Cl experiment (but see TURCK-CHIEZE 93B and other theoretical calculations.) The analysis is more fully reported in HIRATA 91B.

[51] DAVIS 89 is the average from the ^{37}Cl experiment at the Homestake Mine (HOME) from 1970–1988. Earlier averages are given in the references therein.

[52] ANSELMANN 93 result is for 21 runs of combined GALLEX I and GALLEX II data from inverse beta decay reactions in an aqueous solution of Ga^{3}Cl (30.3 tons of natural Ga) in the Gran Sasso underground laboratory. The 15 runs of GALLEX I yield $81 \pm 17 \pm 9$, which replaces the preliminary result of ANSELMANN 92. The first 6 runs with GALLEX II yield $97 \pm 23 \pm 7$ SNU. A typical solar model rate prediction is for 132 SNU, but see the reviews by Bahcall and others.

[53] BAHCALL '93 is a study of 1000 solar models in which each input parameter is chosen from a normal distribution with the appropriate mean and error. It is concluded that "Even if one abuses the solar models by artifically imposing consistency with the Kamiokande experiment, the resulting predictions of all 1000 of the 'fudged' solar models are inconsistent with the result of the chlorine experiment."

[54] HAMPEL 93, by a member of the GALLEX collaboration, is a discussion of possible scenarios to explain the combined solar neutrino experimental data.

[55] TURCK-CHIEZE 93B proposes new results on the solar neutrino predictions and acoustic mode frequencies. See also TURCK-CHIEZE 93 for an extensive review (233 pages, 524 references) concerning the solar interior. Table 17 provides a particularly useful comparison of experiment and theory as of mid-1993.

[56] ANSELMANN 92 reports first observation of solar neutrinos from the pp reaction, using the GALLEX solar neutrino detector in the Gran Sasso Underground Laboratory. The total rate is 2σ below the solar model predictions in the range 124–132 SNU's, but they state that "Our result is consistent with the presence of the full pp neutrino flux expected according the the 'standard solar model' together with a reduced flux of ^{8}B and ^{7}Be neutrinos as observed by the Homestake and Kamiokande experiments."

[57] ANSELMANN 92B discusses implications of the GALLEX observations reported in ANSELMANN 92. They state that "To fit this result together with those of the chlorine and Kamiokande experiments requires severe stretching of the solar models but does not rule out such a procedure, leaving the possibility of massless neutrinos... The Mikheyev-Smirnov-Wolfenstein mechanism provides a good fit, and the GALLEX result fixes the $\Delta(m^2)$ and $\sin^2 2\theta$ parameters in two very confined ranges (around $\Delta(m^2) = 6 \times 10^{-6}$ eV^2 and $\sin^2 2\theta = 7 \times 10^{-3}$ or $\Delta(m^2) = 8 \times 10^{-6}$ eV^2 and $\sin^2 2\theta = 0.6$). Explanations of the solar neutrino problem based on the decay or magnetic interactions of neutrinos are disfavored."

[58] BAHCALL 92 is an extensive up-to-date discussion of the solar neutrino flux calculations with predicted event rates for various different solar neutrino detectors. First published calculation that includes diffusion. "The quoted errors represent the total theoretical range and include the effects on the model predictions of 3σ errors in measured input parameters."

[59] GARCIA 91 reports a new study of ^{37}Ca β decays, with the result that the BAHCALL 88 SSM prediction for ^{37}Cl should be increased from 7.9 to 8.1 SNU.

[60] HIRATA 91 reports a search for day-night and semi-annual variations in the solar neutrino flux observed in the Kamiokande II Detector. The sample is the same 1040 day counting period used for HIRATA 90 and HIRATA 90B. "Within statistical error, no such short-time variations were observed." This result was used to constrain neutrino oscillation parameters, in the framework of oscillations between two mass eigenstates. "A region defined by $\sin^2 2\theta > 0.02$ and 2×10^{-6} eV^2 $< \Delta(m^2) < 1 \times 10^{-5}$ eV^2 is excluded at the 90% CL without any assumptions on the absolute value of the expected solar neutrino flux."

[61] FILIPPONE 90 is a statistical analysis of solar neutrino data to test hypotheses of time dependence. The authors state "we have shown that in our unbiased analysis, the hypothesis of a time-independent ^{37}Cl neutrino capture rate is marginally rejected, having only 2% probability. However, it is disturbing that we are not able to find a simple hypothesis of time variation that would describe the data well. A capture rate anticorrelated with sunspot number, although more probable than the constant rate hypothesis, has a probability of only 6%. One possible explanation of these results is simply the poor statistics of the ^{37}Cl experiment."

[62] HIRATA 90B gives an analysis of the implications of these data for allowed values of $\Delta(m^2)$ and $\sin^2 2\theta$ describing neutrino mixing between two mass eigenstates, in the model of resonant (MSW) neutrino oscillations. The possibility of regeneration as the neutrinos pass through the earth is neglected. Two limits are given, the first from the measured event rate alone, and the second from the combination of the measured event rate and the recoil electron energy spectrum. The latter "disfavor the region of adiabatic solutions $\Delta(m^2) \sim 1.3 \times 10^{-4}$ eV^2 and $7.2 \times 10^{-4} < \sin^2 2\theta < 6.3 \times 10^{-3}$ at 90%CL." The allowed regions in $\sin^2 2\theta$ vs. $\Delta(m^2)$ are given graphically; see Figs. 2(a) and 2(b) in the paper.

[63] BAHCALL 88 "total theoretical range is calculated by evaluating the 3σ uncertainties for all measured input parameters and using the full spread in calculated values for input quantitites that cannot be measured; the uncertainties from different quantities are combined quadratically." (Quotation from BAHCALL 89, p. 301.)

[64] BAHCALL 82 quotes "effective 3σ errors." First extensive discussion of formal uncertainties in the problem.

Deep Underground Detector Experiments

R(μ/e) = (Measured Ratio μ/e) / (Expected Ratio μ/e)

	[67] BERGER	90B	FREJ	Calorimeter

[65] BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atomospheric neutrinos) as 0.36 ± 0.02 ± 0.02, as compared with expected fraction 0.51 ± 0.01 ± 0.05. After cutting the energy range to the KAM2 limits, BEIER 92 finds $R(\mu/e)$ very close to the KAM2 value.

[66] HIRATA 92 uses this ratio because both experimental and theoretical uncertainties in ν_μ and ν_e flux cancel. Part of data set is same as in HIRATA 88 (below), where the equivalent ratio was $0.56^{+0.09}_{-0.08}$.

[67] BERGER 90B reports e/μ = 0.53–0.57 ± 0.09 (data) and 0.56–0.61 ± 0.08 (Monte Carlo), where the range is from different analysis methods. There is thus no significant departure from expectation. See also BEIER 92.

R(ν_μ) = (Measured Flux of ν_μ) / (Expected Flux of ν_μ)

VALUE	DOCUMENT ID		TECN	COMMENT

[82] KETOV 92 is a limit from search for $\bar{\nu}_e$ oscillations using the reaction $\bar{\nu}_e p \to e^+ n$ with the $\bar{\nu}_e$ flux from the Rovno power reactor. They obtain the ratio $R = 0.976 \pm 0.02 \pm 0.015$ for the corrected flux ratios at 12 m and 18 m from the reactor core, and thus report no evidence for neutrino oscillations over distances of order 10 m. Virtually no experimental details are given.

[83] Several different methods of data analysis are used in AFONIN 88. We quote the most stringent limits.

[84] AFONIN 86 and AFONIN 87 also give limits on sin²(2θ) for intermediate values of $\Delta(m^2)$.

[85] VIDYAKIN 87 bound is for L = 32.8 and 92.3 m distance from two reactors.

[86] This bound is from data for L=37.9 m, 45.9 m, and 64.7 m distance from Gösgen reactor.

[87] See the comment for ZACEK 85 in the section on sin²(2θ) below.

[88] This bound comes from a combination of the VUILLEUMIER 82 data at distance 37.9 m from Gösgen reactor and new data at 45.9 m.

[89] VIDYAKIN 87 bound is for L = 32.8 and 92.3 m distance from two reactors.

[90] Several different methods of data analysis are used in AFONIN 88. We quote the most stringent limits. Different upper limits on sin²2θ apply at intermediate values of $\Delta(m^2)$.

[91] This bound is from data for L=37.9 m, 45.9 m, and 64.7 m distance from Gosgen reactor.

[92] ZACEK 85 (Gosgen reactor) gives two sets of bounds depending on what assumptions are used in the data analysis. The bounds in figure 3(a) of ZACEK 85 are progressively poorer for large $\Delta(m^2)$ whereas those of figure 3(b) approach a constant. We list the latter. Both sets of bounds use combination of data from 37.9, 45.9, and 64.7m distance from reactor. ZACEK 85 states "Our experiment excludes this area (the oscillation parameter region allowed by the Bugey data, CAVAIGNAC 84) almost completely, thus disproving the indications of neutrino oscillations of CAVAIGNAC 84 with a high degree of confidence."

[93] This bound comes from a combination of the VUILLEUMIER 82 data at distance 37.9m from Gosgen reactor and new data at 45.9m.

[94] This bound holds for $\Delta(m^2)$ >4 eV^2.

$\Delta(m^2)$ for Given $\sin^2(2\theta)$

VALUE (eV^2)	DOCUMENT ID		COMMENT
0.2 ±0.1	[95] CAVAIGNAC	84	$\overline{\nu}_e p \rightarrow e^+ n$

[95] $\sin^2(2\theta) = 0.25 \pm 0.1$. These are from best fit to data; see CAVAIGNAC 84 for plot of allowed regions in these variables. These data from Bugey reactor.

[97] ASTIER 90 again finds an excess of electrons, as was reported in earlier papers by this collaboration. However, the authors concede that systematic effects weaken the statistical arguments and the consequent claim (in the earlier papers) of neutrino oscillations. An interpretation of these results in terms of neutrino oscillations seems to be already excluded by the BNL E734 (AHRENS 85) and the Los Alamos E645 (DURKIN 88) experiments.

[98] ASTIER 89 reports a a positive effect with ν_e(observed)/ν_e(expected) = 2.2 ± 0.6 and $\overline{\nu}_e$(observed)/$\overline{\nu}_e$(expected) = 1.6 ± 0.9.

[99] LOVERRE 88 reports a less stringent, indirect limit based on theoretical analysis of neutral to charged current ratios.

[126] This bound applies for $\Delta(m^2)$ between 190 and 320 or = 530 eV^2. Less stringent bounds apply for other $\Delta(m^2)$; these are nontrivial for $7 < \Delta(m^2) < 1200$ eV^2.

(C) Searches for Neutrinoless Double β Decay

Limits on an effective Majorana neutrino mass and a lepton-number violating current admixture can be obtained from lifetime limits on $0\nu\beta\beta$ nuclear decay. The derived quantities are highly model-dependent, so the half-life measurements are given first. Where possible we list the references for the matrix elements used in the subsequent analysis. Since rates for the more conventional $2\nu\beta\beta$ decay serve to calibrate the theory, results for this process are also given.

To define the limits on lepton-number violating right-handed current admixtures, we display the relevant part of a phenomenological current-current weak interaction Hamiltonian:

$$H_W = (G_F/\sqrt{2}) \times (J_L \cdot j_L^\dagger + \eta_{RL} J_R \cdot j_L^\dagger + \eta_{LR} J_L \cdot j_R^\dagger + \eta_{RR} J_R \cdot j_R^\dagger) + \text{h.c.}$$

where $j_L^\mu = \bar{e}_L \gamma^\mu \nu_{eL}$, $j_R^\mu = \bar{e}_R \gamma^\mu \nu_{eR}$, and J_L^μ and J_R^μ are left-handed and right-handed hadronic weak currents. Experiments are not sensitive to $\eta_{RL} (\equiv \kappa)$ but quote limits on η_{LR} and η_{RR}. Many authors use an alternative notation in which $\eta_{LR} \equiv \eta$ and $\eta_{RR} \equiv \lambda$. The limits on $\eta_{LR} = \eta$ are of order 10^{-8} while the limits on $\eta_{RR} = \lambda$ are of order 10^{-6}. The reader is warned that a number of earlier experiments did not distinguish between η_{LR} and η_{RR}. Because of evolving reporting conventions and matrix element calculations, we have not tabulated the admixture parameters for experiments published earlier than 1989.

See the section on Marjoran searches for additional limits set by these experiments.

Half-life Measurements and Limits for Double β Decay

In all cases of double beta decay, (Z,A) → (Z+2,A) + $2\beta^-$ + (0 or 2)$\bar{\nu}_e$.

[127] Limit in the case of a transition induced by a Majorana mass.

[128] VUILLEUMIER 93 data is from the search for neutrinoless double beta decay of ^{136}Xe in the TPC experiment in the St. Gotthard tunnel deep underground laboratory.

[129] Limit for lepton-number violating right-handed current-induced (RHC) decay.

[130] BALYSH 92 presents results from the Heidelberg-Moscow experiment searching for neutrinoless double beta decay of ^{76}Ge.

[131] BERNATOWICZ 92 finds ^{128}Te/^{130}Te activity ratio from slope of ^{128}Xe/^{132}Xe vs ^{130}Xe/^{132}Xe ratios during extraction, and normalizes to lead-dated ages for the ^{130}Te lifetime. The authors state that their results imply that "(a) the double beta decay of ^{128}Te has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences... (b) Theoretical calculations ... underestimate the [long half-lives of ^{128}Te ^{130}Te] by 1 or 2 orders of magnitude, pointing to a real supression in the 2ν decay rate of these isotopes. (c) Despite [this], most $\beta\beta$-models predict a *ratio* of 2ν decay widths ... in fair agreement with observation." Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray ^{128}Xe production corrections.

[132] BLUM 92 reports lifetime limits for the decay of ^{100}Mo to several excited states of ^{100}Ru. Limits for decay to the 0_1^+ state are about 30% higher if decay to the 2^+ states are assumed negligable. Uses 99.5% enriched ^{100}Mo.

[133] KUDOMI 92 reports lifetime limits for 0ν and 2ν decays to four excited states of the daughter ^{100}Ru. The limits were obtained from searches for the two individual electrons in coincidence with photons from the decays of the excited states. The experiment was performed in the Kamioka underground laboratory. See EJIRI 91 for the group's ground-state transition measurement.

[134] REUSSER 92 contains the final results for the search for neutrinoless double beta decay of ^{76}Ge in the Gotthard tunnel underground laboratory.

[135] AVIGNONE 91 reports confirmation of the MILEY 90 and VASENKO 90 observations of $2\nu\beta\beta$ decay of ^{76}Ge. Error is 2σ.

[136] BELLOTTI 91 uses difference between natural and enriched ^{136}Xe runs to obtain $\beta\beta0\nu$ limits, leading to "less stringent, but safer limits."

[137] HYKAWY 91 gives new mass spectrometer determination of the ^{76}Ge–^{76}Se mass difference, which for given input for the nuclear matrix elements gives information on limits on Majorana masses. Application to recent ^{76}Ge decay experiments produces no new evidence for $\beta\beta(0\nu)$ decay.

[138] TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the ^{238}U transition in the same range as deduced for ^{130}Te and ^{76}Ge. On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.

[139] WONG 91 replaced by VUILLEUMIER 93.

[140] MILEY 90 claims only "suggestive evidence" for the decay. Error is 2σ.

[141] VASENKO 90 limit based on background statistics. Maximum likelihood solution is >2000.

[142] MORALES 88 notes a 2.5 sigma coincidence rate between electrons with energy 1483.7 ± 0.5 keV in the Ge detector and photons with energy 558 ± 15 keV in the NaI detector, close to the region where neutrinoless $0^+ \rightarrow 2^+$ ^{76}Ge decay should be expected. However, a further sutdy reported in in MORALES 91 rejects this peak at the 95% CL.

[143] BELLOTTI 87 searches for γ rays for 2^+ state decays in corresponding Xe isotopes. Limit for ^{130}Te case argues for dominant $0^+ \rightarrow 0^+$ transition in known decay of this isotope.

[144] ELLIOTT 86 limit agrees with the geochemical limit and strongly disagrees with nuclear theory calculations, casting doubt on their application to derive limits on Majorana neutrino masses and η parameters from limits on neutrinoless double β decay.

[145] HUBERT 85 gives lifetime limits on neutrinoless double β decay of ^{76}Ge to excited states of ^{76}Se.

[146] KIRSTEN 83 reports "2σ" error. References are given to earlier determinations of the ^{130}Te lifetime.

$\langle m_\nu \rangle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double β Decay

$\langle m_\nu \rangle = |\Sigma\ U_{1j}^2 m_{\nu_j}|$, where the sum goes from 1 to n and where n = number of neutrino generations, and ν_j is a Majorana neutrino. Note that U_{1j}^2, not $|U_{1j}|^2$, occurs in the sum. The possibility of cancellations has been stressed.

[147] ALSTON-GARNJOST 93 use the "conservative matrix elements of Engel *et al.* (ENGEL 88).

[148] VUILLEUMIER 93 mass range from parameter range in the Caltech calculations (ENGEL 88). On the basis of these calculations, the BALYSH 92 mass range would be < 2.2–4.4 eV.

[149] BALYSH 92 uses the MUTO 89 matrix elements.

[150] BERNATOWICZ 92 finds these majoron mass limits assuming that the measured geochemical decay width is a limit on the 0ν decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.

[151] ELLIOTT 92 uses the matrix elements of HAXTON 84.

[152] REUSSER 92 contains the final results for the search for neutrinoless double beta decay of ^{76}Ge in the Gotthard tunnel underground laboratory. Range comes from range of nuclear matrix elements used to relate neutrino mass to lifetime limit (ENGEL 88, HAXTON 84, and MUTO 89).

[153] BELLOTTI 91 range of limits comes from range of theoretical calculations considered. Analysis uses difference between natural and enriched ^{136}Xe runs to obtain the $\beta\beta0\nu$ limits, leading to "less stringent, but safer limits."

[154] WONG 91 uses the quasiparticle random phase approximation of ENGEL 88 to extract the above limit for the case of a transition caused by a Majorana neutrino mass.

[155] VASENKO 90 range comes from range of nuclear matrix elements of HAXTON 84, ENGEL 88. On the basis of the MUTO 89 matrix element, the limit will be < 1.3 eV.

[156] BELLOTTI 89 gives model-dependent upper bounds on Majorana neutrino masses and on the admixture of right-handed lepton-number-violating currents.

[157] DANEVICH 89 uses calculations of GROTZ 86.

[158] FISHER 89 model-dependent bounds are for Majorana neutrino masses.

[159] CALDWELL 87 least stringent limit (using HAXTON 84) is listed. Limits given using other nuclear matrix element calculations are 1.5 eV and 0.7 eV.

[160] CALDWELL 86 gives several limits depending on which calculation of nuclear matrix elements is used; we quote the most conservative, i.e., least stringent. Other limits are 1.0 eV and 1.9 eV. Authors note that the overall uncertainty due to the serious disagreement between nuclear calculations and both lab and geochemical measurements for regular 2-neutrino double β decay is also present in these limits.

[161] CALDWELL 85 uses results of HAXTON 81, HAXTON 82. Authors state that limit could be "two or three times larger."

[162] HUBERT 85 limit is obtained from analysis of data using theoretical calculations by HAXTON 81, HAXTON 82.

[163] See Table 1 of BELLOTTI 84 for their assessment of previous bounds.

[164] BELLOTTI 83 limits are obtained from analysis of data using theoretical calculations by DOI 83 and ROSEN 81.

Limits on Lepton-Number Violating ($V+A$) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later.

η_{RR} (10^{-6})	CL%	η_{LR} (10^{-8})	CL%	ISOTOPE	METHOD	DOCUMENT ID

[165] BALYSH 92 uses the MUTO 89 matrix elements.

[166] BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η. Further details of the experiment are given in BERNATOWICZ 93.

[167] REUSSER 92 uses the MUTO 89 matrix elements for this reduction.

Neutrino Bounds from Astrophysics and Cosmology

OMITTED FROM SUMMARY TABLE

The limits on the number of light neutrino types now appears in a separate section (following the τ-lepton section).

See the note on neutrinos by R.E. Shrock in the ν_e section near the beginning of these Listings. For additional information see the ν_e, ν_μ, ν_τ, and heavy-ν sections above.

NOTE ON CONSTRAINTS ON PARTICLES FROM SN 1987A

(by J. Ellis, CERN and D.N. Schramm, Univ. of Chicago)

Since there have been few new developments in 1992–94, the text of this note is omitted. The reader is referred to the 1992 edition (Phys. Rev. **D45**, VI. 42 (Part II, June 1992)).

ν MASS

The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to $m_{\rm tot}$ given by

$$m_{\rm tot} = \sum_\nu (g_\nu/2) m_\nu \ ,$$

where g_ν is the number of spin degrees of freedom for ν plus $\overline{\nu}$: $g_\nu = 4$ for neutrinos with Dirac masses; $g_\nu = 2$ for Majorana neutrinos. The limits on high mass ($m_\nu > 1$ MeV) neutrinos apply separately to each neutrino type.

Limit on Total ν MASS, m_{tot}

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to m_{tot}. For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85.

Astrophysical and Cosmological Limits on ν MASSES

If neutrinos are present as dark matter in galactic halos, limits on neutrino masses have been computed based on neutrino degeneracy and Fermi statistics. The results depend strongly on assumptions. See the references.

QUARKS

NOTE ON QUARK MASSES

A. Introduction

This note discusses some of the theoretical issues involved in the determination of quark masses. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses cannot be measured directly, but must be determined indirectly through their influence on hadron properties. As a result, the values of the quark masses depend on precisely how they are defined; there is no one definition that is the obvious choice. Though one often speaks loosely of quark masses as one would of the electron or muon mass, any careful statement of a quark mass value must make reference to a particular computational scheme that is used to extract the mass from observations. It is important to keep this scheme dependence in mind when using the quark mass values tabulated in the data listings.

The simplest way to define the mass of a quark is by making a fit of the hadron mass spectrum to a nonrelativistic quark model. The quark masses are defined as the values obtained from the fit. The resulting masses only make sense in the limited context of a particular quark model. They depend on the phenomenological potential used, and on how relativistic effects are modelled. The quark masses used in potential models also cannot be connected with the quark mass parameters in the QCD Lagrangian. Fortunately, there exist other definitions of the quark mass that have a more general significance, though they also depend on the method of calculation. The purpose of this review is to explain the most important such definitions and their interrelations.

B. Mass parameters and the QCD Lagrangian

The QCD Lagrangian for N_F quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \bar{q}_k \left(i\not{D} - m_k\right) q_k - \tfrac{1}{4} G_{\mu\nu} G^{\mu\nu} \,, \qquad (1)$$

where $\not{D} = (\partial_\mu - igA_\mu)\,\gamma^\mu$ is the gauge covariant derivative, A_μ is the gluon field, $G_{\mu\nu}$ is the gluon field strength, m_k is the mass parameter of the k^{th} quark, and q_k is the quark Dirac field. The QCD Lagrangian Eq. (1) gives finite scattering amplitudes after renormalization, a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter μ. The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter μ. The most commonly used renormalization scheme for QCD perturbation theory is the $\overline{\text{MS}}$ scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of

dynamical chiral symmetry breaking, $\Lambda\chi$, is around 1 GeV. It is conventional to call quarks heavy if $m > \Lambda\chi$, so that explicit chiral symmetry breaking dominates, and light if $m < \Lambda\chi$, so that spontaneous chiral symmetry breaking dominates. The c, b, and t quarks are heavy, and the u, d and s quarks are light. The computations for light quarks involve an expansion in $m_q/\Lambda\chi$ about the limit $m_q = 0$, whereas for heavy quarks, they involve an expansion in $\Lambda\chi/m_q$ about $m_q = \infty$. The corrections are largest for the s and c quarks, which are the heaviest light quark and the lightest heavy quark, respectively.

At high energies or short distances, nonperturbative effects such as chiral symmetry breaking are unimportant, and one can in principle analyze mass-dependent effects using QCD perturbation theory to extract the quark mass values. The QCD computations are conventionally performed using the $\overline{\rm MS}$ scheme at a scale $\mu \gg \Lambda\chi$, and give the $\overline{\rm MS}$ "running" mass $\overline{m}(\mu)$. The μ dependence of $\overline{m}(\mu)$ at short distances can be calculated using the renormalization group equations.

For heavy quarks, one can obtain useful information on the quark masses by studying the spectrum and decays of hadrons containing heavy quarks. One method of calculation uses the heavy quark effective theory (HQET), which defines a HQET quark mass m_Q. Other commonly used definitions of heavy quark masses such as the pole mass are discussed in Sec. C. QCD perturbation theory at the heavy quark scale $\mu = m_Q$ can be used to relate the various heavy quark masses to the $\overline{\rm MS}$ mass $\overline{m}(\mu)$, and to each other.

For light quarks, one can obtain useful information on the quark mass ratios by studying the properties of the light pseudoscalar mesons using chiral perturbation theory, which utilizes the symmetries of the QCD Lagrangian Eq. (1). The quark mass ratios determined using chiral perturbation theory are those in a subtraction scheme that is independent of the quark masses themselves, such as the $\overline{\rm MS}$ scheme.

A more detailed discussion of the masses for heavy and light quarks is given in the next two sections. The $\overline{\rm MS}$ scheme applies to both heavy and light quarks. It is also commonly used for predictions of quark masses in unified theories, and for computing radiative corrections in the Standard Model. For this reason, we use the $\overline{\rm MS}$ scheme as the standard scheme in reporting quark masses. One can easily convert the $\overline{\rm MS}$ masses into other schemes using the formulæ given in this review.

C. Heavy quarks

The commonly used definitions of the quark mass for heavy quarks are the pole mass, the $\overline{\rm MS}$ mass, the Georgi-Politzer mass, the potential model mass used in ψ and Υ spectroscopy, and the HQET mass.

The strong interaction coupling constant at the heavy quark scale is small, and one can compute the heavy quark propagator using QCD perturbation theory. For an observable particle such as the electron, the position of the pole in the propagator is the definition of the particle mass. In QCD this definition of the quark mass is known as the pole mass m_P, and is independent of the renormalization scheme used. It is known that the on-shell quark propagator has no infrared divergences up to (at least) two-loop order [1], so this provides a definition of the quark mass up to order $\alpha_s(m_P)^2$. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory.

The $\overline{\rm MS}$ running mass $\overline{m}(\mu)$ is defined by regulating the QCD theory using dimensional regularization, and subtracting the divergences using the modified minimal subtraction scheme. The $\overline{\rm MS}$ scheme is particularly convenient for Feynman diagram computations, and is the most commonly used subtraction scheme.

The Georgi-Politzer mass $\widehat{m}(\xi)$ is defined using the momentum space subtraction scheme at the spacelike point $-p^2 = M^2$ [2], with $M^2 = (\xi + 1)m_P^2$. It is often used in computations involving QCD sum rules [3], which can be used to extract heavy quark masses. QCD sum rules are discussed in more detail in the next section on light quark masses.

Lattice gauge theory calculations can be used to obtain heavy quark masses from ψ and Υ spectroscopy. The quark masses are obtained by comparing a nonperturbative computation of the meson spectrum with the experimental data. The lattice quark mass values can then be converted into quark mass values in the continuum QCD Lagrangian Eq. (1) using lattice perturbation theory at a scale given by the inverse lattice spacing. A recent computation gives a b-quark pole mass of 4.94 ± 0.15 GeV [4].

Potential model calculations of the hadron spectrum also involve the heavy quark mass. There is no way to relate the quark mass as defined in a potential model to the quark mass parameter of the QCD Lagrangian, or to the pole mass. Even in the heavy quark limit, the two masses can differ by nonperturbative effects of order $\Lambda_{\rm QCD}$. There is also no reason why the potential model quark mass should be independent of the particular form of the potential used.

Recent work on the heavy quark effective theory [5–9] has provided a definition of the quark mass for a heavy quark that is valid when one includes nonperturbative effects and will be called the HQET mass m_Q. The HQET mass is particularly useful in the analysis of the $1/m_Q$ corrections in HQET. The HQET mass is not the same as the pole mass, a distinction that is often overlooked in the literature. Physical quantities such as hadron masses can in principle be computed in the heavy quark effective theory in terms of the HQET mass m_Q. The computations cannot be done analytically in practice because of nonperturbative effects in QCD, which also prevent a direct extraction of the quark masses from the original QCD Lagrangian, Eq. (1). Nevertheless, for heavy quarks, it is possible to parametrize the nonperturbative effects to a given order in the $1/m_Q$ expansion in terms of a few unknown constants that can be obtained from experiment. For example,

the B and D meson masses in the heavy quark effective theory are given in terms of a single nonperturbative parameter $\overline{\Lambda}$,

$$M(B) = m_b + \overline{\Lambda} + \mathcal{O}\left(\frac{\overline{\Lambda}^2}{m_b}\right) ,$$

$$M(D) = m_c + \overline{\Lambda} + \mathcal{O}\left(\frac{\overline{\Lambda}^2}{m_c}\right) ,$$

This allows one to determine the mass difference $m_b - m_c = M(B) - M(D) = 3.4$ GeV up to corrections of order $\overline{\Lambda}^2/m_b - \overline{\Lambda}^2/m_c$. The extraction of the individual quark masses m_b and m_c requires some knowledge of $\overline{\Lambda}$. An estimate of $\overline{\Lambda}$ using QCD sum rules gives $\overline{\Lambda} = 0.57 \pm 0.07$ GeV [10]. The HQET masses with this value of $\overline{\Lambda}$ are $m_b = 4.74 \pm 0.14$ GeV and $m_c = 1.4 \pm 0.2$ GeV, where the spin averaged meson masses $(3M(B^*) + M(B))/4$ and $(3M(D^*) + M(D))/4$ have been used to eliminate the spin-dependent $\mathcal{O}(\overline{\Lambda}^2/m_Q)$ correction terms. The errors reflect the uncertainty in $\overline{\Lambda}$ and the unknown spin-averaged $\mathcal{O}(\overline{\Lambda}^2/m_Q)$ correction. The errors do not include any theoretical uncertainty in the QCD sum rules, which could be large. A quark model estimate suggests that $\overline{\Lambda}$ is the constituent quark mass (≈ 350 MeV), which differs significantly from the sum rule estimate. In HQET, the $1/m_Q$ corrections to heavy meson decay form-factors are also given in terms of $\overline{\Lambda}$. Thus an accurate enough measurement of these form-factors could be used to extract $\overline{\Lambda}$ directly from experiment, which then determines the quark masses up to corrections of order $1/m_Q$.

The quark mass m_Q of HQET can be related to other quark mass parameters using QCD perturbation theory at the scale m_Q. The relation between these masses in QCD perturbation theory at one loop is [11]

$$\begin{aligned} m_Q &= \overline{m}(\mu)\left[1 + \frac{\overline{\alpha}_s(\mu)}{3\pi}\left(3\log\mu^2/m^2 + 4\right)\right] , \\ m_Q &= \widehat{m}(\xi)\left[1 + \frac{\widehat{\alpha}_s(\xi)}{\pi}\frac{\xi+2}{\xi+1}\log\left(\xi+2\right)\right] , \\ m_Q &= m_P , \end{aligned} \tag{2}$$

where $\overline{\alpha}_s(\mu)$ and $\widehat{\alpha}_s(\xi)$ are the strong interaction coupling constants in the $\overline{\rm MS}$ and momentum space subtraction schemes, respectively.

D. Light quarks

For light quarks, one can use the techniques of chiral perturbation theory to extract quark mass ratios. The light quark part of the QCD Lagrangian Eq. (1) has a chiral symmetry in the limit that the light quark masses are set to zero, under which left- and right-handed quarks transform independently. The mass term explicitly breaks the chiral symmetry, since it couples the left- and right-handed quarks to each other. A systematic analysis of this explicit chiral symmetry breaking provides some information on the light quark masses.

It is convenient to think of the three light quarks u, d and s as a three component column vector Ψ, and to write the mass term for the light quarks as

$$\overline{\Psi} M \Psi = \overline{\Psi}_L M \Psi_R + \overline{\Psi}_R M \Psi_L , \tag{3}$$

where M is the quark mass matrix M,

$$M = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix} . \tag{4}$$

The mass term $\overline{\Psi} M \Psi$ is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the limit that $M \to 0$, there is an independent SU(3) flavor symmetry for the left- and right-handed quarks. This $G_\chi = \mathrm{SU}(3)_L \times \mathrm{SU}(3)_R$ chiral symmetry of the QCD Lagrangian is spontaneously broken, which leads to eight massless Goldstone bosons, the π's, K's, and η, in the limit $M \to 0$. The symmetry G_χ is only an approximate symmetry, since it is explicitly broken by the quark mass matrix M. The Goldstone bosons acquire masses which can be computed in a systematic expansion in M in terms of certain unknown nonperturbative parameters of the theory. For example, to first order in M one finds that [12,13]

$$\begin{aligned} m_{\pi^0}^2 &= B\left(m_u + m_d\right) , \\ m_{\pi^\pm}^2 &= B\left(m_u + m_d\right) + \Delta_{em} , \\ m_{K^0}^2 = m_{\overline{K}^0}^2 &= B\left(m_d + m_s\right) , \\ m_{K^\pm}^2 &= B\left(m_u + m_s\right) + \Delta_{em} , \\ m_\eta^2 &= \frac{1}{3} B\left(m_u + m_d + 4m_s\right) , \end{aligned} \tag{5}$$

with two unknown parameters B and Δ_{em}, the electromagnetic mass difference. From Eq. (5), one can determine the quark mass ratios [12]

$$\begin{aligned} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^+}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56 , \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.1 , \end{aligned} \tag{6}$$

to lowest order in chiral perturbation theory. The error on these numbers is the size of the second-order corrections, which are discussed at the end of this section. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of M, and any multiple of M has the same G_χ transformation law as M. This can be seen from Eq. (5), where all quark masses occur only in the form Bm, so that B and m cannot be determined separately.

The mass parameters in the QCD Lagrangian have a scale dependence due to radiative corrections, and are renormalization scheme dependent. Since the mass ratios extracted using

chiral perturbation theory use the symmetry transformation property of M under the chiral symmetry G_χ, it is important to use a renormalization scheme for QCD that does not change this transformation law. Any quark mass independent subtraction scheme such as $\overline{\rm MS}$ is suitable. The ratios of quark masses are scale independent in such a scheme.

The absolute normalization of the quark masses can be determined by using methods that go beyond chiral perturbation theory, such as QCD sum rules [3]. Typically, one writes a sum rule for a quantity such as B in terms of a spectral integral over all states with certain quantum numbers. This spectral integral is then evaluated by assuming it is dominated by one (or two) of the lowest resonances, and using the experimentally measured resonance parameters [14]. There are many subtleties involved, which cannot be discussed here [14].

Another method for determining the absolute normalization of the quark masses, is to assume that the strange quark mass is equal to the SU(3) mass splitting in the baryon multiplets [12,14]. There is an uncertainty in this method since in the baryon octet one can use either the Σ–N or the Λ–N mass difference, which differ by about 75 MeV, to estimate the strange quark mass. It is also not possible to relate this definition of mass to the mass parameters in the QCD Lagrangian, which are scale and scheme dependent. It is often simply assumed that the baryon mass splittings give the $\overline{\rm MS}$ quark masses renormalized at a scale $\mu = 1$ GeV.

One can extend the chiral perturbation expansion Eq. (5) to second order in the quark masses M to get a more accurate determination of the quark mass ratios. The meson mass terms in the chiral Lagrangian to second order in the quark mass matrix M are [16]

$$\mathcal{L} = \tfrac{1}{4}{\rm Tr}\left(\chi^\dagger U + \chi U^\dagger\right) + L_6\ \left[{\rm Tr}\left(\chi^\dagger U + \chi U^\dagger\right)\right]^2 + L_7\ \left[{\rm Tr}\left(\chi^\dagger U - \chi U^\dagger\right)\right]^2 + L_8\ {\rm Tr}\left(\chi^\dagger U \chi^\dagger U + \chi U^\dagger \chi U^\dagger\right) \quad (7)$$

where $\chi = 2BM$ and U is the exponential of the pion field. Eq. (7) defines the chiral Lagrangian parameters L_{6-8}. The meson masses are obtained by expanding Eq. (7) in a power series in the meson fields.

There is a subtlety that arises at this order [15], because

$$M\left(M^\dagger M\right)^{-1} \det M^\dagger \quad (8)$$

transforms in the same way under G_χ as M, so that one can make the replacement $M \to M(\lambda) = M + \lambda M\left(M^\dagger M\right)^{-1} \det M^\dagger$,

$$M(\lambda) = {\rm diag}\left(m_u(\lambda),\ m_d(\lambda),\ m_s(\lambda)\right)$$
$$= {\rm diag}\left(m_u + \lambda m_d m_s,\ m_d + \lambda m_u m_s,\ m_s + \lambda m_u m_d\right) \quad (9)$$

One can only determine the ratios $m_i(\lambda)/m_j(\lambda)$ using second-order chiral perturbation theory, not the ratios $m_i/m_j = m_i(\lambda = 0)/m_j(\lambda = 0)$, since second-order terms in the chiral Lagrangian are indistinguishable from first-order terms with a redefined quark mass. M and $M(\lambda)$ have the same chiral transformation properties, which implies that the meson masses depend on L_{6-8} only in the linear combinations $L_6 - L_7$ and $L_6 + 2L_8$. One linear combination is left undetermined, so one cannot determine the quark mass ratios to second order in chiral perturbation theory without an independent determination of one of the L_i's.

Dimensional analysis can be used to estimate [17] that second-order corrections in chiral perturbation theory due to the strange quark mass are of order $\lambda m_s \sim 0.25$. The ambiguity due to the redefinition Eq. (9) (which corresponds to a second-order correction) can produce a sizeable uncertainty in the ratio m_u/m_d. The lowest-order value $m_u/m_d = 0.56$ gets corrections of order $\lambda m_s(m_d/m_u - m_u/m_d) \sim 30\%$, whereas m_s/m_d gets a smaller correction of order $\lambda m_s(m_u/m_d - m_u m_d/m_s^2) \sim 15\%$. A more quantitative discussion of second-order effects can be found in Refs. 15,16,18. Since the second-order terms have a single parameter ambiguity, the value of m_u/m_d is related to the value of m_s/m_d.

The ratio m_u/m_d is of great interest since there is no strong CP problem if $m_u = 0$. To determine m_u/m_d requires determining the parameters L_{6-8} in the meson Lagrangian Eq. (7), or equivalently, fixing λ in the mass redefinition Eq. (9). There has been considerable effort to determine the chiral Lagrangian parameters accurately enough to determine m_u/m_d, for example from the analysis of the decays $\psi' \to \psi + \pi^0, \eta$, the decay $\eta \to 3\pi$, and by using sum rules [14,19–21]. m_u/m_d can also be extracted from η' decays. This requires the knowledge of chiral lagrangian parameters for the η', such as L_{14} which is defined in [21]. All of these methods have large uncertainties, but indicate that $m_u/m_d \neq 0$. This conclusion has been questioned by Ref. 20 which argues that instanton corrections produce effects like the redefinition Eq. (9), and can explain the experimental observations even if $m_u = 0$.

Eventually, lattice gauge theory methods will be accurate enough to be able to compute meson masses directly from the QCD Lagrangian Eq. (1), and thus determine the light quark masses. For a reliable determination of quark masses, these computations will have to be done with dynamical fermions, and with a small enough lattice spacing that one can accurately compute the relation between lattice and continuum Lagrangians.

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order 350 MeV for the u and d quarks. Constituent quark masses model the effects of dynamical chiral symmetry breaking, and are not related to the quark mass parameters m_k of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

E. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using the wide variety of theoretical methods outlined

above. Each method involves its own set of approximations and errors. In most cases, the errors are a best guess at the size of neglected higher-order corrections. The expansion parameter for the approximations is not much smaller than unity (for example it is $m_K^2/\Lambda_\chi^2 \approx 0.25$ for the chiral expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes. For example, assuming that the HQET mass m_b is 4.7 GeV, and $\overline{\alpha}_s(m_b) \approx 0.2$ gives the $\overline{\rm MS}$ b-quark mass $\overline{m}_b(\mu = m_b) = 4.3$ GeV using the one-loop formula in Eq. (2). The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme. When using the data listings, it is important to remember that the numerical value for a quark mass is meaningless without specifying the particular scheme in which it was obtained.

LIGHT QUARKS — u, d, s

u-QUARK MASS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\rm MS}$ at a scale $\mu \approx 1$ GeV. The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of d and u masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

[8] ADAMI 93 obtain $m_d - m_u$=3 ± 1 MeV at μ=0.5 GeV using isospin-violating effects in QCD sum rules.
[9] NEFKENS 92 results for $m_d - m_u$ are 3.1 ± 0.4 MeV from meson masses and 3.6 ± 0.4 MeV from baryon masses.
[10] BARDUCCI 88 renormalized quark mass at 1 GeV. Uses a calculation of the effective potential for $\overline{\psi}\psi$ in QCD, and estimates for $\Sigma(p^2)$.
[11] DOMINGUEZ 87 uses QCD sum rules to obtain m_u+m_d = 15.5 ± 2.0 MeV and $m_d - m_u$ = 6 ± 1.5 MeV.
[12] KREMER 84 obtain m_u+m_d=21 ± 2 MeV at Q^2 = 1 GeV^2 using SVZ values for quark condensates; they obtain m_u+m_d=35 ± 3 MeV at Q^2 = 1 GeV^2 using factorization values for quark condensates.
[13] GASSER 82 uses chiral perturbation theory for the mass ratios, and uses QCD sum rules to extract the absolute values. The renormalization scale is 1 GeV.
[14] PAGELS 80 uses lowest-order chiral perturbation theory plus an estimate of $\langle\overline{q}q\rangle$.
[15] PAGELS 80 uses lowest-order chiral perturbation theory plus an estimate of $\langle\overline{q}q\,\overline{q}q\rangle$ correlation function.
[16] WEINBERG 77 assumes that the baryon SU(3) splittings are equal to m_s.
[17] GASSER 75 uses inelastic electron scattering and SU(6).

s-QUARK MASS

[18] NEFKENS 92 results for $m_s-(m_u+m_d)/2$ are 111 ± 10 MeV from meson masses and 163 ± 15 MeV from baryon masses.
[19] DOMINGUEZ 91 uses QCD sum rules.
[20] BARDUCCI 88 renormalized quark mass at 1 GeV. Uses a calculation of the effective potential for $\overline{\psi}\psi$ in QCD, and estimates for $\Sigma(p^2)$.
[21] KREMER 84 obtain m_u+m_s=245 ± 10 MeV at $Q^2 = 1$ GeV^2 using SVZ values for quark condensates; they obtain m_u+m_s=270 ± 10 MeV at $Q^2 = 1$ GeV^2 using factorization values for quark condensates.
[22] GASSER 82 uses chiral perturbation theory for the mass ratios, and uses QCD sum rules to extract the absolute values. The renormalization scale is 1 GeV.
[23] PENSO 82 uses SVZ sum rules to put a lower bound on the strange quark mass.
[24] PAGELS 80 uses lowest-order chiral perturbation theory plus an estimate of $\langle\overline{q}q\rangle$.
[25] PAGELS 80 uses lowest-order chiral perturbation theory plus an estimate of $\langle\overline{q}q\,\overline{q}q\rangle$ correlation function.
[26] WEINBERG 77 assumes that the baryon SU(3) splittings are equal to m_s.
[27] GASSER 75 is based on SU(6).

[28] CHOI 92 result obtained from the decays $\psi(2S) \to J/\psi(1S)\pi$ and $\psi(2S) \to J/\psi(1S)\eta$, and a dilute instanton gas estimate of some unknown matrix elements.
[29] DONOGHUE 92 result is from a combined analysis of meson masses, $\eta \to 3\pi$ using second-order chiral perturbation theory including nonanalytic terms, and $(\psi(2S) \to J/\psi(1S)\pi)/(\psi(2S) \to J/\psi(1S)\eta)$.
[30] DONOGHUE 92B computes quark mass ratios using $(\psi(2S) \to J/\psi(1S)\pi)/(\psi(2S) \to J/\psi(1S)\eta)$, and an estimate of L_{14} using Weinberg sum rules.
[31] GERARD 90 uses large N and η-η' mixing.
[32] LEUTWYLER 90B determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine L_7.
[33] MALTMAN 90 uses second-order chiral perturbation theory including nonanalytic terms for the meson masses. Uses a criterion of "maximum reasonableness" that certain coefficients which are expected to be of order one are ≤ 3.
[34] CHOI 89 uses second-order chiral perturbation theory and a dilute instanton gas estimate of second-order coefficients in the chiral lagrangian.
[35] KAPLAN 86 uses second-order chiral perturbation theory including nonanalytic terms for the meson masses. Assumes that less than 30% of the mass squared of the pion is due to second-order corrections.
[36] GASSER 82 uses chiral perturbation theory for the meson and baryon masses.
[37] LANGACKER 79 result is from a fit to the meson and baryon mass spectrum, and the decay $\eta \to 3\pi$. The electromagnetic contribution is taken from Socolow rather than from Dashen's formula.
[38] LANGACKER 79B result uses LANGACKER 79 and also ρ-ω mixing.
[39] WEINBERG 77 uses lowest-order chiral perturbation theory for the meson and baryon masses and Dashen's formula for the electromagnetic mass differences.

c

$I(J^P) = 0(\frac{1}{2}^+)$

Charge = $\frac{2}{3}$ e Charm = +1

c-QUARK MASS

The c-quark mass is estimated from charmonium and D masses. It corresponds to the "running" mass in the $\overline{MS}$ scheme. We have converted masses in other schemes to the $\overline{MS}$ scheme using one-loop QCD pertubation theory with $\alpha_s(\mu=m_c) = 0.39$. The range 1.0–1.6 GeV for the $\overline{MS}$ mass corresponds to 1.2–1.9 GeV for the pole mass (see the "Note on Quark Masses").

> 72	95		[14] ABE	90B	CDF	e + μ
> 77	95		[15] ABE	90C	CDF	e + jets + missing E_T
> 69	95		[16] AKESSON	90	UA2	e + jets + missing E_T
> 60	95		ALBAJAR	90B	UA1	e or μ + jets, μμ + jet
			[17] BARGER	90E	RVUE	$t \to bH^+$
> 41	95		[18] ALBAJAR	88	UA1	e or μ + jets

[8] ABACHI 94 search for eμ + jets, ee + jets, e + jets, and μ + jets. Production cross section with soft-gluon resummation of LAENEN 94 is used. The limit decreases to >122 GeV if $O(\alpha_s^3)$ cross section is employed for comparison with ABE 92.
[9] ABE 94E search for ee, eμ, and μμ dilepton final states and single lepton + b-jet final states. They observe a total of 15 top topology tags (12 events of which three are doubly tagged) with an expected background of $5.96^{+0.49}_{-0.44}$. The mass determination is from 7 single-lepton + b-jet events which have four jets. Their $\ell\ell$ limit uses the production cross section with soft gluon resummation from LAENEN 94.
[10] ABE 92 search for ee, eμ, μμ dilepton final states and (e or μ) plus a b-quark jet. The b jet is tagged by a soft muon. The 90%CL limit is 95 GeV. Superseded by ABE 94E $\ell\ell$ limit.
[11] ALITTI 92F search for $t \to bH^+$, $H^+ \to \tau\nu_\tau$ with τ decaying hadronically. m_t between 50 and 70 GeV is excluded if $m_t - m_{H^+} = m_b + (\lesssim$ a few–10 GeV). See their Figs. 5,6 for the excluded region for $B(H^+ \to \tau\nu_\tau) = 1, 0.5$.
[12] ALBAJAR 91B searched for the decay $t \to H^+ b$ using single muon and dimuon events and assuming $B(H^+ \to \tau^+\nu) \geq 0.95$. The limit holds for $m_{H^+} \lesssim m_t - m_b -$ (3–6) GeV.
[13] BAER 91B argue that a top quark as light as 60 GeV (65 GeV, if the minimal SUSY framework is assumed) may have escaped detection at CDF if a supersymmetric decay mode is open.
[14] ABE 90B exclude the region 28–72 GeV.
[15] ABE 90C cannot exclude $m_t < 40$ GeV, but this region is ruled out by other experiments. They study events with an energetic electron, missing transverse energy and two or more jets. Only the $t\bar{t}$ contribution (not $W \to tb$) is relevant for these masses. See also ABE 91.
[16] AKESSON 90 searched for events having an electron with $p_T > 12$ GeV, missing momentum > 15 GeV, and a jet with $E_T > 10$ GeV, $|\eta| < 2.2$, and excluded m_t between 30 and 69 GeV.
[17] BARGER 90E claim that ABE 90C data exclude most regions of two-Higgs-doublet models with $m_t < 80$ GeV even if $t \to bH^+$ decay is allowed.
[18] ALBAJAR 88 value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88. Superseded by ALBAJAR 90B.

Lepton & Quark Full Listings

t Quark

INDIRECT MASS LIMITS for *t* Quark from Standard Model Electroweak Fit

The RVUE values are based on the data described in the footnotes. Earlier RVUE's are superseded but have been left in the Listings to show the progress.

"OUR EVALUATION" below is for our fit to electroweak data described in the "Standard Model of Electroweak Interactions" section. This fit result does not include direct measurements of m_t. The second error corresponds to m_H=300$^{+700}_{-240}$ GeV.

[19] ABREU 94 value is for $\alpha_s(m_Z)$ constrained to 0.123 $\pm$ 0.005. The second error corresponds to m_H = 300$^{+700}_{-240}$ GeV.

[20] ACCIARRI 94 value is for $\alpha_s(m_Z)$ constrained to 0.124 $\pm$ 0.006. The second error corresponds to m_H = 300$^{+700}_{-240}$ GeV.

[21] AKERS 94 result is from fit with free α_s. The second error corresponds to m_H=300$^{+700}_{-240}$ GeV. The 95%CL limit is m_t <210 GeV.

[22] BUSKULIC 94 result is from fit with free α_s. The second error is from m_H=300$^{+700}_{-240}$ GeV.

[23] ELLIS 94 is fit to electroweak data available in summer 1993. m_t, m_H, and α_s are adjusted to minimize χ^2, yielding m_t above, m_H = 35$^{+205}_{-26}$ GeV, and $\alpha_s(m_Z)$ = 0.116$^{+0.007}_{-0.006}$.

[24] ACTON 93D result is from fit with free α_s. The second error corresponds to m_H=300$^{+700}_{-240}$ GeV. The 95%CL limit is m_t <180 GeV. Negative statistical error is larger than $-$46. Superseded by AKERS 94.

[25] ADRIANI 93M used $\alpha_s(m_Z)$=0.124 $\pm$ 0.006. Second error corresponds to m_H=50 GeV – 1 TeV. Superseded by ACCIARRI 94.

[26] ALTARELLI 93 limit is from fit to electroweak data available in summer '92 but uses only the parameter corresponding to $Zb\bar{b}$ vertex correction. $\alpha_s(m_Z)$ = 0.118 $\pm$ 0.007 is used.

[27] BLONDEL 93 is $m_t - m_H$ fit to LEP data available in spring '93. α_s = 0.117 $\pm$ 0.005 is used and m_t >108 GeV, m_H > 62.5 GeV imposed. 95%CL limit is 185 GeV.

[28] BUSKULIC 93J second error is from m_H=300$^{+700}_{-250}$ GeV. Superseded by BUSKULIC 94.

[29] BUSKULIC 93M limit is from $\Gamma(b\bar{b})/\Gamma(\text{had})$ = 0.2193 $\pm$ 0.0029. The best value is m_t = 50 $\pm$ 70 GeV. The CDF limit m_t >91 GeV is imposed to obtain the limit.

[30] ELLIS 93B fit to electroweak data available in spring '93. m_H is adjusted to minimize χ^2 (even below the present direct limit) and $\alpha_s(m_Z)$ = 0.123 $\pm$ 0.006 is used. 95%CL limit of m_t <155 GeV is claimed.

[31] MONTAGNA 93 perform fit to LEP cross-section and asymmetry data taken in 1989/90. The second error corresponds to m_H =300$^{+700}_{-235}$ GeV. Direct limits on m_t, m_H are imposed. α_s is adjusted to minimize χ^2. Updated in MONTAGNA 93B.

[32] MONTAGNA 93B is an update of MONTAGNA 93, including fits to realistic (i.e. with experimental cuts) cross sections and asymmetries. m_Z and α_s are adjusted to minimize χ^2. m_H is fixed at m_H = 300 GeV.

[33] See Fig. 2 of NOVIKOV 93B for χ^2 contour in $m_t - m_H$ plane calculated from m_W, $\Gamma(\ell\ell)$, and $A_{FB}^{\ell\ell}$ data available in summer '92.

[34] PASSARINO 93 fit is to LEP and m_W data available in spring '93. α_s is adjusted to minimize χ^2. The second error is from m_H=300$^{+700}_{-240}$ GeV.

[35] QUAST 93 is fit to LEP data taken up to 1991. α_s is fitted (0.133 $\pm$ 0.008 $\pm$ 0.002). The second error is from m_H=300$^{+700}_{-240}$ GeV.

[36] ALITTI 92B assume m_H = 100 GeV. The 95%CL limit is m_t < 250 GeV for m_H < 1 TeV.

[37] BANERJEE 92 is a fit to LEP data taken in '90 as well as m_W. The second error is from m_H=300$^{+700}_{-250}$ GeV. $\alpha_s(m_Z)$ = 0.118 $\pm$ 0.008 is used. Fit to LEP data only gives m_t = 99 $\pm$ 48 $\pm$ 22 GeV.

[38] BLONDEL 92 limit is from $\Gamma(b\bar{b})/\Gamma(\text{had})$, $\sin^2\theta_W^{\text{eff}}$ from asymmetries, and $\alpha_s(m_Z)$ = 0.117 $\pm$ 0.004 (data available in spring '92). m_t >91 GeV imposed. The limit is sensitive to the value of α_s.

[39] Limit from Z cross sections, leptonic forward-backward asymmetries, τ polarization asymmetry, quark charge asymmetry, and bb and cc forward-backward asymmetries.

[40] DECAMP 92B uses α_s = 0.121 $\pm$ 0.008. The second error is from m_{H^0} = 200$^{+800}_{-150}$ GeV. The "Electroweak" value combines ALEPH Z data and m_W/m_Z from ALITTI 90B and ABE 90G.

[41] DELAGUILA 92 is fit to electroweak data including LEP data taken '90. The value is for m_H = 100 GeV, $\alpha_s(m_Z)$ = 0.12 fixed. For m_H = 1 TeV, m_t = 140$^{+19}_{-21}$ GeV.

[42] DELAGUILA 92B perform two-dimensional fit to various electroweak data with direct limits on m_t,m_H.

[43] ELLIS 92 is an update of ELLIS 90B to include the latest LEP, UA2, CDF, and CHARM II results presented at the Lepton-Photon and EPS Conference, July 1991. α_s = 0.115 $\pm$ 0.008 assumed and m_H left free. Fit gives 1.3 GeV < m_H < 160 GeV, CL = 68% for m_t = 130 GeV.

[44] ELLIS 92E perform fit to electroweak data available in spring '92. m_H is adjusted to minimize χ^2 and $\alpha_s(m_Z)$ = 0.118 $\pm$ 0.008 is used.

[45] LANGACKER 92B consider the effect of an extra Z boson (Z'_{SM}, Z_{LR}, Z_χ, Z_ψ, Z_η) on the top mass determination. The fit including Z' does not change the limit on m_t.

[46] The LEP 92 values are combined results of the four LEP collaborations: ALEPH, DELPHI, L3, and OPAL. The "Electroweak" result includes m_W and m_W/m_Z from ABE 90G and ALITTI 92B, and neutral current data from CDHS and CHARM. Uses α_s = 0.118 $\pm$ 0.008. Second error corresponds to m_H = 300$^{+700}_{-250}$ GeV.

[47] PDG 92 value comes from a fit by P. Langacker to recent data as discussed in the minireview above.

[48] RENTON 92 is a fit to LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. The second error is from m_H=300$^{+700}_{-250}$ GeV. $\alpha_s(m_Z)$ = 0.114 $\pm$ 0.007 is used. The 95%CL limit is 193 GeV. The fit to LEP data only gives m_t=142$^{+30}_{-37}$ $\pm$ 20 GeV.

[49] SCHAILE 92 performs fit to LEP electroweak data (as of summer 1991) as well as m_W (UA2/CDF) and νN (CDHS/CHARM). The second error is from m_H=300$^{+700}_{-250}$ GeV.

[50] The ABE 91B limit is derived from their m_W with m_Z = 91.161 GeV. Combining with the m_W measurement of ALITTI 90B, one obtains m_t < 230 GeV (95%CL).

[51] α_s = 0.115 $\pm$ 0.009. The second error is from m_{H^0} = 300$^{+700}_{-250}$ GeV.

[52] ALEXANDER 91F use α_s = 0.118 $\pm$ 0.008. The second error comes from m_H = 300$^{+700}_{-250}$ GeV.

[53] The 95%CL upper limit is 218 GeV.

[54] DELAGUILA 91C study bound on m_t in the presence of extra Z' (Z_{LR} and Z_χ) from various electroweak data. The upper bound on m_t is more strict for lower Z' masses. See their Fig. 2. See also DELAGUILA 92.

[55] GONZALEZ-GARCIA 91 result is based on low-energy neutral current data, Z mass and widths, m_W from ABE 90G. $m_{H^0} = 100$ GeV assumed.

[56] HIOKI 91 uses m_Z, $\Gamma_{\text{total}}(Z)$, and m_W. $m_{H^0} = 100$ GeV, $\alpha_s = 0.12$ assumed. For $m_{H^0} = 1$ TeV, one finds $m_t = 162^{+43}_{-46}$ GeV.

[57] LANGACKER 91 is a fit to various electroweak data. The second error is from $m_{H^0} = 250^{+750}_{-200}$ GeV. $\alpha_s = 0.12 \pm 0.02$ used. The 95%CL upper limit is 182 GeV [for $m_{H^0} = 1$ TeV]. For arbitrary Higgs structure, one obtains $m_t < 310$ GeV.

[58] ADACHI 90F limit is from R at PEP, PETRA, and TOPAZ at TRISTAN. Top mass dependence enters via radiative correction. Minimal standard model with $m_Z = 91.1$ GeV, $m_{H^0} = 100$ GeV assumed. $\Lambda_{\overline{\text{MS}}}$ is varied in the fit.

[59] ADEVA 90I analysis is based on m_Z measured by L3 and $\sin^2\theta_W = 0.2284 \pm 0.0043$ determined from m_W/m_Z and νN scattering data. $40 < m_H < 1000$ GeV assumed. The 1σ range is $m_t = 130^{+38}_{-42}$ GeV.

[60] BARGER 90C limit is a fit using only LEP and m_W data. $m_{H^0} = 100$ GeV assumed. The most likely value is $m_t = 151$ GeV. The limit increases to 225 GeV for $m_H = 1000$ GeV.

[61] BLONDEL 90 limit comes from $R_{\overline{\nu}} = \sigma^{\text{NC}}(\overline{\nu}N) / \sigma^{\text{CC}}(\overline{\nu}N)$ and R_ν. Comparison of R_ν and m_W (the latter from ALBAJAR 89 and ANSARI 87) gives an independent limit $m_t < 240$ GeV (90%CL).

[62] DECAMP 90P result is from m_Z, $\Gamma(Z \to \ell\ell)$, and m_W/m_Z from UA2 (ALITTI 90B), m_W from CDF (APS conf. '90), and νN neutral current data from CDHS and CHARM.

[63] ELLIS 90B limit is a fit to various electroweak data. $m_{H^0} = m_Z$ assumed. $m_c = 1.45$ GeV is used for νN data.

[64] KENNEDY 90 limit is a fit to neutral current data, W, Z masses, and Z widths. $m_H = m_Z$ assumed. For $m_H = 1$ TeV, the limit is 212 GeV. For nonminimal Higgs sector (with $\rho \neq 1$), one obtains $m_t < 350$ GeV (90%CL).

[65] ELLIS 89B limit is a fit to various electroweak data. $m_{H^0} = m_Z$ assumed. $m_c = 1.45$ GeV is used for νN data. Superseded by ELLIS 90B.

[66] LANGACKER 89 limit is a fit to various electroweak data. $m_{H^0} = 100$ GeV assumed. The 90%CL upper limit is 190(210) GeV for $m_{H^0} = 100(1000)$ GeV.

[67] COSTA 88 limit is a fit to various electroweak data. $m_{H^0} = m_Z$ assumed. $m_c = 1.5$ GeV is used for νN data.

[68] ELLIS 88C limit is a fit to neutral current data and W, Z masses. $m_{H^0} = m_Z$ assumed. $m_c = 1.45$ GeV is used for νN data. Varying m_c relaxes the limit to 185 GeV. Superseded by ELLIS 89B.

[69] FOGLI 88 limit is a fit to neutrino deep-inelastic scattering data.

[70] AMALDI 87 limit is a fit to various electroweak data. $m_{H^0} < 100$ GeV assumed.

MASS LIMITS for Top Hadrons in e^+e^- Collisions

The last column specifies measured quantities: S = Sphericity, T = Thrust.

For limits prior to 1987, see our 1990 edition, Physics Letters **B239**, p. VII.167 (1990).

[71] Search was near the Z peak at LEP.

[72] ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium-Z mixing parameter $\delta m^2 <$(10–30) GeV^2 (95%CL) for the mass 88–94.5 GeV. Using Richardson potential, a 1S toponium state is excluded for the mass range 87.9–88.7, 89.1–94.3 GeV. This range is very sensitive to the potential choice.

[73] Assumed $m_{H^+} < m_t - 6$ GeV.

[74] Superseded by ABREU 91F.

[75] AKRAWY 90B search was restricted to data near the Z peak at $E_{\text{cm}} = 91.26$ GeV at LEP. The excluded region is between 23.4 and 44.5 GeV if no H^+ decays exist.

[76] AKRAWY 90B limit applies for any H^+ branching ratio B($c\overline{s}$). Limit increases to 45.2 GeV if B($c\overline{s}$) = 1. The lower end of the excluded region is $m_{H^+} + 5$ GeV.

[77] The ABRAMS 89C limit from an isolated track search is 40.0 GeV.

[78] ADACHI 89C search was at $E_{\text{cm}} = 56.5$–60.8 GeV at TRISTAN using multi-hadron events accompanying muons.

[79] ENO 89 search at $E_{\text{cm}} = 50$–60.8 GeV at TRISTAN.

[80] ADACHI 88 set limit σ(top) < 8.2 pb at CL=95% for top-flavored-hadron production from event shape analyses at $E_{\text{cm}} = 52$ GeV. By using the quark-parton model cross-section formula with first-order QCD corrections near the threshold, the above limit leads to a lower mass limit of 25.8 GeV at 95% confidence level for top quarks.

[81] IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(t) < 0.15$ (95% CL) at $E_{\text{cm}} = 50$–52 GeV.

[82] SAGAWA 88 set limit σ(top) < 6.1 pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{\text{cm}} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 25.9 GeV for charge 2/3 quarks.

[83] ABE 87 set limit σ(top) < 16 pb at CL=95% for top-flavored hadron production, which should be compared with the full top-quark production cross section of 45.9 pb.

[84] YOSHIDA 87 set limit σ(top) < 17 pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{\text{cm}} = 52$ GeV. This limit should be compared with the full top-quark production cross section of 34 pb, which takes into account the effect of weak neutral current but neglects its axial-vector coupling contribution expected to be suppressed near threshold. After considering the radiative effects, top quarks of mass below 25.5 GeV can be excluded by the above limit.

Searches for b' (4^{th} Generation) Quark

MASS LIMITS for b' (4^{th} Generation) Quark or Hadron in $p\overline{p}$ Collisions

These experiments (except for MUKHOPADHYAYA 93) assume that no two-body modes such as $b' \to b\gamma$, $b' \to bg$, or $b' \to cH^+$ are available.

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
>85	95	[1] ABE	92	CDF	$\ell\ell$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>75	95	[2] MUKHOPAD...	93	RVUE	FCNC
>72	95	[3] ABE	90B	CDF	$e + \mu$
>54	95	[4] AKESSON	90	UA2	e + jets + missing E_T
>43	95	[5] ALBAJAR	90B	UA1	μ + jets
>34	95	[6] ALBAJAR	88	UA1	e or μ + jets

[1] ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to b' quarks, as discussed in ABE 90B.

[2] MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes $B(b' \to b\ell^+\ell^-)$=1%. For an exotic quark decaying only via virtual Z [$B(b\ell^+\ell^-)$ = 3%], the limit is 85 GeV.

[3] ABE 90B exclude the region 28–72 GeV.

[4] AKESSON 90 searched for events having an electron with $p_T > 12$ GeV, missing momentum > 15 GeV, and a jet with $E_T > 10$ GeV, $|\eta| < 2.2$, and excluded $m_{b'}$ between 30 and 69 GeV.

[5] For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

[6] ALBAJAR 88 study events at $E_{cm} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\overline{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

MASS LIMITS for b' (4^{th} Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b'.

The last column specifies the assumption for the decay mode ($C\,C$ denotes the conventional charged-current decay) and the event signature which is looked for.

[7] DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \to bg$ for $B(b' \to bg) > 65\%$ $b' \to b\gamma$ for $B(b' \to b\gamma) > 5\%$ are excluded. Charged Higgs decay were not discussed.

[8] ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium-Z mixing parameter $\delta m^2 < (10–30)$ GeV^2 (95%CL) for the mass 88–94.5 GeV. Using Richardson potential, a 1S ($b'\overline{b}'$) state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice.

[9] ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.

[10] Superseded by ABREU 91F.

[11] AKRAWY 90B search was restricted to data near the Z peak at $E_{cm} = 91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between (m_{H^+} + 1.5 GeV) and 45.5 GeV.

[12] AKRAWY 90J search for isolated photons in hadronic Z decay and derive $B(Z \to b'\overline{b}')\cdot B(b' \to \gamma X)/B(Z \to$ hadrons) $< 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \to \gamma X) > 10\%$.

[13] ABE 89E search at $E_{cm} = 56$–57 GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

[14] ABE 89G search was at $E_{cm} = 55$–60.8 GeV at TRISTAN.

[15] If the photonic decay mode is large ($B(b' \to b\gamma) > 25\%$), the ABRAMS 89C limit is 45.4 GeV. The limit for for Higgs decay ($b' \to cH^-$, $H^- \to \overline{c}s$) is 45.2 GeV.

[16] ADACHI 89C search was at $E_{cm} = 56.5$–60.8 GeV at TRISTAN using multi-hadron events accompanying muons.

[17] ADACHI 89C also gives limits for any mixture of $C\,C$ and bg decays.

[18] ENO 89 search at $E_{cm} = 50$–60.8 at TRISTAN.

[19] ENO 89 considers arbitrary mixture of the charged current, bg, and $b\gamma$ decays.

[20] IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4$ GeV.

[21] SAGAWA 88 set limit σ(top) < 6.1 pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{cm} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.

[22] ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR, as a function of the minimum c.m. energy (see their figure 3). Production of a pair of 1/3 charge quarks is excluded up to $E_{cm} = 45.4$ GeV.

[23] ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)B$(hadrons) <2.4 keV CL = 95% and heavy charge 1/3 quark pair production m >21 GeV, CL = 95%.

[24] ALTHOFF 84I exclude heavy quark pair production for 7 < m <19 GeV (1/3 charge) using aplanarity distributions (CL = 95%).

for $I = 0$ (η, η', h, h', ω, ϕ, f, f'): $c_1(u\bar{u} + d\bar{d}) + c_2(s\bar{s})$

NOTE ON PSEUDOSCALAR-MESON DECAY CONSTANTS

(by M. Suzuki, Lawrence Berkeley Laboratory)

Charged mesons

The decay constant f_P for pseudoscalar meson P is defined by

$$\langle 0|A_\mu(0)|P(\mathbf{q})\rangle = i f_P\, q_\mu \ ,$$

where A_μ is the axial-vector part of the charged weak current after a Cabibbo-Kobayashi-Maskawa mixing-matrix element $V_{qq'}$ has been removed. The state vector is normalized by $\langle P(\mathbf{q})|P(\mathbf{q}')\rangle = (2\pi)^3\, 2E_q\, \delta(\mathbf{q}-\mathbf{q}')$, and its phase is chosen to make f_P real and positive. Note, however, that in many theoretical papers our $f_P/\sqrt{2}$ is denoted by f_P.

In determining f_P experimentally, radiative corrections must be taken into account. Since the photon-loop correction introduces an infrared divergence that is canceled by soft-photon emission, we can determine f_P only from the combined rate for $P^\pm \to \ell^\pm\nu_\ell$ and $P^\pm \to \ell^\pm\nu_\ell\gamma$. This rate is given by

$$\Gamma(P \to \ell\nu_\ell + \ell\nu_\ell\gamma) = \frac{G_F^2|V_{qq'}{}^2|}{8\pi} f_P^2\, m_\ell^2\, m_P \left(1-\frac{m_\ell^2}{m_P^2}\right)^2 [1+\mathcal{O}(\alpha)] \ .$$

Radiative corrections contain an inner bremsstrahlung, which is independent of the structure of the meson [1–3], and a structure-dependent part [4,5]. After radiative corrections are made, there are ambiguities in extracting f_P from experimental measurements. In fact, the definition of f_P is no longer unique.

It is desirable to define f_P such that it depends only on the properties of the pseudoscalar meson, not on the final decay products. The short-distance corrections to the fundamental electroweak constants like $G_F|V_{qq'}|$ should be separated out. Following Marciano and Sirlin [6], we define f_P with the following form for the $\mathcal{O}(\alpha)$ corrections:

$$1+\mathcal{O}(\alpha) = \left[1+\frac{2\alpha}{\pi}\ln\left(\frac{m_Z}{m_\rho}\right)\right]\left[1+\frac{\alpha}{\pi}F(x)\right] \times\left\{1-\frac{\alpha}{\pi}\left[\frac{3}{2}\ln\left(\frac{m_\rho}{m_P}\right)+C_1+C_2\frac{m_\ell^2}{m_\rho^2}\ln\left(\frac{m_\rho^2}{m_\ell^2}\right)+C_3\frac{m_\ell^2}{m_\rho^2}+\ldots\right]\right\} .$$

Here

$$F(x) = 3\ln x + \frac{13-19x^2}{8(1-x^2)} - \frac{8-5x^2}{2(1-x^2)^2}\,x^2\ln x - 2\left(\frac{1+x^2}{1-x^2}\ln x+1\right)\ln(1-x^2) + 2\left(\frac{1+x^2}{1-x^2}\right)L(1-x^2) \ ,$$

with

$$x \equiv m_\ell/m_P \ , \qquad L(z) \equiv \int_0^z \frac{\ln(1-t)}{t}\,dt \ .$$

The first bracket in the expression for $1+\mathcal{O}(\alpha)$ is the short-distance electroweak correction. The QCD correction reduces this factor by 0.00033. The second bracket together with the term $-(3\alpha/2\pi)\ln(m_\rho/m_P)$ in the third bracket corresponds to the radiative corrections to the point-like pion decay ($\Lambda_{\text{cutoff}} \approx m_\rho$) [2]. The rest of the corrections in the third bracket are expanded in power of m_ℓ/m_ρ. The expansion coefficients C_1, C_2, and C_3 depend on the hadronic structure of the pseudoscalar meson and in most cases cannot be computed accurately. In particular, C_1 absorbs the uncertainty in the matching energy scale between short- and long-distance strong interactions and thus is the main source of uncertainty in determining f_{π^+} accurately.

With the experimental value for the decay $\pi \to \mu\nu_\mu + \mu\nu_\mu\gamma$, one obtains

$$f_{\pi^+} = 130.7 \pm 0.1 \pm 0.36 \text{ MeV} \ ,$$

where the first error comes from the experimental uncertainty on $|V_{ud}|$ and the second comes from the uncertainty on C_1 ($= 0 \pm 0.24$) [6]. Similarly, one obtains from the decay $K \to \mu\nu_\mu + \mu\nu_\mu\gamma$ the decay constant

$$f_{K^+} = 159.8 \pm 1.4 \pm 0.44 \text{ MeV} \ ,$$

where the first error is due to the uncertainty on $|V_{us}|$.

For the heavy pseudoscalar mesons, uncertainties in the experimental values for the decay rates are much larger than the radiative corrections. For the D^+, only an upper bound can be obtained from the published data:

$$f_{D^+} < 310 \text{ MeV (CL} = 90\%) \ .$$

Two groups have measured the $D_s^+ \to \mu^+\nu_\mu$ branching fraction, leading to the following values of the decay constant:

$$f_{D_s^+} = 232 \pm 45 \pm 20 \pm 48 \text{ MeV} \quad [7] \ ,$$

$$f_{D_s^+} = 344 \pm 37 \pm 52 \pm 42 \text{ MeV} \quad [8] \ ,$$

where the first errors are statistical, the second errors are systematic, and the third errors are uncertainties involved in extracting the branching fraction $\mathrm{B}(D_s^+ \to \mu^+\nu_\mu)$.

There have been many attempts to extract f_P from spectroscopy and nonleptonic decays using theoretical models. Since it is difficult to estimate uncertainties for them, we have listed here only values of decay constants that are obtained directly from the observation of $P^\pm \to \ell^\pm\nu_\ell$.

Light neutral mesons

The decay constants for the light neutral pseudoscalar mesons π^0, η, and η' are defined by

$$\langle 0|A_\mu(0)|P^0(\mathbf{q})\rangle = \mathrm{i}(f_P/\sqrt{2})q_\mu \ ,$$

where A_μ is a neutral axial-vector current of octet or singlet. Values of f_P can be obtained from the two-photon decay $P^0 \to \gamma\gamma$, since in the $m_P = 0$ limit the decay matrix element is determined by the Adler-Bell-Jackiw anomaly [9,10]. However, large uncertainties enter values of f_P through extrapolation to the physical mass and, in the case of η and η', through the mixing angle, too.

The CELLO Collaboration has obtained the values [11]

$$f_{\pi^0} = 119 \pm 4 \text{ MeV}$$

$$f_\eta = 133 \pm 10 \text{ MeV}$$

$$f_{\eta'} = 126 \pm 7 \text{ MeV} ,$$

while the TPC/2γ Collaboration has obtained [12]

$$f_\eta = 129 \pm 8 \text{ MeV}$$

$$f_{\eta'} = 110 \pm 7 \text{ MeV} .$$

(We have multiplied the published values by $\sqrt{2}$ to be in accord with our definition of f_P.)

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

NOTE ON THE CHARGED PION MASS*

The charged pion mass we give in this edition is three (old) standard deviations higher than the one we gave in our 1992 edition. This Note explains why.

Precise determinations of the charged pion mass come from two kinds of experiments: (a) measurement of the momentum of the muon in $\pi^+ \to \mu^+\nu_\mu$ decay at rest, assuming $m_{\nu_\mu} = 0$; and (b) measurement of x-ray wavelengths of transitions in pionic atoms. Technique (b) is free of assumptions about m_{ν_μ}.

For technique (b), the pionic-atom transition is chosen to achieve maximal spectrometer performance and minimal theoretical uncertainty. Experimenters have used the wavelengths of the $4f$-$3d$ transition in magnesium and the $5f$-$4d$ transition in titanium and phosphorous. Screening by K-shell ($1s$) electrons is significant, and the observed line profile is a blend of lines from atoms with 0, 1, and 2 K electrons present during the transition.

The best pionic-atom measurement of the pion mass in our recent editions was that of JECKELMANN 86B. Their observed line profile was measurably broadened by contributions from atoms having different $1s$ populations. Fits to the line profile gave two equally good solutions: One, with probabilities of about 27%, 70%, and 3% for 0, 1, or 2 K-shell electrons; and another, in which the state with two K electrons dominated. Using the ratio of $4f$-$3d$ and $3d$-$2p$ intensities and other experimental information, JECKELMANN 86B rejected the second solution.

Recent measurements now yield a smaller value for the intensity ratio [1], so that in a reanalysis of the data JECKELMANN 94 now consider that the grounds for rejecting the second solution are marginal. The new analysis is improved in other respects as well, including use of an improved wavelength calibration standard. The situation is now considered to be ambiguous, with both of the following solutions given equal footing:

$$\text{Solution A:} \quad m_{\pi^-} = 139.56782 \pm 0.00037 \text{ MeV}$$

$$\text{Solution B:} \quad m_{\pi^-} = 139.56995 \pm 0.00035 \text{ MeV}$$

See key on page 1343

The two solutions differ by about six times the uncertainty in either one. The ambiguity is expected to be resolved by future pionic x-ray measurements involving lighter atoms, where it is known with fair certainty that the K shell is almost empty during the pionic transition of interest. Such measurements on pionic oxygen and nitrogen at a pressure of a few bars have begun at the Paul Scherrer Institute [2]. We now give both Solutions A and B in the Listings below.

In the previous edition, we reported five $\pi^{\pm}$ mass measurements with uncertainties smaller than 0.005 MeV. These, together with the results from the new analysis, are shown in Fig. 1. Two of them, CARTER 76 and MARUSHENKO 77, have such large errors that there is no conflict with either A or B. JECKELMANN 86B was basically Solution A above, with a small difference (it was $0.8\,\sigma$ lower) because of the new analysis and revised wavelength calibration. DAUM 91 was based on technique (a), a measurement of the muon momentum from π^+ decay at rest. Since their reported mass was obtained by assuming $m_{\nu_\mu} = 0$, it is really a lower limit. It is in good agreement with Solution B but disagrees with Solution A, as we discuss further below. LU 80 is compatible with Solution A but not with Solution B or with DAUM 91. A screening correction used by LU 80 came from a theoretical calculation based on a 1961 paper by Eisenberg and Kessler [3]. It would now appear that the new intensity-ratio measurements call into doubt some of the earlier input assumptions.

The DAUM 91 measurement of the muon momentum from π^+ decay at rest has been further refined, and Assamagan *et al.* [4] report $p_\mu = 29.79207 \pm 0.00012$ MeV/c (this work has been submitted for publication). This result is close to their earlier value, but the error is much smaller. When this result is combined with Solution A, one obtains a value for $m^2_{\nu_\mu}$ that is negative by six standard deviations. By contrast, with Solution B, $m^2_{\nu_\mu}$ is negative by only about one standard deviation. (See the parallel discussion and graph in the m_{ν_μ} section of these Full Listings.)

On the grounds that $m^2_{\nu_\mu}$ ought to be nonnegative, we choose Solution B of JECKELMANN 94 as the $\pi^{\pm}$ mass. We do not average this with any other results, given the uncertainties. Obviously, however, the DAUM 91 (or Ref. 4) result determines our choice. Thus from the 1992 edition to this one, the mass has changed from 139.5679 ± 0.0007 MeV to 139.56995 ± 0.00035 MeV, a shift upwards of 0.00205 MeV, or three of the old standard deviations.

Since the π^0 mass comes from measurements of the $\pi^{\pm}$-π^0 mass difference, it too jumps upward.

[1] See the above "Note on the Charged Pion Mass" for a discussion of the two JECKELMANN 94 values.

[2] The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

[3] JECKELMANN 86B gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible $\pi^{\pm}$ masses.

[4] These values are scaled with a new wavelength-energy conversion factor $V\lambda = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

[5] This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

$m_{\pi^+} - m_{\mu^+}$

π^+ DECAY MODES

π^- modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Confidence level
Γ_1	$\mu^+\nu_\mu$	[a]	(99.98770±0.00004) %	
Γ_2	$\mu^+\nu_\mu\gamma$	[b]	(1.24 ±0.25) × 10^{-4}	
Γ_3	$e^+\nu_e$	[a]	(1.230 ±0.004) × 10^{-4}	
Γ_4	$e^+\nu_e\gamma$	[b]	(1.61 ±0.23) × 10^{-7}	
Γ_5	$e^+\nu_e\pi^0$		(1.025 ±0.034) × 10^{-8}	
Γ_6	$e^+\nu_e e^+ e^-$		(3.2 ±0.5) × 10^{-9}	
Γ_7	$e^+\nu_e\overline{\nu}$		< 5 × 10^{-6}	90%
	Lepton Family number (*LF*) or Lepton number (*L*) violating modes			
Γ_8	$\mu^+\overline{\nu}_e$	*L*	[c] < 1.5 × 10^{-3}	90%
Γ_9	$\mu^+\nu_e$	*LF*	[c] < 8.0 × 10^{-3}	90%
Γ_{10}	$\mu^- e^+ e^+\nu$	*LF*	< 1.6 × 10^{-6}	90%

[a] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ's. Therefore, since no clean separation is possible, we consider the modes with γ's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[b] See the Full Listings below for the energy limits used in this measurement; low-energy γ's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

[12] MCFARLANE 85 combines a measured rate (0.394 ± 0.015)/s with 1982 PDG mean life.

[13] DEPOMMIER 68 says the result of DEPOMMIER 63 is at least 10% too large because of a systematic error in the π^0 detection efficiency, and that this may be true of all the previous measurements (also V. Soergel, private communication, 1972).

NOTE ON $\pi^\pm \to \ell^\pm\nu\gamma$ AND $K^\pm \to \ell^\pm\nu\gamma$ FORM FACTORS

(by H.S. Pruys, Zürich University)

In the radiative decays $\pi^\pm \to \ell^\pm\nu\gamma$ and $K^\pm \to \ell^\pm\nu\gamma$, where ℓ is an e or a μ and γ is a real or virtual photon (e^+e^- pair), both the vector and the axial-vector weak hadronic currents contribute to the decay amplitude. Each current gives a structure-dependent term (SD_V and SD_A) from virtual hadronic states, and the axial-vector current also gives a contribution from inner bremsstrahlung (IB) from the lepton and meson. The IB amplitudes are determined by the meson decay constants f_π and f_K [1]. The SD_V and SD_A amplitudes are parameterized in terms of the vector form factor F_V and the axial-vector form factors F_A and R [1–4]:

$$M(\mathrm{SD}_V) = \frac{-eG_F V_{qq'}}{\sqrt{2}\,m_P}\epsilon^\mu \ell^\nu F_V \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau ,$$

$$M(\mathrm{SD}_A) = \frac{-ie\,G_F V_{qq'}}{\sqrt{2}\,m_P}\epsilon^\mu \ell^\nu \{F_A[(s-t)g_{\mu\nu} - q_\mu k_\nu] + R\,t\,g_{\mu\nu}\} .$$

Here $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; $\epsilon^\mu = (e/t)\overline{u}(p_-)\gamma^\mu v(p_+)$ is the polarization vector of the photon; $\ell^\nu = \overline{u}(p_\nu)\gamma^\nu(1-\gamma_5)v(p_\ell)$ is the lepton-neutrino current; q and k are the meson and photon four-momenta, with $s = q\cdot k$ and $t = k^2$; and P stands for π or K. The s and t dependence of the form factors is neglected, which is a good approximation for pions [2] but not for kaons [4]. The pion vector form factor F_V^π is related via CVC to the π^0 lifetime, $|F_V^\pi| = (1/\alpha)\sqrt{2\Gamma_{\pi^0}/\pi m_{\pi^0}}$ [1]. PCAC relates R to the electromagnetic radius of the meson [2,4], $R^P = \frac{1}{3}m_P f_P \langle r_P^2\rangle$. The calculation of the other form factors, F_A^π, F_V^K, and F_A^K, is model dependent [1,4].

When the photon is real, the partial decay rate can be given analytically [1,5]:

$$\frac{d^2\Gamma_{P\to\ell\nu\gamma}}{dxdy} = \frac{d^2(\Gamma_{\mathrm{IB}} + \Gamma_{\mathrm{SD}} + \Gamma_{\mathrm{INT}})}{dxdy} ,$$

where $\Gamma_{\mathrm{IB}}, \Gamma_{\mathrm{SD}}$, and Γ_{INT} are the contributions from inner bremsstrahlung, structure-dependent radiation, and their interference, and the Γ_{SD} term is given by

$$\frac{d^2\Gamma_{\mathrm{SD}}}{dxdy} = \frac{\alpha}{8\pi}\Gamma_{P\to\ell\nu}\frac{1}{r(1-r)^2}\left(\frac{m_P}{f_P}\right)^2 \times \left[(F_V+F_A)^2\,\mathrm{SD}^+ + (F_V-F_A)^2\,\mathrm{SD}^-\right] .$$

Here

$$\mathrm{SD}^+ = (x+y-1-r)\left[(x+y-1)(1-x)-r\right] ,$$

$$\mathrm{SD}^- = (1-y+r)\left[(1-x)(1-y)+r\right] ,$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$.

In $\pi^\pm \to e^\pm\nu\gamma$ and $K^\pm \to e^\pm\nu\gamma$ decays, the interference terms are small, and thus only the absolute values $|F_A+F_V|$ and $|F_A-F_V|$ can be obtained. In $K^\pm \to \mu^\pm\nu\gamma$ decay, the interference term is important, and thus the signs of F_V and F_A can be obtained. In $\pi^\pm \to \mu^\pm\nu\gamma$ decay, bremsstrahlung completely dominates. In $\pi^\pm \to e^\pm\nu e^+e^-$ and $K^\pm \to \ell^\pm\nu e^+e^-$ decays, all three form factors, F_V, F_A, and R, can be determined.

We give the $\pi^\pm$ form factors F_V, F_A, and R in the Listings below. In the $K^\pm$ Listings, we give the sum $F_A + F_V$ and difference $F_A - F_V$.

Meson Full Listings

$\pi^{\pm}, \pi^0$

The electroweak decays of the pseudoscalar mesons are investigated to learn something about the unknown hadronic structure of these mesons, assuming a standard $V-A$ structure of the weak leptonic current. The experiments are quite difficult, and it is not meaningful to analyse the results using parameters for both the hadronic structure (decay constants, form factors) and the leptonic weak current (*e.g.*, to add pseudoscalar or tensor couplings to the $V-A$ coupling). Deviations from the $V-A$ interactions are much better studied in purely leptonic systems such as muon decay.

π^0

$I^G(J^{PC}) = 1^-(0^{-+})$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

π^0 MASS

The value is calculated from $m_{\pi^\pm}$ and $(m_{\pi^\pm} - m_{\pi^0})$. The value of $m_{\pi^\pm}$ has gone up by three (old) standard deviations since our 1992 edition, and thus m_{π^0} has also jumped. See the "Note on the Charged Pion Mass" in the $\pi^\pm$ Listings.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 1.9 for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[7] This limit applies to all possible $\nu\nu'$ states as well as to other massless, weakly interacting states.
[8] LAM 91 considers the production of right-handed neutrinos produced from the cosmic thermal background at the temperature of about the pion mass through the reaction $\gamma\gamma \to \pi^0 \to \nu\overline{\nu}$.
[9] NATALE 91 considers the excess energy-loss rate from SN 1987A if the process $\gamma\gamma \to \pi^0 \to \nu\overline{\nu}$ occurs, permitted if the neutrinos have a right-handed component. As pointed out in LAM 91 (and confirmed by Natale), there is a factor 4 error in the NATALE 91 published result (0.8 × 10^{-7}).

π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \to e^+ e^- \gamma$ contains a form factor $F(x)$ at the $\pi^0 \gamma\gamma$ vertex, where $x = [m_{e^+e^-}/m_{\pi^0}]^2$. The parameter a in the linear expansion $F(x) = 1 + ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

LINEAR COEFFICIENT OF π^0 ELECTROMAGNETIC FORM FACTOR

[14] BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of a is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

[15] TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

[16] The FISCHER 78 error is statistical only. The result without radiation corrections is $+0.05 \pm 0.03$.

CONSTRAINED FIT INFORMATION

An overall fit to a decay rate and 14 branching ratios uses 40 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 31.2$ for 32 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

NOTE ON THE DECAY WIDTH $\Gamma(\eta \to \gamma\gamma)$

(by N.A. Roe, Lawrence Berkeley Laboratory)

In the measurements of $\Gamma(\eta \to \gamma\gamma)$ listed below, the results from two-photon production disagree with those from Primakoff production. Since the 1990 edition, one new two-photon measurement has been reported by MD-1; it is consistent with previous two-photon results, though the errors are somewhat larger. The weighted average of the two-photon measurements is 0.510 ± 0.026 keV, to be compared with the Primakoff-production measurement of BROWMAN 74B, 0.324 ± 0.046 keV.

In the two-photon measurements, η's are produced in the QED process $e^+e^- \to e^+e^-\gamma^*\gamma^* \to e^+e^-\eta$. The calculation of the rate is believed to be well understood. The uncertainty due to the virtual photon form factor is small; WILLIAMS 88 quotes an uncertainty of 0.2% from this source. Backgrounds to the η signal from beam-gas interactions and other two-photon interactions with missing particles are also small.

In the Primakoff experiments, η's are produced by the interaction of a real photon with a virtual photon in the Coulomb field of the nucleus. There is coherent background from strong production of η's in the nuclear hadronic field, and interference between the strong and Primakoff production amplitudes. The angular dependences of the Primakoff signal and the background are different, allowing $\Gamma(\eta \to \gamma\gamma)$ to be extracted from a fit to the angular distribution. In the best fit to their data, BEMPORAD 67 found the coherent hadronic background to be consistent with zero. BROWMAN 74B had a wider range of photon energies, a higher maximum energy, better angular resolution, and higher statistics. They found a significant contribution from the hadronic background, especially at lower

energies. BROWMAN 74B also reanalyzed the data of BEMPORAD 67 and found that it was compatible with their fit, including background terms. This suggests that the background was underestimated by BEMPORAD 67, and we consider their result to be superseded by that of BROWMAN 74B.

There remains the disagreement between the two-photon results and the result of BROWMAN 74B. The errors assigned by BROWMAN 74B include a 5.3% statistical error, a 12.2% systematic error for uncertainty in the accepted photon spectrum, and a 2.5% systematic error for uncertainty in the nuclear parameters used in the calculation of the Primakoff and nuclear form factors. The Primakoff form factor F_C is a function of the momentum transfer q and the production angle θ. As $q^2 \to 0$, the uncertainty in F_C due to the q^2 dependence vanishes. The minimum q^2 in this experiment ranged from -680 MeV^2 at the lowest energy to -174 MeV^2 at the highest. In this range, the result is sensitive to details in the calculation of F_C, but it is difficult to estimate the systematic error of this dependence. Another possible source of systematic error is in the phase of the interference term, ϕ. This was a free parameter in the fit, but was not well determined by the data because the interference contribution peaks in the same angular region as the Primakoff signal and so cannot be unambiguously separated by an angular fit. A reanalysis of the data would be necessary to determine whether any of these factors was overlooked in the determination of the systematic error.

Using the same apparatus, Browman *et al.* [1] measured $\Gamma(\pi^0 \to \gamma\gamma)$ to be 7.92 ± 0.42 eV, in good agreement with our world average of 7.7 ± 0.6 eV. (Our average includes the measurement of Browman *et al.*, but is dominated by a decay-length measurement by Atherton *et al.* [2] The error on the average involves a scale factor S=3.0 due to one outlying measurement.) However, the uncertainty due to F_C is reduced at lower momentum transfers, and q^2 was on the order of 100 times smaller in the π^0 measurement. The signal-to-background ratio is also larger, making the fit less sensitive to nuclear production.

A possible source of common systematic error in the two-photon experiments is the calculation of the two-photon luminosity function. However, WILLIAMS 88 measured the two-photon width of the π^0 as well as of the η, and their result, $7.7 \pm 0.5 \pm 0.5$ eV, is consistent with the world average quoted above.

To summarize, the two-photon measurements seem more reliable than the best Primakoff-production measurement. However, we include the latter in our average as there is no compelling reason to exclude it. The result, $\Gamma(\eta \to \gamma\gamma) = 0.46 \pm 0.04$ keV, is about one standard deviation from the average using only the two-photon measurements, 0.510 ± 0.026 keV, and the error is larger, due to the scale factor.

0.56 ±0.16	56	WEINSTEIN	83	CBAL	$e^+e^- \to e^+e^-\eta$
1.00 ±0.22		[1] BEMPORAD	67	CNTR	Primakoff effect

[1] BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

NOTE ON η DECAY PARAMETERS

C violation in η decays

A number of experiments have looked for charge asymmetries in $\eta \to \pi^+\pi^-\pi^0$ and $\eta \to \pi^+\pi^-\gamma$ decays. Any difference between the π^+ and π^- spectra in either decay would indicate C violation in electromagnetic interactions. Immediately following this Note, we list measurements of the following parameters:

(a) The left-right asymmetry

$$A = (N^+ - N^-)/(N^+ + N^-) ,$$

where N^+ is the number of events in which the π^+ energy in the η rest frame is greater than the π^- energy, *etc.*

(b) For the decay $\eta \to \pi^+\pi^-\pi^0$, the sextant asymmetry

$$A_s = \frac{N_1 + N_3 + N_5 - N_2 - N_4 - N_6}{N_1 + N_2 + N_3 + N_4 + N_5 + N_6} ,$$

where the N_i are the numbers of events in sextants of the Dalitz plot; see, for example, Layter *et al.* [1] A_s is sensitive to an I=0 C-violating final state.

(c) For the decay $\eta \to \pi^+\pi^-\pi^0$, the quadrant asymmetry

$$A_q = \frac{N_1 + N_3 - N_2 - N_4}{N_1 + N_2 + N_3 + N_4} ,$$

where the N_i are numbers of events in quadrants of the Dalitz plot. A_q is sensitive to an I=2 C-violating final state.

(d) For the decay $\eta \to \pi^+\pi^-\gamma$, evidence for a D-wave contribution to the C-violating amplitude. The upper limit for this contribution is measured by the parameter β, defined by

$$dN/d|\cos\theta| \propto \sin^2\theta(1 + \beta\cos^2\theta) ,$$

where θ is the angle between the π^+ and the γ in the dipion center of mass. A term proportional to $\cos^2\theta$ could also come from P- and F-wave interference.

Dalitz plot for $\eta \to \pi^+\pi^-\pi^0$

The Dalitz plot for $\eta \to \pi^+\pi^-\pi^0$ decay may be fit to the distribution

$$|M(x,y)|^2 \propto (1 + ay + by^2 + cx + dx^2 + exy) .$$

Here

$$x = \sqrt{3}(T_+ - T_-)/Q ,$$

$$y = (3T_0/Q) - 1 ,$$

where T_+, T_-, and T_0 are the kinetic energies of the π^+, π^-, and π^0 in the η rest frame, and $Q = T_+ + T_0 + T_-$. The coefficient of the term linear in x is sensitive to C violation due to an I=0 or I=2 final state. Below, we list papers that measured a, b, c, and d, but do not tabulate values of these parameters because the assumptions made by different authors are not compatible and do not allow comparison of the numerical values.

Dalitz plot for $\eta \to \pi^0\pi^0\pi^0$

The Dalitz plot for the decay $\eta \to \pi^0\pi^0\pi^0$ may be fit to

$$|M|^2 \propto 1 + 2\alpha z ,$$

where

$$z = \frac{2}{3}\sum_{i=1}^{3}\left(\frac{3E_i - m_\eta}{m_\eta - 3m_{\pi^0}}\right)^2 = \frac{\rho^2}{\rho^2_{max}} .$$

Here E_i is the energy of the i^{th} pion in the η rest frame, and ρ is the distance from the center of the Dalitz plot. We list measurements of the parameter α below.

$\rho(770)$

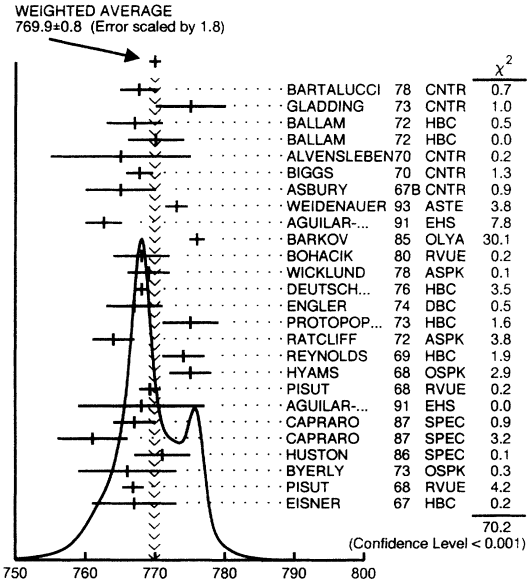
$\rho(770)$ $\quad I^G(J^{PC}) = 1^+(1^{--})$

Our latest mini-review on this particle can be found in the 1984 edition.

NOTE ON THE $\rho(770)$

Because of the large width of the $\rho(770)$, determination of the resonance parameters is beset with many difficulties. It is well known that in physical-region fits the line shape does not correspond to a relativistic Breit-Wigner function with a P-wave width, but requires some additional shape parameter. This dependence on parametrization was demonstrated long ago by PISUT 68, who showed that the mass was consistent with values between 761 MeV and 783 MeV to within two standard deviations. When mass values are quoted, as below, with one-standard-deviation errors, the conflicts between them are evident.

The same model dependence afflicts any other source of the resonance parameters, such as the energy dependence of the phase shift δ_1^1 or the pole position. It is therefore not surprising that a recent study of the $\rho(770)$ dominance in the decays of η and η' reveals the need for specific dynamical effects in addition to the $\rho(770)$ pole (BENAYOUN 93).



Recently LAFFERTY 93 has demonstrated that Bose-Einstein correlations is another source of shifts in the $\rho(770)$ line shape.

$\rho(770)$ MASS

We no longer list S-wave Breit-Wigner fits, or data with high combinatorial background.

ρ(770) RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1 + q_r^2 R^2) / (1 + q^2 R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

$\rho(770)$

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 9 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.2$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_3	−100		
Γ	18	−18	
	x_2	x_3	

	Mode	Rate (MeV)	Scale factor
Γ_2	$\pi^\pm\pi^0$	149.1 ±2.9	
Γ_3	$\pi^\pm\gamma$	0.068±0.007	2.3

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and a branching ratio uses 9 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 4.8$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[25] Possibly large ρ-ω interference leads us to increase the minus error.

[26] Result contains 11 ± 11% correction using SU(3) for central value. The error on the correction takes account of possible ρ-ω interference and the upper limit agrees with the upper limit of $\omega \to \mu^+\mu^-$ from this experiment.

[27] HYAMS 67's mass resolution is 20 MeV. The ω region was excluded.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 20 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 10.3$ for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 16 branching ratios uses 45 measurements and one constraint to determine 7 parameters. The overall fit has a $\chi^2 = 33.4$ for 39 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\eta'(958)$ $\Gamma(i)\Gamma(\gamma\gamma)/\Gamma(total)$

This combination of a partial width with the partial width into $\gamma\gamma$ and with the total width is obtained from the integrated cross section into channel(i) in the $\gamma\gamma$ annihilation.

$\Gamma(\gamma\gamma) \times \Gamma(\rho^0\gamma)/\Gamma_{total}$ $\Gamma_5\Gamma_2/\Gamma$

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a χ^2 = 2.0 for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$a_0(980)$ was $\delta(980)$

$I^G(J^{PC}) = 1^-(0^{++})$

NOTE ON THE $a_0(980)$

The proper $q\overline{q}$ assignment of the $a_0(980)$ scalar meson remains a problem. The observed mass and width seem to be inconsistent with those expected for a member of an $L = 1$ $q\overline{q}$ nonet. However, since the mass and width are distorted by the proximity of the $K\overline{K}$ threshold, the nature of the $a_0(980)$ can be better investigated using different experimental observations.

TORNQVIST 82 has shown that it is possible to understand the unusual experimental features of the $a_0(980)$ in a unitarized quark model. As with the $f_0(980)$, the $a_0(980)$ can be interpreted as a normal $q\overline{q}$ resonance with a large admixture of $K\overline{K}$, $\eta\pi$, and $\eta'\pi$ continuum states.

Assuming dominance of the decay $\eta'(958) \to \eta\pi\pi$ by a virtual $a_0(980)\pi$ intermediate state, BRAMON 80 concludes that the experimental value $\Gamma(\eta'(958) \to \eta\pi\pi) \approx 200$ keV is fully consistent with a $q\overline{q}$ interpretation. The same analysis also finds additional evidence in favor of this interpretation: If the $a_0(980)$ is a $q\overline{q}$ state, one expects that the decay chain $f_1 \to a_0(980)\pi \to \eta\pi\pi$ will be more important for the $f_1(1285)$ than for the $f_1(1420)$; the reverse is true if the $a_0(980)$ is a $q\overline{q}q\overline{q}$ state with a strange quark component. In fact, $f_1(1285) \to a_0(980)\pi \to \eta\pi\pi$ is observed, while $f_1(1420) \to a_0(980)\pi \to \eta\pi\pi$ is (practically) absent.

The main argument in favor of the $q\overline{q}q\overline{q}$ interpretation of the $a_0(980)$ is its degeneracy in mass with the isoscalar $f_0(980)$. A Crystal Ball measurement of $a_0(980) \to \gamma\gamma$ suppression in the reaction $\gamma\gamma \to a_0(980) \to \eta\pi$ (ANTREASYAN 86) has reinforced this four-quark interpretation. ACHASOV 88B points out that none of the calculations performed in the framework of a $q\overline{q}$ scheme can predict such a narrow $a_0(980) \to \gamma\gamma$ width as that found by the Crystal Ball. He then argues that the $a_0(980)$ is unusual and shows that a four-quark model is able to give the correct order of magnitude of suppression of 2γ production for both the scalar $a_0(980)$ and $f_0(980)$ mesons.

Another interesting non-$q\overline{q}$ interpretation is given by WEINSTEIN 83B, 89: The $q\overline{q}q\overline{q}$ system is investigated using the nonrelativistic quark model; assuming a large hyperfine interaction, the $a_0(980)$ and $f_0(980)$ are both interpreted as $K\overline{K}$ bound states, and then the P-wave $q\overline{q}$ states are all in the 1300-MeV region. With this S-wave $K\overline{K}$ mesonium assignment, many of the peculiar properties of the $a_0(980)$ and $f_0(980)$—masses, widths, branching fractions, and two-photon widths—make sense.

Meson Full Listings

$a_0(980)$

If the $a_0(980)$ is not the $^3P_0$ state, then this state should be observed near 1300 MeV, with partial decay widths close to the flavor symmetry predictions for an ideal nonet (TORNQVIST 90). The candidate $a_0(1320)$ reported by GAMS-4000 has the right mass, but the signal is weak under the dominant $a_2(1320)$, and its width is much smaller than expected.

See also the "Note on the $f_0(1300)$".

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 9 branching ratios uses 38 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 27.1$ for 33 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$a_1(1260)$ $I^G(J^{PC}) = 1^-(1^{++})$

NOTE ON THE $a_1(1260)$

For some time, even the existence of this broad bump as a genuine resonance in the 3π mass spectrum was questioned. Today the $a_1(1260)$ situation is still not satisfactorily understood, and its resonance parameters are not well determined. For an attempt to fit the leptonic data with two resonances, see IIZUKA 89.

The main experimental data on the $a_1(1260)$ can be grouped into two classes:

(1) Hadronic production—There are two high-statistics experiments: Diffractive production with incident π^- (DAUM 80, 81B) and charge-exchange production with low-energy π^- (DANKOWYCH 81), both on hydrogen. The extraction of the $a_1(1260)$ parameters from these experiments is troubled by the presence of coherent background, attributed to the Deck effect. Both experiments perform a partial-wave analysis. The phenomenological amplitude used to explain the 1^+S0^+ data consists of a rescattered Deck amplitude (calculated from one-pion exchange and not allowed to vary), plus a direct resonance-production term. Both experiments agree on a mass of about 1270 MeV, but DAUM 81B finds a somewhat smaller width than does DANKOWYCH 81 ($\simeq$ 300 MeV versus $\simeq$ 380 MeV). Rather lower values for the $a_1(1260)$ mass and width (1121±8 MeV and 239±11 MeV) have been obtained from a partial-wave analysis based on the isobar model of the $\pi^+\pi^-\pi^0$ system in a high-statistics π^-p charge-exchange reaction (ANDO 92). However, in this analysis, only Breit-Wigner terms were considered.

(2) τ decay—Four experiments have reported good data on $\tau \to a_1(1260)\nu_\tau$, $\to \rho\pi\nu_\tau$ (RUCKSTUHL 86, SCHMIDKE 86, ALBRECHT 86B, and BAND 87). Here the $a_1(1260)$ from τ decay is expected to be (almost) free from background. The four sets of data show some inconsistencies in the values quoted for the mass. However, according to BOWLER 86, this can be attributed to the different assumptions and approximations made in fitting the data. Furthermore, all these τ decays seem to indicate a consistent $a_1(1260)$ width greater than 400 MeV, considerably larger than that found by DAUM 81B. A recent analysis by ALBRECHT 93C on new ARGUS τ decay data confirms that the model-dependent systematic uncertainties of the parameters are much larger than the now small statistical errors.

The discrepancies between the hadronic and the τ decay results have stimulated several reanalyses. BOWLER 86, TORNQVIST 87, ISGUR 89, and IVANOV 91 have studied the process $\tau \to 3\pi\nu_\tau$ (BOWLER 86 has fit the data of ALBRECHT 86B and SCHMIDKE 86, while TORNQVIST 87, ISGUR 89, and IVANOV 91 have also used RUCKSTUHL 86).

BOWLER 86 assumes that the 3π state is wholly $a_1(1260)$, with no background, coherent or incoherent. His fits to the data always use the same theoretical form with a "normal" Breit-Wigner shape and various behaviors of the $a_1(1260)$ axial coupling as a function of the 3π mass.

TORNQVIST 87 fits a modified Breit-Wigner form to the data that includes, besides $\rho\pi$ and $K^*(892)\overline{K} + \overline{K}^*(892)K$ threshold effects, an energy-dependent real part of the $a_1(1260)$ mass parameter ("running mass shift function").

ISGUR 89 deduces a full mass-dependent covariant amplitude for $\tau \to 3\pi\nu_\tau$ from theory; all the ambiguities due to the non-pointlike nature of the hadrons (such as unknown off-shell behaviors of propagators and vertices) are associated with a parameterized nonresonant background amplitude. Since this background is small anyway, the $a_1(1260)$ parameters do not depend critically on its form.

Despite these quite different approaches, all three analyses find a good overall description of all the τ decay data with an $a_1(1260)$ mass near 1230 MeV, consistent with the hadronic data; however, their widths (400 MeV for BOWLER 86, 420 MeV for ISGUR 89, and 600 MeV for TORNQVIST 87) remain significantly higher than that extracted from diffractive-hadronic data.

IVANOV 91, using a phenomenological meson Lagrangian based on a four-quark interaction, obtains $a_1(1260)$ parameters consistent with those mentioned above.

BOWLER 88 returned to the diffractive data and investigated their consistency with an $a_1(1260)$ width greater than 400 MeV, as required by the τ-decay data. He verified that a width of about 300 MeV is a direct consequence of the particular fixed shape DAUM 81B used for the Deck amplitude. Freeing this shape, good fits are obtained with a width of about 400 MeV. He then finds no contradiction between the hadronic and τ-decay data, and the $a_1(1260)$ parameters are well constrained. However, applying the same type of analysis to the ANDO 92 data, the low mass and narrow width they obtained with the Breit-Wigner PWA do not change appreciably.

No evidence for charge-exchange photoproduction of the $a_1(1260)$ is observed by CONDO 93. This lack of evidence (together with a clear signal of $a_2(1320)$ photoproduction) is shown to be consistent with either an extremely large $a_1(1260)$ hadronic width or with a small radiative width $\Gamma[a_1(1260) \to \pi\gamma]$, which this could be accommodated if the a_1 mass is somewhat below 1260 MeV.

$f_2(1270)$

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 37 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 67.9$ for 30 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma(\gamma\gamma)$ Γ_7

The value of this width depends on the theoretical model used. Unitarised models with scalars give values clustering around $\simeq 2.6$; without an S-wave contribution, values are systematically higher (typically around 3). Since it is used to average results obtained with variety of models, we prefer to quote our own estimate.

<1.7	90	VOROBYEV	88	ND	$e^+e^- \to \pi^0\pi^0$

[13] From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
[14] Using a unitarized model with scalars.
[15] Using the unitarized model of LYTH 85.
[16] Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1300)$: $\Gamma(f_2) + 1/4\ \Gamma(f^0) = 3.6 \pm 0.3$ KeV.
[17] Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes 2.66 ± 0.21 in the calculation of LANDRO 86.
[18] Using the MENNESSIER 83 model.
[19] Superseded by BOYER 90.
[20] If helicity = 2 assumption is not made.
[21] Using mass, width and $B(f_2(1270) \to 2\pi)$ from PDG 78.

$f_2(1270)$ $\Gamma(i)\Gamma(\gamma\gamma)/\Gamma(total)$

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 13 measurements and one constraint to determine 6 parameters. The overall fit has a χ^2 = 11.4 for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i \delta x_j\rangle/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_3	−87				
x_7	−33	13			
x_8	−4	−5	−78		
x_9	46	−19	−38	−12

$f_0(1300)$
was $f_0(1400)$
was $\epsilon(1200)$

$I^G(J^{PC}) = 0^+(0^{++})$

We list here all claims for highly elastic $\pi\pi$ S-wave resonances.

NOTE ON S-WAVE $\pi\pi$, $K\overline{K}$, AND $\eta\eta$ INTERACTIONS

In this note, we discuss results on the nonstrange $I^G J^{PC} = 0^+0^{++}$ partial wave (S-wave). It has been observed in its coupling to the $\pi\pi$, $K\overline{K}$, $\eta\eta$, 4π, and $\eta\eta'$ systems. We list the claimed resonances under five separate entries covering the mass range from $\pi\pi$ threshold to about 1600 MeV: $f_0(980)$, $f_0(1300)$, $f_0(1370)$, $f_0(1525)$, and $f_0(1590)$. See also the Notes on the $a_0(980)$ and on Non-$q\bar{q}$ Mesons.

Below 1100 MeV, the essential contributions come from $\pi\pi$ and $K\overline{K}$ final states. The $I = 0$ S-wave $\pi\pi$ phase shift δ_0^0 (GRAYER 74, ROSSELET 77) shows a rapid step of 180° near the $K\overline{K}$ threshold, which is the $f_0(980)$ resonance, superimposed over a large "background" phase shift which reaches 90° a little above 1000 MeV. Above this energy, it continues to grow slowly, as expected for a very broad resonance. This is the $f_0(1300)$, which was the $f_0(1400)$ of our 1992 edition and which evolved from the $\epsilon(1200)$ (our 1976 edition). The $\pi\pi$ S-wave inelasticity is not accurately known, and the $\pi\pi \to K\overline{K}$ cross sections (COHEN 80, ETKIN 82, POLYCHRONAKOS 79, WETZEL 76) may have large uncertainties.

Using the data available in 1986, including data on $\pi^+\pi^-$ and K^+K^- central production (AKESSON 86) and on $J/\psi(1S) \to \phi\pi\pi$ and $J/\psi(1S) \to K^+K^-$, the coupled-channel analyses of AU 87 suggested that four resonances were needed to describe the 1-GeV region. But, adding to their analysis new data on $J/\psi(1S) \to \phi\pi\pi$ and $\phi K\overline{K}$ (MALIK 86, FALVARD 88, LOCKMAN 89), on $D_s^+ \to \pi^+\pi^+\pi^-$ (ANJOS 89), and on $K^+K^- \to K_S^0K_S^0$ (ASTON 88), and relaxing the constraints on $\pi\pi \to K\overline{K}$ cross sections (LINDENBAUM 92), MORGAN 93 now favors a single Breit-Wigner resonance for the $f_0(980)$ described by two poles, $E^{II} = (988 \pm 10) - (24 \pm 6)i$ MeV and $E^{III} = 978 - 28i$ MeV, corresponding to resonance parameters $m_0 = 983$ MeV, $\Gamma_0 = 52$ MeV, and $g^2_{K\overline{K}}/g^2_{\pi\pi} \approx 0.85$. In a similar coupled-channel analysis, but limited to fitting elastic-scattering data (GRAYER 74, ROSSELET 77), and the centrally produced $\pi\pi$ and $K\overline{K}$ data (AKESSON 86), ZOU 93 also finds two poles in the 1 GeV region, $E^{II} = 988 - 25i$ MeV in agreement with MORGAN 93, while their $E^{III} = 914 - 219i$ MeV, has a large imaginary part.

Below 900 MeV, BECKER 79B excludes a resonance behaviour for δ_0^0 in their $\pi^- p$ (polarized) $\to \pi^+\pi^- n$ data. In contrast, SVEC 92, using their data on $\pi^+ n$ (polarized) $\to \pi^+\pi^- p$, which only span the range 600–900 MeV, suggests a narrow scalar state at 750 MeV (Γ = 100–200 MeV); the associated δ_0^0 values differ substantially from the recent consensus and would reopen the old UP-DOWN ambiguity of the early 1970's (see our 1984 edition). The DOWN option was long ago selected by requiring continuity of δ_0^0 and its associated inelasticity above 900 MeV to reproduce the observed rapid variations of the $\pi\pi$ elastic cross sections through the $K\overline{K}$ threshold region (PROTOPOPESCU 73). Indeed, attempts to introduce an UP-type δ_0^0 tend to contradict dispersion relations (PENNINGTON 93). Thus, the interpretation of SVEC 92 must be treated with some reservation.

Both MORGAN 93 and ZOU 93 have to add a background term in the $f_0(980)$ region, which may be interpreted as a very broad ($\Gamma \approx 700$ MeV) resonance with mass in the 1000–1500 MeV range. Many broad $\pi\pi$ elastic resonances have been claimed in the 1000–1500 MeV region, and we collect them all under one entry, the $f_0(1300)$.

Above 1200 MeV, there is increasing evidence that the 0^+0^{++} sector is dominated by the 4π channel and that the $\eta\eta$ channel cannot be neglected. For the 4π channel, the information comes mainly from the analysis of $\bar{p}n \to 5\pi$ (GASPERO 93, ADAMO 93, AMSLER 94). AMSLER 94 finds a large production of a 0^{++} resonance decaying into 4π, mostly $\rho\rho$, with $M = 1374 \pm 38$ MeV and $\Gamma = 357 \pm 61$ MeV, and quote a 4π:2π

branching ratio of order 5:1. The same resonance is observed in $\overline{p}p \to \eta\eta\pi^0$ (AMSLER 93C) and in $\overline{p}p \to 3\pi^0$ (AKER 91) leading to an $\eta\eta$:$\pi\pi$ branching ratio of order 1:3.

Thus we collect all the broad $\pi\pi$ inelastic S-wave resonance claims under a new entry, the $f_0(1370)$, although they could be the $f_0(1300)$, provided the inelasticity of the latter is in fact larger than is presently believed.

In a simultaneous fit to the $\overline{p}p \to 3\pi^0$ and $\overline{p}p \to \eta\eta\pi^0$ data, ANISOVITCH 94 find again the $f_0(1370)$ and, in addition, they observe another scalar resonance with $M = 1520 \pm 25$ MeV and $\Gamma = 146 \pm 25$ MeV. We list this observation under the $f_0(1525)$, although it perhaps does not belong there.

The fifth scalar entry is the $f_0(1590)$ of the GAMS collaboration (BINON 83).

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 9.3 for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$f_1(1420)$

$I^G(J^{PC}) = 0^+(1^{++})$

See also minireview under non-$q\bar{q}$ candidates.

NOTE ON THE $f_1(1420)$

This particle is the axial-vector component of the old puzzling E/ι, which has caused much trouble.

In hadron-induced reactions, the $f_1(1420)$ is observed in centrally produced $K\overline{K}\pi$ systems obtained with π and p beams (DIONISI 80, ARMSTRONG 84, 89). A Dalitz-plot analysis gives its quantum numbers and the dominant decay mode. For instance, ARMSTRONG 89 finds that the signal is totally consistent with being an 1^{++} state with a dominant quasi-two-body S-wave decay into $K^*(892)\overline{K}$; furthermore, no 0^{-+} or 1^{+-} waves are required to fit the data. A G parity of +1 is suggested by the positive interference between the two overlapping $K^*(892)$ (ARMSTRONG 84). No significant signals in the $\eta\pi\pi$ or 4π decay modes are found in centrally produced 4π systems (ARMSTRONG 89G). All of this is in line with the previous observations made in $\overline{p}p$ annihilations.

In $\gamma\gamma$ fusion from e^+e^- annihilations, a signal at about 1420 MeV is seen only in single-tag events (AIHARA 86C, GIDAL 87B, BEHREND 89, HILL 89), where one of the two photons is off the mass shell; by contrast, it is totally absent in the untagged events where both photons are real and hence they cannot produce a spin-1 meson, because of the Yang-Landau theorem. This clearly implies $J = 1$ and $C = +1$. As for the parity, AIHARA 88B, 88C (same analysis as AIHARA 86C, with 25% more events) and BEHREND 89 all find angular distributions with positive parity preferred, but negative parity not excluded.

Although some uncertainties still remain, the state seen in hadronic interactions and that seen in spacelike virtual photon fusion from e^+e^- annihilations are often identified with one another since there are more similarities than differences. In particular, all experiments agree that this state appears only in $K^*(892)\overline{K}$. The same conclusions are obtained from partial wave analyses of $J/\psi(1S) \to \gamma K\overline{K}\pi$ (BAI 90C, AUGUSTIN 91).

BITYUKOV 88 studied the radiative decay $1^{++} \to \phi\gamma$. Since the ϕ is (almost) a pure $s\bar{s}$ state, the $\phi\gamma$ decay seems to be a good analyser to extract the $s\bar{s}$ component in the wave function of the decaying meson. Finding the $f_1(1285)$ but not the $f_1(1420)$, BITYUKOV 88 concludes that the $f_1(1420)$ cannot be the $s\bar{s}$ isoscalar member of the $q\bar{q}$ nonet containing the $f_1(1285)$. On the other hand, AIHARA 88C argues that, assuming they both belong to the same nonet and using several hypotheses, the octet-singlet mixing angle obtained is compatible with the $f_1(1420)$ being mostly $s\bar{s}$ and the $f_1(1285)$ being mostly $(u\bar{u}+d\bar{d})/\sqrt{2}$, although both require large admixtures of other $q\bar{q}$ components.

Arguments favoring the possibility the $f_1(1420)$ is a hybrid $q\bar{q}g$ meson or a four-quark state are put forward by ISHIDA 89 and by CALDWELL 90, respectively.

LONGACRE 90 argues that this particle is inconsistent with a QCD arrangement of quarks and gluons. He then develops a final-state rescattering mechanism with successive interactions between a K, a $\overline{K}$, and a π. The $f_1(1420)$ would then be a molecular state formed by the π orbiting in a P wave around an S-wave $K\overline{K}$ state.

$\eta(1440)$ was $\iota(1440)$

$I^G(J^{PC}) = 0^+(0^{-+})$

See also the mini-review under non-$q\bar{q}$ candidates. (See the index for the page number.)

NOTE ON THE $\eta(1440)$

The first observation of a meson with $I^GJ^{PC} = 0^+0^{-+}$ in the 1400-MeV mass region was made with $p\bar{p}$ annihilations at rest (BAILLON 67) in the channel $\eta(1440) \to K\overline{K}\pi$. It was seen to decay equally into $a_0(980)\pi$ and $\overline{K}^*(892)K$.

The $\eta(1440)$ has since also been seen in other hadronic reactions: In a partial-wave analysis of the $\eta\pi^+\pi^-$ system, confirming the decay $\eta(1440) \to a_0(980)\pi$ (FUKUI 91C); in a partial-wave analysis of the $K\overline{K}\pi$ system (CHUNG 85, BIRMAN 88); in 6-GeV $p\bar{p}$ annihilations (REEVES 86); and in nonperipherally selected $\pi^-p \to K^0_SK^0_S\pi^0n$ (RATH 89). RATH 89 favors the interpretation that there are two narrow η resonances in the 1410–1480 MeV region.

Neither the $\eta(1440)$ nor the $f_1(1420)$ are observed in the $s\bar{s}$-enriched peripheral reaction $K^-p \to K\overline{K}\pi\Lambda$ at 11 GeV/c (ASTON 87), which speaks against an $s\bar{s}$ interpretation of either state. Moreover, the $\eta(1440)$ is not seen by ARMSTRONG 84, 89 either, who studied $K\overline{K}\pi$ central production in $\pi^+p \to \pi^+(K\overline{K}\pi)p$ and $pp \to p(K\overline{K}\pi)p$ at 85 and 300 GeV/c [but the $f_1(1420)$ is seen]. This agrees with earlier results (DIONISI 80, DEFOIX 72, DUBOC 72, LORSTAD 69, *etc.*).

The $\eta(1440)$ is also seen as a broad enhancement in $J/\psi(1S)$ radiative decay. In the $K\overline{K}\pi$ channel, however, its mass is higher than observed in hadronic interactions, and its width is larger. It has been shown (TOKI 87, BAI 90C) that two resonances (with $M \approx 1420$ MeV and $M \approx 1490$ MeV) give a better description of the data. Moreover, the $\eta\pi^+\pi^-$ channel peaks near 1400 MeV (AUGUSTIN 90, BURCHELL 91). All these results suggest the existence of two overlapping states (favored by RATH 89 in hadronic production), one around 1400 MeV decaying into both $K\overline{K}\pi$ and $\eta\pi\pi$, the other one around 1490 MeV seen only in $K\overline{K}\pi$. Other possible decay modes, in $\pi\pi\gamma$ and 4π, are not sufficiently well established to clarify the situation.

There is considerable confusion on the partial decay modes: The $K\overline{K}\pi$ final state is usually dominated by $\overline{K}^*(892)K$ and/or $a_0(980)\pi$ contributions, but it is impossible to quote any reliable $\overline{K}^*K$ and $a_0\pi$ branching ratios, since the analyses are highly model dependent and the experiments do not agree.

We continue to list under the $\eta(1440)$ all the results on the 0^{-+} system in the 1380–1490 MeV region, but keep in mind that it is likely that there is more than one resonance present in these observations. The masses and widths are given separately according to the various decay modes.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 2 branching ratios uses 13 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.0$ for 9 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i\delta p_j\rangle/(\delta p_i\cdot\delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$X(1600)$

$I^G(J^{PC}) = 2^+(2^{++})$

OMITTED FROM SUMMARY TABLE

Observed in the reaction $\gamma\gamma \to \rho^0\rho^0$ near threshold. The large ratio of cross-sections $\sigma(\gamma\gamma \to \rho^0\rho^0) / \sigma(\gamma\gamma \to \rho^+\rho^-) \approx 4$ and the dominance of the $J^P = 2^+$ wave in the reaction $\gamma\gamma \to \rho^0\rho^0$ is a signature consistent with the production of an exotic ($I = 2$) resonance. Needs confirmation.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 1.9 for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[14] Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.
[15] Uses same data as HYAMS 75 and BECKER 79.
[16] From a phase shift solution containing a $f'_2(1525)$ width two times larger than the $K\overline{K}$ result.
[17] From phase-shift analysis. Error takes account of spread of different phase-shift solutions.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 14.7 for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_3	−77		
x_5	−74	17
